But if this arch be the homologue of a rib, the next question is, of what rib? In the crocodile the scapula are not attached to a vertebra; but they cannot belong to the neck or back, since each cervical and dorsal vertebra has its costal appendage; so that the occipital vertebra is the only incomplete segment, and, therefore, the only one to which they can belong. Again, in the lepidosiren, and most fish, they are attached to the occiput, and support an anterior limb; hence, in the reptile, they are merely displaced from their proper attachment.

The limb attached to this occipital scapular arch is next traced, from a small appendage in fish and low reptiles, through its rudimentary condition in the apteryx, or wingless bird, to the ordinary form. It is thus finally shown, that "the human hands and arms are parts of the head,—diverging appendages of the costal or hæmal arch of the occipital segment of the skull."

The pelvic extremities are next considered. Like the axiom in mathematics, "things that are equal to the same are equal to one another," so in homological anatomy, what is generally homologous to a given bone, bears the same relation to its special and serial homologues. If the scapular arch and the arm have this correspondence with the vertebra, the pelvis and the leg which are its homologues, will possess the same relation. This, however, is not relied on by the Author, but an elaborate independent proof is given. For this we refer the reader to the work itself.

Indeed, these brief remarks have barely sketched the principal argument, each part of which involves many others. Brief and imperfect as this notice necessarily is, it would have been far easier to have acquainted the reader with the points established in this work, and to have given the results without the toil of thought. We especially regret, that failing space prevents our attempting to adjudicate the precise shares of different anatomists in the great results

here presented. Suffice it to say, that while philosophical anatomy increases the already large debt that we owe to our kindred, the great German nation, still a large portion of the work is original, in the strict sense, being the result of the Author's personal observations, and equally original deductions. And on the whole, it may be safely asserted, that the little book before us constitutes one of Professor Owen's highest claims to the scientific eminence which he so deservedly possesses.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON.

October, 8, 1849.

Francis Hird, Esq., President.

The subject of larvæ passed from the intestines again became the subject of conversation, Dr. Crisp having exhibited those he mentioned at the last meeting, and which he believed to be too large for larvæ of the ichneumon. Mr. Skegg was attending the patient for a dyspeptic affection. There was no irritation of the bowels.

Dr. Bird said, that in some parts of Ireland, where deep ignorance prevails, there is a sad custom among the people when they are ill, of sending to the grave of some saint, obtaining a portion of the earth, and either eating or drinking it. The result is, that the larvæ of the churchyard beetle is swallowed. It is also possible, from eating raw vegetables or salads that eggs may be swallowed. From the appearance of the larvæ now exhibited they resemble those of the colyophthefous tribe.

Dr. Crisp also mentioned the case of a girl who had eat large quantities of snails, and voided something which Dalrymple recognised as the larvæ of the snail, but which turned out to be the undigested remains of the organs of generation of that creature. In allusion to the cases mentioned by Dr. Bird, he had doubts of their correctness; for he questioned whether those eggs would remain long in the alimentary canal without being formed into beetles.

Dr. Bird then called the attention of the Society to an exceedingly useful help to the medical practitioner in the shape of a vapour-bath, which he exhibited, and which had been used by him in his practice with great success. The great drawback to vapour baths had been their expense or inefficacy. Duval's apparatus had enabled the practitioner to apply any vapour; this was on the same principle, but recommended itself on account of its extreme convenience and great economy. The maker of it was Mr. Moss, of Bartholomew-square, Old-street. After showing the various appliances of which it was possessed, Dr. Bird mentioned three peculiar cases which had occurred to him in the last twelvemonth, the first of which had considerably perplexed him. It was that of a boy, now in hospital for another complaint, two years and a-half old. The patient looked well and generally healthy, as far as development was concerned, but the countenance showing great anxiety. The mother brought him completely doubled up in her lap, without the power of moving the limbs. He learned that the boy had been exposed to cold water, and that shortly after this he had the general appearances of cold, and was found to labour under total incapacity of bending his legs. He was an amiable child, and only petulant from extreme agony. He had never seen such a countenance, and the moment he was touched his shrieks were heart-rending. He had all the appearance of acute rheumatism, but had no swelling of the joints. There was great feverish excitement. He had looked for any spinal affection, but none could be detected, and he was induced to set the case down to acute rheumatism. He was in hospital several days; the perspiration was cold and clammy, and under the impression mentioned, he ordered him to be subjected to the vapour-bath for half an hour, after which he was capable of moving the joints a little; and the child, in ten days, was running about the ward. In the last twelve months, he (Dr. Bird) had had two similar cases, and the heart being examined, there was the smallest possible *frottement*. These were cases quite undefined, and were only remarkable for the severity of the pain and the readiness with which they were cured. He thought that the cases were connected with local fever. The urine in two of the cases contained urate of ammonia, diffused through it, and was of a milky appearance.

Mr. Headland thought that Dr. Bird was not happy in associating his cases with rheumatism. He had had a case, which he would not so associate, but it was curious. A young lady at boarding-school was unable to move the right arm; on looking at it, the head of the humerus was in the armpit, the arm having the appearance of dislocation into the axilla. On taking hold of it he found all the muscles rigid, but this did not apply to the wrist. She had received no injury—it had gradually stiffened. She appeared in fair health; her appetite was good; the catamenia regular; and her appearance robust. He could get no explanation of this condition, but that she had been of late rather anxious about her studies. He succeeded in relaxing the muscles and in bringing the arm back into the glenoid cavity, but the bone again glided into the axilla. It struck him that the condition must be dependent on the state of the nervous system, and on that supposition she was treated. She was ordered to be well nourished, the shower bath to be applied, and gentle friction to the limbs; but without improvement. At last there was a certain amount of improvement; the bone rested on the edge of the glenoid cavity, and in that condition it remained for some time. He thought it was a case of nervous irritability, and in the end, the use of sea water and change of air restored the limb to its normal condition, without the use of medicine.

Dr. Bird thought the case of Mr. Headland a most unique one; but he saw no analogy between it and the three cases which he had mentioned, in which there was intense tenderness, and the agony was continuous. In the one case the patient was placed under the influence of the bath, and whilst so placed there was for the first time power of extending the limb. There was not much chance here of confounding the post hoc with the propter hoc.

Dr. Bennet: There are cases of hysteria which are more nearly allied to Dr. Bird's cases than that of Mr. Headland. I had a lady under my care for months who presented a remarkable example of this. The first indication of it was after her confinement. She had some affection of the bladder, which I took to be the result of an injury after parturition, but it turned out to be an hysterical affection of the bladder. When I first saw her she was in good health and menstruating regularly; but she was afterwards attacked with a painful affection of the ankle-joints, which were not swelled, but tender. I gave a very positive opinion that there was no rheumatism, and no injury of the ankle-joint, and that she would do well. She went to the sea-side, has now returned, and again become pregnant, since which she had been improving. There never was the slightest indication of true inflammatory action, and in proportion as she gained strength to the nervous system she improved. I had submitted her to the action of the electro-magnetic machine, and she seemed a little better under its influence. Her condition lasted for many months.

WESTMINSTER MEDICAL SOCIETY.

October 20, 1849.

F. Hird, Esq., President.

Mr. Clarke exhibited a stem-pessary, fixed to a wire frame, and kept *in situ* by bands passing over the shoulders.

Mr. Nunn exhibited a drawing of a fungus growing inside the bladder, in a patient who had died of cholera, and in whom the only symptom of disease was, the occasional passing of blood per urethram during five years, and the increased flow of blood whenever a catheter was introduced. Connecting this case with one brought before the Society last year, he thought that where hæmaturia is increased by the use of instruments, and where no symptoms exist to indicate the seat of the disease, fungus of the bladder may be anticipated.

Mr. W. F. Barlow read a paper on the muscular contractions, occasionally found after death from cholera. He narrated two cases, in which the muscles of the arms, chest, and legs, and, in one instance, of the face, had been affected; some of the movements resembling those of volition. In one case, the movements began two minutes after death, in the other, a quarter of an hour, the muscles of the legs being the first affected. Two cases on record in India were referred to as being very similar. The movements might be confined to one part only, or even only to a particular muscle, or part of a muscle. He had endeavoured, but unsuccessfully, to excite the contractions by "pricking," and by the application of hot water. The Author alluded to the terror these movements occasion to the relatives, especially if they are uneducated, from the belief they excite that life still exists. He offered no explanation of the cause of these movements, but expressed a wish that they should be carefully noted, and all the different forms of movement placed on record. The time of their duration was of great importance.

Dr. Sibson commenced the adjourned discussion by saying, that having seen a great deal of cholera in Edinburgh in 1832, he felt more despair in his mind from this than from any other disease; the more we hear and see of it, the less we know. It had not been grasped in its whole extent, in its raging at one time, in hot weather, at another equally destructive in cold; here, in the last six months, we find that it increased in dry weather and diminished after the weather changed. It prevails most where there is destitution, want of food, of water, of cleanliness, &c.; and this is true throughout England. The number of victims it seized increased and decreased simultaneously with its progress in London. This appears to be its general law, but this condition of circumstances is not its cause, because typhus fever follows the same track on the map, yet rises and falls at different periods. At Moscow and St. Petersburg, and also in Canada, it raged during intense cold; recently its intensity in England and America has been simultaneous, yet different at Paris and other places, although the climatorial influences are apparently similar. He considered Dr. Snow's theory to be good, but not universally so. If the communicating particles exist in the air, how does cholera arise at one time, and typhus fever at another. He protested strongly against the mucous membrane being the primary seat of cholera. We are not yet in a condition to say that we can cure cholera in its first stage, for some patients pass at once into the depth of the disease; the disease has not been proved to be in the blood at first; that it is at a later period is very certain. In a number of cases in which he had injected salt and water in 1832, revival from collapse was permanently established by three or four injections; they afterwards died, from the urea in the blood not being excreted. The muscular movements, described by Mr. Barlow, are not peculiar to cholera; they depend upon the state of the blood after death. When a patient is rapidly destroyed by a disease, the extremities will often move after death, from the controlling influence of the nerves being removed.

Dr. Lankester considered that the increase in the mortality from cholera this year over that in 1832, is due to the great neglect of sanitary regulations in general; the population being double what it was—the mortality treble. The causes of cholera are, doubtless, complicated, not single; there must be a peculiar poison, predisposing and exciting causes, and a mode of transit of the poison from one person to another. Dr. Snow's theory is that of modified contagion; but he has not proved the existence of a poison in the water. He (Dr. Lankester) is now fully acquainted with Messrs. Brittan and Swayne's corpuscles; as is also Mr. Busk, who divides them into three classes; a few 1-500 to 1-1000 inch in diameter have a regular

shape; the others cannot be defined sufficiently. Those of the first class, are sporules of the smut of wheat; these are found in Dr. Swayne's specimens, not in those of Mr. Brittan; of the second class are the inner coating of the grains of wheat, which is constantly found in the seconds flour, and also occasionally in the best; the others are starch granules, which in some positions under the microscope exactly resemble annular cells. The drawing of Dr. Budd's is not sufficient to prove the existence of organisms; hence he had been compelled to fall back upon some poison still unknown. That a communicability of the disease from one person to another exists, he has no doubt, and referred, in proof of this, to the Rev. Mr. Thorpe's cases, published in the *Lancet*.

Dr. King had recognised two kinds of cholera evacuations; one like thin raspberry jam, the other dysenteric; of the first kind, all the sufferers died; the others all recovered. He had been very particular what his patients ate; and therefore no cholera granules had been found in their evacuations. He doubted much the passing of diarrhœa into cholera, as eleven visiters during twenty-four days only reported five such cases. He considered that the water was a great means of propagating the cholera; but the disease is not solely of the mucous membrane. Where there is collapse, the disease might arise, as Dr. Snow supposes; but where the blue colour prevails, he thought the blood was poisoned. In this way he expected to be able to prove two distinct forms of the disease.

Dr. James Bird did not despair of illustrating the disease if facts are sufficiently made known. He regretted to see medical men looking for a specific. Where the cholera prevails epidemically in India, as in the marching of troops, no such cause of the disease can exist as supposed by Dr. Snow. He believed that it spreads by human intercourse. He feared that Mr. Rogers, Editor of the *Medical Journal*, published at Madras, has drawn conclusions which the facts scarcely authorise. For example, he speaks of the pilgrims and troops conveying the disease, yet he denies its contagiousness. He regards cholera as resembling yellow fever, which, arising from endemic causes, under certain states of the air, becomes epidemic, maintaining, however, its predilection for low wet grounds. He referred to several instances on record of the endemic fever of Sierra Leone becoming contagious, and of the cholera spreading by the intercourse of soldiers in the small huts forming their barracks; hence it was ordered that every regiment should encamp in an open spot, and not go into these huts.

Dr. Webster, in his reply, spoke of the enormous elevation of many churchyards in London by the accumulation of corpses—St. James's, Piccadilly, and St. Bride's, for example, being raised to the height of above the first floor of the adjoining houses. 45,000 bodies have been yearly buried in these churchyards since 1831, exclusive of those taken to the cemeteries, making a total of upwards of 800,000 corpses accumulated in London during these 18 years. He showed that if the same number only continue to be interred during the next 50 years, more than two millions of bodies will be putrifying in these confined spots, contaminating the air and soil all around.

Dr. Snow, in reply, showed how the first cases in London might all have arisen from the use of Thames water, as supposed by his theory of the propagation of cholera.

At the next meeting Professor Murphy will read a paper on the use of Chloroform in Midwifery.

FUNGOUS THEORY OF CHOLERA.

[To the Editor of the Medical Times.]

SIR,—The importance which has recently been attached to the observation of peculiar cells, probably belonging to the lower orders of vegetable organisms, in the dejections of Cholera, induces me to lay before the Profession a few facts as to the occurrence of similar structures under other circumstances, in the fluids and tissues of the human body. In detailing these facts, I am placed under the disadvantage of writing at a distance from my memoranda and drawings; but the accuracy of the following statements may nevertheless be relied on, and the phenomena, which I believe to be by no means rare, will, in all probability, be soon the subject of sufficiently numerous observations, to place the real nature and pathological significance of the bodies described by Mr. Brittan and Mr. Swayne beyond doubt.

The occurrence, even in tolerably fresh urine, of circular bodies, from the size of blood globules upwards, which, from their resistance to chemical re-agents and their defined outline, appear to resemble the sporules of confervæ, is common in various states of disease, and perhaps in healthy urine under some particular circumstances. But it has also not unfrequently occurred to me to observe cells of a larger size, up to the 1-60th or 1-80th of a line in diameter, and presenting the distinct double margin which is characteristic of Mr. Brittan's "annular bodies." They usually present considerable refractive power, are imperfectly transparent, sometimes granular or presenting nuclei, and have somewhat of a straw colour, and a remarkably distinct edge. They have commonly been associated with the smaller bodies above-mentioned, and, in one instance they were accompanied by distinct and abundant ramifications of a mycodermatous vegetation, evidently from mould either generated in the urine or accidentally introduced into it. Some of the specimens of which I have drawings resemble so closely those in Mr. Brittan's figures, (*Medical Gazette*, Sept. 28.) that it would be impossible to point out any essential difference; and the opportunity I have had, through the kindness of Dr. W. Budd, of examining the cholera bodies themselves, enables me to speak confidently as to the exact resemblance of these to the cells seen by me in urine.

These structures were observed and drawn by me at least eighteen months ago long before the first cases of Cholera occurred; and they have since been repeatedly seen. As I have never observed them, however, in perfectly fresh urine passed into a perfectly clean vessel, I always considered them as probably due either to the effects of incipient decomposition or of accidental impurity; the more so as they did not appear to be connected with any special morbid condition of the secretion. The difficulty of removing all accidental sources of fallacy may be illustrated by the fact, that I have on more than one occasion confounded individual examples of these bodies with cells, which I afterwards found were derived from the cork of the bottles in which the urine, or some of my re-agents, were kept; and their general resemblance to various other organic, and especially vegetable cells, is such as might easily lead to mistakes on a cursory examination. On the other hand, their differences, from all the more ordinary forms seen in fresh urinary sediments, was sufficiently characteristic; and, under these circumstances, I confess that I have, on several occasions, passed them over rather hastily, from the conviction that, whatever their nature, they were of slight pathological significance, and had probably been introduced into the urine in some way or other from without, or been generated in it after its exposure to atmospheric influences.

I may observe that Dr. Spencer Thomson, of Haunton, has described and figured with great care bodies bearing considerable resemblance to those I have seen, and which appeared to him to multiply and re-produce themselves in a urine which had stood for some days after being passed. (See *Monthly Journal of Medical Sciences*, April, 1848.) The tendency of Dr. Thomson's observations is to show the fungoid, or confervoid character of these bodies. He observed them to crack and split up in a very peculiar manner, and believed them to contain the smaller sporules so frequently seen and above described. This latter peculiarity has not appeared to me to be perfectly made out in those I had an opportunity of seeing.

In the examination of the tissues of the human body, I have occasionally seen bodies more or less resembling the "cholera" fungi; but I can only recollect one instance in which the cells appeared to me identical with the annular bodies figured by Dr. Brittan. This was in a case of condensation of the upper lobes of both lungs, in which the diseased portions removed for examination were found to contain immense numbers of these bodies, amidst granular corpuscles and the usual pathological elements of pulmonary hepatization.

The occurrence of sporules and confervoid vegetations in effete or imperfectly organised animal matter, when exposed to decomposing influences, is so well known to every microscopic observer as to excite no surprise. Least of all should the presence of such bodies *in the stools* be supposed to demand a special explanation, until it is shown that none of those mixed matters which form the food and pass into the dejections in every stage of decomposition, contain or are capable of generating, similar organisms. The examination into this possible source of fallacy becomes the more necessary from the discovery, by my friend Dr. Jenner, of similar bodies in the stools of typhoid fever; thus placing it beyond all doubt, that cholera is not the only pathological condition in which they occur.

In some observations, published in July last, on the "Pathological Anatomy of Cholera," —(see *Monthly Journal of Medical Science*, July, 1849,)—I must confess having overlooked these peculiar productions in the cholera dejections. But in the comparatively few observations which I made on the cholera stools, passed during life, my object was to discover their essential, and, as it were, *basic* constituent; and, accordingly, everything which looked like foreign, or incidental matter, was at once passed over without remark. I am confident, however, that these bodies did not form a very prominent ingredient in the specimens I examined; and it is, indeed, evident, from Messrs. Brittan and Swayne's papers, that they are, in many cases, only to be found by searching for them, and in some cases not at all. The same remark applies to the constituents of urinary deposits found by Mr. Swaine in cholera evacuations,—viz., lithate of ammoniate, lithic acid, and oxalate of lime, none of which were observed by me in the specimens which I had an opportunity of examining. Triple phosphate was, indeed, occasionally found; but this salt, as is known to most microscopical observers, is frequently generated in decomposing animal fluids, and is by no means peculiar to the urine. In other respects, my observations on this subject correspond with those of Mr. Swayne.

In conclusion, I think it is sufficiently plain, that the inferences drawn from the discovery of the alleged cholera fungi were premature. It is not improbable, however, that the careful observation of the circumstances under which these remarkable bodies occur, may lead to some result of scientific interest, to which Messrs. Brittan and Swayne may justly claim to have led the way. I would willingly hope, that these desultory remarks may not be altogether useless in this investigation.

I am, Sir, your obedient servant,

W. T. GAIRDNER, M.D.,
Pathologist to the Royal Infirmary of Edinburgh.

London, October 19, 1849.

DR. W. R. CLANNY ON CHOLERA.

[To the Editor of the Medical Times.]

SIR,—I take leave to offer a few observations in respect to the epidemic and endemic nature of the cholera.

From the first appearance of the pestilence in this town to the present time, I am firmly impressed, that, upon its first appearance, whether in towns or in villages, it uniformly appeared to be of an epidemic character; but, in process of time, from innumerable cases, I am satisfied that it generally showed an endemic type, especially from emanations from the dead. It may not, perhaps, be too much to request you, Sir, to reprint a few paragraphs from my work on cholera published in 1832, which is now, I believe, nearly out of print:—

"At the workhouse, at that time, there were near 140 inmates, fifteen of whom died of epidemic cholera, including the sister-in-law and, afterwards, the master of the workhouse himself. This person had been for many months, from every appearance, obnoxious to apoplexy; and, as I had known him from his boyhood up, I warned him on this point at different times previous to his attack of cholera. I understand, from his professional attendant, that his was the epidemic cholera of rapid type, or "la cholera foudroyante" of French authors.

"As, in such cases, the patient seldom lived more than twelve or fourteen hours after the attack, the relations and friends of the patients, being astonished at the new phenomenon, were too apt to crowd round the sufferers, and many of them had reason to rue their temerity. But it was whilst performing the last sad offices for the dead, that contagion showed its greatest force, and such cases in this town were astonishingly numerous, so much so, that it is quite unnecessary to particularise them. Such of the faculty of this town as believed that we had epidemic or spasmodic cholera amongst us, will bear me out in this remark.

"At an early stage of our visitation, in consequence of information kindly furnished me by Lieut.-Colonel Rowles, E.I.S., I put the clergymen, and others who were likely to be near the dead, upon their guard, and showed the impropriety of taking the bodies

of cholera patients into our churches, in the performance of funeral service; and carriage by ropes from the hand, or by suitable conveyances, were strenuously recommended, and I hope, as often as could be, were put into practice. In these arrangements the Board of Health showed much anxiety. Many medical men of Sunderland are impressed that our first attack of epidemic cholera was directly owing to atmospheric distemperature; but how or when that state of atmosphere commenced, no man can say. It appeared to me that we all felt this atmospherical influence one way or other."

"I communicated Colonel Rowles' letter to the Government, and soon afterwards they issued a stringent order for early interment of the bodies of fatal cases of cholera throughout the empire, which has not been rescinded up to the present time.

"I have just received the enclosed Report from my friend, the Rev. A. Bethune, incumbent of Seaham Harbour, and J. P., which appears to me to be exceedingly interesting, as it shows the direct endemic character of the cholera.

Date of Illness.	Name.	Result.	Remarks.
Oct. 4	— Cowell (trimmer)	Died Oct. 4	A man of regular habits; felt poorly for some days before.
5	Mrs. Harrison	Died Oct. 5	Nursed Cowall and washed his clothes.
5	Mrs. Goodwill	Died Oct. 6	Daughter of Cowell; pregnant.
5	Mr. Goodwill (butcher)	Recovered	Husband of last.
6	Margaret Henderson	Died Oct. 6	Friend and neighbour of Mrs. Goodwill, an much with her; a healthy ung woman.
6	——, a joiner	Recovered	Measured and [illegible] Cowell.
6	Mr. Bailey	Recovered	Visited Cowell in his sickness.
6	Mrs. Bailey	Recovered	Ditto ditto
6	Mrs. Richard Pendlington	Recovered	Attended Cowell in his illness.
7	Quilter (a child)	Died Oct. 9	Living in the same house with the Goodwills.
7	Mrs. Henderson	Recovered	Mother of Margaret Henderson.
7	Margaret Fairles	Recovered	Attended Mrs. Goodwill.
9	Kinross (young girl)	Recovered	Attended Margaret Henderson.
7	Ann Davison	Recovered	Also attended Margaret Henderson.

For three weeks before Cowell's case, there had been no case of cholera at Seaham Harbour, and there has been no case since in Kinross. The above were the only cases at the time in the place.

Oct. 23. A. B.

I will not now enter further upon the subject, in the hope that you, Sir, or some of your numerous readers, may be induced to prosecute this interesting subject.

I remain, Sir, your obedient humble servant,
W. Reid Clanny.

Bishopwearmouth, 23rd Oct., 1849.

DR. DINGHAM ON CHOLERA AND ITS TREATMENT.

[To the Editor of the Medical Times.]

Sir,—The object of the present communication is not to swell the long list of remedies and plans of treatment proposed for cholera, but rather, in as condensed a manner as possible, to give the results afforded by the different methods I have pursued in those cases which have fallen under my notice.

First, then, I would observe, that during the epidemic which has so fearfully visited this place, I have seen three distinct forms, or, rather, three different degrees of malignity or virulence, marking the first onset of disease, and thus early determining the probable course and termination of the case.

The disease, in the first form, is ushered in by no premonitory symptoms. The patient is suddenly seized (having been previously in sound health), it may be with sickness, cramps, or pain in the abdomen. The bowels are emptied of their contents, so to speak, with a gush; a copious serous dejection soon follows, to which collapse immediately succeeds. For such a case as this, art is without remedy, and medicine useless; nor, indeed, is it to be expected that the advance of science will furnish us with any resource capable of combating with a malady so frightfully rapid in its progress, and producing such intense and sudden prostration. Persons thus attacked are hopeless from the moment of the first seizure.

In the second form there is bilious diarrhœa of longer or shorter duration, passing on into rice-water dejections, cramps, and vomiting, suppressed secretions, and the usual symptoms of cholera. But the nervous and vascular depression is neither so sudden nor pronounced as in the former instance. The skin, although reduced in temperature, still retains somewhat of its natural warmth and appearance; the discharges from the bowels, although often involuntary, are not copious, and collapse is more distant and tardy in its approach.

In the third form, the advance of this disease is much slower. Simple diarrhœa continues, it may be, a week or longer, before cholera symptoms show themselves. The close observer, however, will detect the difference between this and the usual autumnal diarrhœa. He will find it yield to the ordinary remedies less readily; is not attended with diseased secretions or injesta; the appetite is generally good, and slight irregular spasmodic pains are often complained of. This form of attack, if properly treated, seldom runs into collapse, and may be more correctly called "choleroid diarrhœa."

The treatment I have adopted has been different, according to the stage of the disease, and also experimental, to determine, as far as I could, the value of different plans. In the third, or last form I have described, when the diarrhœa continues for a long time, where the chalk mixture with opium failed, which it sometimes did, I always found the acetate of lead, given in the form of pill (3 gr.) every hour or every second hour, effectually check the disease. A strong astringent appears to be the great requisite here; and the only objection to the acetate of lead is, that the stomach will sometimes not tolerate it. But, by persevering in the remedy, combining it with opium, and occasionally administering stimulants in small quantities, together with counter irritation over the abdomen, and rigid adherence to the recumbent posture, I have always found the symptoms gradually give way, and the patient recover.

In the second and more aggravated form, the greatest difficulty I have experienced has been to get anything to remain on the stomach. Influenced by the popularity of Dr. Stevens' saline treatment, I gave an early trial to his chlorate of potass and soda powders, with the hot saline bath. Out of four cases treated this way, we were obliged to discontinue the remedy in two, on account of the intense sickness it produced. The powders were not retained a moment, and at last they were abandoned, as no benefit was likely to result from a medicine which was expelled as fast as it was taken.

In two of the cases they were persevered in throughout: both terminated fatally.

In ten cases, one-grain doses of calomel were given every half-hour;—out of these, three recoveries. It must be acknowledged, that some of them were not seen till collapse had actually taken place, so that this loose statement must not be taken as a fair trial of the remedy. To say truth, I had not much faith in the mysterious action of small doses of mercury, notwithstanding the high authority in its favour. Acetate of lead here, as in the former instance, only in larger doses, (5 grains every hour,) has proved most beneficial. It appeared to check the rice-water dejections and tendency to collapse in the bulk of those cases in which I used it. Frequently, however, it failed. Never, in any example, did I see any benefit arise from it when given to collapsed persons; it rather increased their sickness and misery. Its great value is most evident when given at the commencement of a case, and steadily persevered in throughout. No danger need be apprehended from its use. I have known one patient take as much as 70 grains in the day, and have it also administered in the form of enema, by which means the disease was eventually got under. Creasote and effervescing mixtures, sometimes relieved and sometimes aggravated the sickness. As for the former, if it did not at once improve the symptoms, it was quite useless to persevere with it. Cold water I always allowed, and it was truly surprising the quantity some persons swallowed.

Out of 30 persons in a state of collapse, I bled, or attempted to bleed, 12, and my friend Mr. Allen, who has been far more successful than myself, has bled a still larger number, and informs me that he has had five cases of recovery from decided collapse follow from an early and full bleeding.

In my own cases, some of them were seen for the first time after being either neglected or quacked; others had been under treatment before; all of them were cold, blue, pulseless, more or less cramped, with a whispering voice, suppressed secretions, involuntary discharges of serous fluid, vomiting, and great thirst. This condition, of course, varied in intensity; in some it was more advanced than in others. The above description, however, applies pretty accurately to them all. Two of the twelve on whom venesection was performed recovered. These are the only examples of recovery that I have seen from the collapse of cholera. In many instances, however, marked relief followed blood-letting; the vomiting was sometimes relieved, and the cramps always; and the labouring action of the heart, which was my guide as to when bleeding was requisite, became more tranquil. The patients themselves always expressed themselves relieved. Sometimes it is a very difficult matter to get blood to flow; but, by making a large orifice, and squeezing out the thick, tarry fluid for a little time, it eventually comes pretty freely. I have found, that removing the bandage from above the orifice occasionally facilitated the bleeding.

Already this Article has been extended beyond the limit I at first proposed to myself. I will conclude by stating, that I shall be happy to furnish any gentleman with the particulars of such cases as he may require.

I am, &c.,
John Dingham, M.D.

Gainsboro' Sept. 29, 1849.

LETTER FROM DR. BASCOME ON DR. COPLAND'S VIEWS OF CHOLERA.

[To the Editor of the Medical Times.]

Sir,—However much I may respect the erudition and laborious research of Dr. Copland, especially exemplified in his "Dictionary of Practical Medicine," I cannot let pass without notice the dogmatical opinions propounded by him, not only in his Dictionary, but repeated in a letter published in the *Medical Gazette* of 28th ult., to the effect that pestilential cholera is a disease, *sui generis*, and that it is contagious.

In his letter the Doctor observes, whatever "*twattle* may appear on the subject of non-contagion, of non-infection," &c. &c., and very pompously concludes, "that pestilential cholera will some day—(when?)—be acknowledged to be what I (*ego*) have long ago, and again more recently, *endeavoured* to show it to be, according to the most irrefragable evidence," &c. &c.

Now, with due deference to Dr. Copland, I, who have practised professionally for more than twenty years amongst the most deadly epidemics, endemics, &c. &c., viz., cholera, yellow fever, &c. &c., take leave to differ with him as to cholera or yellow fever, as stated in his Dictionary, being a malady, *sui generis*, or contagious; and in this opinion I am not singular, inasmuch as I am fully borne out by the *practical* experience of very many talented men who have, I may with safety venture to say, seen very much more of both diseases than himself, and whose acumen and general knowledge of disease would not be found wanting, should their *twattle* on the subject of non-contagion, &c., as also their opinion as to pestilential cholera not being a disease, *sui generis*, be tested with Dr. Copland's erudition, I defy it to be shown by any but the most negative evidence or proof, as it is called, that cholera is a malady, *sui generis*, or that it has ever been propagated, as Dr. Copland should state in his letter, "by a specific infectious emanation, *proceeding from* the sick," and which the Doctor says he has *endeavoured* to show by the most irrefragable evidence.

That the Doctor has endeavoured to show I freely admit; but that he has *shown*, I deny. That Dr. Copland's opinion is entitled to respect no one feels more than I,—also that it is worth a certain amount, but no more. Yet, when he so dogmatically propounds, in a medical periodical, doctrines on a subject of which there is an immensity yet to be searched after and learnt; and when propounding such doctrines sneeringly designates the opinions of medical men of very far greater practical experience than himself, twattle, he must be reminded that he is not infallible in a science which is scarcely recognized by many as such, so very imperfect are its principles, and that the opinions of others are entitled to quite as much respect, and are considered quite as valuable as his.

I am, Sir, your obedient Servant,
Edward Bascome, M.D.

October 10, 1849.

DR. W. L. RICHARDSON ON THE SALINE TREATMENT OF CHOLERA.

[To the Editor of the Medical Times.]

Sir,—In my last communication on Pestilential Cholera, I laid before you the unhappy result of a treatment by repeated small doses of calomel; one claiming many adherents, and which was said, in the

hands of some, to be fraught with incalculable benefit to a community suffering presently from the arm of the Angel of Death.

My object in again troubling you is to record five cases, treated on the saline plan of Dr. Stevens, one even more highly lauded than the former. As it is not my intention at present to theorize, I shall not enter upon the views of the upholders of either system, considering that to one surrounded by the dying and the dead, speculation gives place to facts, death proving many a syllogism to be incorrect in its major premise.

Many may, and have, I doubt not, charged me with carelessness of human life, in continuing, as I did, the calomel treatment through eighteen cases, one only of which survives, presenting a sore mouth and the loss of a few teeth. In the present instance, therefore, I discontinued this treatment, after having satisfied myself of its total inutility in four cases out of five. In these, as in the former, I endeavoured to avoid laying myself open to any charge of having deviated from the practice of the originator; and have adhered strictly to the formulæ given in the *Medical Times* of September 1st.

No.	Age	Sex	STATE ON ADMISSION. Temperature reduced, Voice and Expression altered; Pulse small and frequent. Collapsing.	Temperature much reduced; Lividity; Voice Choleraic; Pulse Indistinct—very small. Partial Collapse.	Temperature very much reduced; no Pulse at wrist; more or less Insensible. Complete Collapse.	Amount of Salines Administered.	Lived after Admission.	Passed into Re-action, when.	Made Water, when.	Died in Collapse.	Died in Consecutive Fever.	Recovered.
1	28	M	1	......	......	Sodii. Chlorid. ℥vii. Potass. Chlorat. ʒiii. Sodæ sesquicarb. ʒiiss. Enema also.	7 hours	...	...	1	...	...
2	40	F.	......	......	2	Sodii. Chlorid. ℥v. Potass. Chlorat. ʒii. Sodæ sesquicarb. ʒi. ℈ii. Enema also.	4½ hours	...	...	1	...	...
3	32	F.	3	......	......	Sodii. Chlorid. ℥vii. Potass. Chlorat. ʒiii. Sodæ sesquicarb. ʒvi.	9 hours	...	...	1	...	...
4	48	M.	4	......	......	Sodii. Chlorid. ℥viii. Potass. Chlorat. ʒv. Sodæ sesquicarb. ℥iiss.	...	in 10 hours	30 hours after admission	...	...	1
5	45	F	......	5	......	Sodii. Chlorid. ℥viii. Potass. Chlora. ʒiiss. Sodæ sesquicarb. ʒviiss.	27 hours	...	...	1	...	...

These cases present really little of interest beyond the mere fact of the absence of any curative effect in four. I may state that I found it a matter of some difficulty to induce the patients to take the saline mixture; but pressed such upon them so long as they possessed the ability to swallow,—cheating them and myself with hopes of their recovery. Private Practitioners may thus, I doubt not, be deterred from giving what they consider a fair trial to this plan; and owing, in some measure, to this, I have met with many whose views were not conclusive on the present treatment.

And now, Sir, the question naturally presents itself to every reasoning mind, whence the discrepancy between these reports, and those issuing from London and Hull? Such can, I think, rest on one of three points only.

1st. The mis-statement of facts.

2ndly. The non-agreement of the remedies, either in quality or quantity.

3rdly. The non-agreement of the terms expressive of the disease.

I cannot, for one moment, allow the first of these a consideration, in reference to the cases brought forward by the advocates of the respective systems; nor can I charge myself with any want of candour; this, therefore, falls to the ground.

As regards the second, all chances of probabilities are in favour of the analogy of the drugs in point of quality, and my own senses' evidence of the quantity administered; this, therefore, also falls to the ground.

The third point becomes thus the only one tenable,—namely, the non-agreement of the terms expressive of the disease.

It may be a peculiarity, and one hitherto unobserved, of this malady, that its features differ in localities separated, not by climates, but by counties; that while we expect quinine to act as a specific in intermittent fever, whether administered at London, Hull, or Edinburgh, calomel and salines exert their dominion over cholera in limited spots only. This, however, to say the least, is not probable, and I am forced, therefore, to the conclusion, that our reports have been drawn from cases not strictly in unison, as regards the disease at issue.

I am, Sir, your obedient servant,

W. LINDESAY RICHARDSON, M.D.

Edinburgh Cholera Hospital,

Sept. 23, 1849.

DR. CONOLLY AND THE COMMISSIONERS IN LUNACY *versus* THE LORD CHIEF BARON, TOUCHING THE CASE OF NOTTIDGE *versus* RIPLEY.

" Audi alteram partem."—Virgil.

[To the Editor of the Medical Times.]

SIR,—In an able leading Article, contained in the *Medical Times* of September 22, 1849, you have made some very pungent remarks relative to the working of the existing law of Lunacy, and the official conduct of the Lunacy Commissioners.

As the treatment of insane persons, and the management of lunatic hospitals has occupied a large share of my time and attention, during the last ten years, I trust you will, on the *audi alteram partem* principle, allow me to offer a few practical observations thereupon.

Before doing so, however, I think it right to state, that I am a perfectly disinterested party in the present matter, not being officially connected with any lunatic establishment, public or private. This preliminary statement appears the more necessary, as I find that an attempt has been made to place my learned friend, Dr. Conolly, *hors de combat*, on the plea of his being the proprietor of " a private lunatic establishment." Dr. Conolly is quite competent to break a lance with any champion who may enter the lists against him; nevertheless, I cannot help expressing my conviction, that his late admirable " Remonstrance with the Lord Chief Baron" was dictated by feelings of the purest philanthropy, and not from any sordid considerations of " filthy lucre." Dr. Conolly, by means of his invaluable clinical lectures on Insanity, and his able advocacy, (both by precept and example,) of " the humane system of non-restraint," has established for himself a more than European reputation, and may his life be long spared to reap the fruits of his arduous exertions. Let us, however, proceed to the points at issue. In the course of a late trial " Nottidge *v.* Ripley," (of which there is an excellent report in the eighth Number of Dr. Forbes Winslow's *Psychological Journal,*) the Lord Chief Baron is reported to have given utterance to the following dicta :—" It is my opinion that you ought to liberate every person who is not dangerous to himself or to others. If the notion has got abroad, that any person may be confined in a lunatic asylum or a madhouse, who has any absurd, or even mad opinion, upon any religious subject, and is safe and harmless upon every other topic, I altogether and entirely differ with such an opinion, and I desire to impress that opinion, with as much force as I can, in the hearing of one of the Commissioners. Now, with all due deference to the legal wisdom of the learned Chief Baron, I can scarcely conceive a more mischievous or dangerous doctrine, (whether as regards the welfare of the insane themselves, or the comfort and security of society,) to have emanated from the lips of mortal man. How much more, then, is the evil enhanced as issuing from such high official authority? What would be the consequences of carrying out this *ex-cathedrâ* doctrine of the learned Chief Baron." Thousands of lunatics, " not dangerous to themselves or to others," but yet a prey to the wildest delusions, and most horrible hallucinations, would, at " one fell swoop," be cast loose upon the vortex of society! Bedlam would, indeed, be let loose, as Dr. Conolly has truly remarked! And what physician, surgeon, or barrister, very learned in the law, (for these gentlemen would lay claim to a knowledge of all the intricate phenomena of mental derangement,) however versed in psychological studies, shall tell us, when persons labouring under mental illusions are dangerous, and when the reverse? How many frightful domestic tragedies are revealed to us through the columns of the weekly Press, where persons, driven on by some sudden and irresistible impulse, or ordered by some imaginary voice, have murdered their nearest and dearest relatives in cold blood, and afterwards terminated their own existence? Will such tragedies be diminished, or rather, will they not be increased tenfold, supposing the absurd dogma of the Chief Baron to be put in execution? The public Press, and other parties who have thought fit to laud the *seeming humanity* of the Lord Chief Baron, *know practically nothing of the real merits of the case.* Let them divest themselves of their prejudices, and visit the wards of some of our public lunatic hospitals, such as Lincoln, Northampton, Lancaster, Hanwell, &c., and the intelligent medical superintendents of those noble establishments would speedily furnish them ocular demonstration of insane persons, who, though " not dangerous to themselves or to others," still require, for their own safeguard, the healthy discipline and moderate control of a well-conducted hospital. Many of those parties who have joined in the senseless clamour against the Medical Profession, and their interference with the insane, know no more about the phenomena of mental derangement than the Pope of Rome. The Commissioners, in their lucid and well-digested letter to the Lord Chancellor, have endeavoured to place the matter in its proper light: they remark,—" The object of these acts is not, as your Lordship is aware, so much to confine lunatics, as to restore to a healthy state of mind such of them as are curable, and to afford comfort and protection to the rest. Amongst the many persons confined as being lunatics, or of unsound mind, those who are manifestly dangerous; that is to say, those who, by some overt act, have already proved themselves to be dangerous, are, comparatively, few in number; the far more numerous class consisting of, 1. Those who are sent into lunatic establishments for the purpose of treatment, with a view to the alleviation and cure of their malady; 2. those who, from disease of mind, are incapable of self-government, and who, therefore, require, at certain periods, (or, perhaps, generally,) the most careful supervision and control; and 3, those who are incapable of taking care of themselves or their affairs, and are likely, therefore, to sustain serious injury if left at large and unprotected. It may reasonably be asked, what would become of all these large classes of the insane, if set at large, in conformity with the Lord Chief Baron's opinion?" There appears to be an attempt now making to instil into the public mind a most unfounded prejudice against the Medical Profession, as regards their interference with the insane; the public Press appears to have got hold of the delusion, that medical men wish to exercise a despotic control over the liberty of the subject; this, I need not remark, is a great and grievous error. If lunatics are not isolated from their friends and the public, how is the medical

treatment, necessary for the cure of their malady, to be carried on? Mental derangement, in this respect, differs from all other disorders with which I am acquainted, namely, that it cannot be effectually treated unless the patient be removed from home. That medical men are not disposed to tyrannize over the insane, I may merely point to the improved moral and physical condition of lunatics generally, since the Parliamentary inquiry in 1815, and which improvement I believe to be mainly owing to the unceasing and disinterested exertions of the Medical Profession. But to return to our subject:—As a proof of the dangerous effects resulting from the release of lunatics from the salutary control of asylum discipline, I shall take leave to quote the particulars of a case which happened, under my own observation, at Lincoln. W. C. H., a surgeon, who had been for several years confined in the Lincoln Lunatic Hospital, was sent home (after due notice to that effect), in consequence of his wife having become greatly in arrear of payment for his maintenance, &c. This patient had been under my observation for more than two years; but was not considered by me, or, I believe, any other Medical officer of the Establishment, as "dangerous to himself or to others." As a proof of which he was allowed considerable latitude about the house and grounds; and even occasionally assisted me in the Dispensary in compounding drugs, &c.; in fact, this patient, like many others, was very manageable whilst under asylum discipline; but no sooner did he arrive at home (Falkingham) than "a change came o'er the spirit of his dreams." In the house occupied by his wife, there lodged a clergyman; the maniac, now left to indulge his "wayward fancies" uncontrolled, speedily got hold of the delusion, that the reverend gentleman had some improper connexion with his wife, (there was, so far as I could learn, not the slightest ground for such belief;) and, goaded to frenzy by the thought, he procured a double-barrelled gun, and would probably have put an end to the clergyman's life, but for the assistance of several constables; and, after a violent struggle, he was overpowered by numbers, and placed in the Falkingham Gaol, as the only place of safe detention, until measures could be taken for his removal to the Asylum. I should mention, also, that, from his great agility and feats of prowess on the persons of the turnkeys, that they magnified (such is often the case with respect to lunatics) his real powers, and put him in irons for further security. In my capacity of House-Surgeon to the Lincoln Asylum, I received this man on his re-admission, and shall not readily forget the extreme unction with which he related to the attendants and myself "the way in which he had drubbed the turnkeys, and how frightened they were of him, until they had got him chained up." He settled down very quietly with us, nor did we even find it necessary to place him in the refractory ward. So true it is, that lunatics, seeing an overpowering force of practised attendants about them seldom attempt violence; this is the grand secret in all Lunatic Hospital management. My esteemed friend, Dr. Conolly, in his able Remonstrance with the Lord Chief Baron," has so forcibly exhibited the reasons why certain lunatics, "not dangerous to themselves or to others," are still unfit to be at large, that I shall offer no observations upon that subject, further than to express my entire accordance with the views which he has there so clearly expounded, and to which no one (either of the legal fraternity, or the public press) has yet ventured a reply.

I shall now, Mr. Editor, take leave to comment upon some of your own observations, in the article before alluded to. First, "We have reason to believe that the Medical Profession and the public are equally dissatisfied with the administration of the existing law of lunacy, which does not appear to provide any adequate protection for the liberty of the subject when accused of being insane; and which does not afford any guarantee that persons who, unhappily, are so afflicted, and whom it may be necessary to place in confinement, shall be treated with kindness and humanity." Now, Sir, with regard to the Medical Profession not being satisfied with the working of the present law of lunacy, I must beg to observe that the great mass of the Profession (always excepting those officially connected with public or private lunatic establishments) know literally nothing concerning the proper treatment of insane persons. I say this advisedly—as the result of my own observation; and deeply regret that it should be so: my own case was precisely similar on being appointed to the Lincoln Asylum in April, 1840. Moreover, this evil is not likely to be materially abated until Government steps forward and peremptorily throws open the wards of every public lunatic hospital in the kingdom, for the purposes of clinical instruction; and further demands that every person hereafter entering the portals of the Medical Profession (be he Physician, Surgeon, or Apothecary) shall be carefully examined (by competent judges) as to his practical acquaintance with the phenomena and treatment of mental disorders. This is the only real and effectual remedy for our present grievances. What signifies making new laws on lunacy, when nine-tenths of the Medical Profession know not how to treat the disease when they see it? We have, now, probably, 10,000 incurable lunatics in England and Wales. Would a fresh law of lunacy restore the natural functions of a brain reduced (by neglect or improper depletive remedies) to absolute fatuity? Let our efforts be directed against the *fons et origo mali*, and not against the remote effects of the malady. I make serious objection to your phrase "accused of being insane." Insanity is not a crime or a disgrace, but a heavy dispensation of Providence; many persons so afflicted have not brought on the malady by any misconduct of their own, and this especially applies to hereditary insanity. In days gone by, it was, unfortunately, too much the practice to view this malady as a stigma, leprosy, or plague-spot; but thanks to the able advocacy of and Christian principles inculcated by many learned physicians relative to the true nature of insanity, such bigoted and superstitious views (worthy only of the dark ages) are now rapidly clearing away, and the mists of prejudice and intolerance are yielding to the bright rays of Christian benevolence and humanity.

To this supposed disgrace attaching to any family who may, unhappily, have a member afflicted with mental derangement, I attribute, in a great measure much of the cruelty, neglect, and privation, which have been visited upon the insane. Dr. W. F. A. Browne, one of our most enlightened and experienced Physicians in this department of medical science, has drawn a very forcible and faithful picture of this popular failing in the Seventh Annual Report of the Crichton Royal Institution for Lunatics, pp. 7 and 8:—"The confession is humiliating to our common nature; but it is necessary that it should be known that mental disease is regarded by the ignorant, and by many who are not so, with loathing and abhorrence, and leads to disruption and oblivion of the ties by which man and man, the strong and weak are, or ought to be, bound together. It will be found that this affection often establishes a barrier between those most intimately united by blood, or interest, or feeling; dissolves the contract of duty, affection, and honour; and consigns the sufferer to exile from those immunities and advantages of his position, which would contribute to comfort, and might lead to cure within a short period. I have seen a lunatic, who, bound and galled, and cut by his bonds, had been crushed and confined in a small hole beneath a stair, where, although deprived of every means to inflict injury, and dependent upon those who had shorn him of his former powers and privileges, he was shunned by his relatives, as the plague-stricken were formerly shunned. It is known that lunatics are immured in cellars, closets, and lofts; that they are allowed to wander nearly nude in the pitiless storm that they are ill fed, neglected, and cast out."

Doubtless, abuses still continue to exist in many lunatic establishments; but I am inclined to think, as the result of my own observation, in the treatment of insane persons in several counties of England, that were a balance-sheet strictly drawn between the management of patients in public hospitals, and that pursued in private establishments, and towards those in the custody of their own friends and relatives, a great preponderance of abuse, cruelty, and privation would be found on the side of the two classes last named; and, moreover, I will give a very powerful reason why such should be the fact. In our large well conducted public hospitals for the insane, the governing bodies, and the medical staff, feel a laudable pride in the admirable order, cleanliness, and contented appearance which (even to a casual observer) pervade their establishments and their patients, and, consequently, they freely court the public eye and public opinion; they take an absolute pleasure in showing that everything belonging to their patients, their grounds, their airing courts, domestic offices, &c., is at all times in order for review." This is a noble ambition, deserving of encouragement, and has tended (in the absence of higher feelings) greatly to ameliorate the moral and physical condition of the insane. But turn to the private asylums, and where do you find the freedom of inspection there? They are (to use your own emphatic and truthful remarks) hermetically sealed against the admission of visiters and friends. I speak confidently on this matter, having been refused admission to several private lunatic establishments. The Governors of the Lincoln Asylum, in their Fifth Annual Report, remark: "It may, indeed, be laid down as a principle in human nature, which experience will amply confirm, that no Institution of this sort can be considered safe in its management where the Managers are not subject to some eye unconnected with the government of the Institution itself. The public eye and public opinion have, in all cases, been found the most efficient; and the original rules of this Institution, wisely and humanely acting upon this principle, court and avow a system of public inspection under due regulation." Now, the principle here laid down, cannot be too extensively promulgated. No one, that I am aware of, has ever attempted to dispute its soundness, as applied to public Lunatic Hospitals; but, persons will tell you, that the principle cannot be applied to private establishments! Why not, let me ask? Are the inmates of the latter less liable to abuse, cruelty, and privation, than those of public Institutions? By no means; human nature is the same everywhere; brute keepers and indolent officers, who neglect their principal duty. Careful supervision of the patients and the demeanour of the attendants towards them, will be found, I fear, in both public and private establishments. Dr. Charlesworth, of Lincoln, has truly remarked: "From the peculiar nature of an asylum for the insane, the most horrible abuses may exist within its walls without suspicion, and almost without the possibility of detection. Sir Andrew Halliday has observed: 'The mystery which has been made to hover round the precincts of a mad-house, was sufficient to baffle common inquiry; and the utter seclusion, so insidiously inculcated, made it next to impossible to discover the scenes of horror that took place within its walls.' Hence our attention should ever be directed to a system of prevention, which can be rendered effectual only by keeping our grounds, courts, galleries, cells, offices, and, as much as possible, the persons of the patients, open to that rational inspection which our rules have provided for, and which general experience has shown to be safe as well as necessary." Will any person, who knows anything of lunatic management pretend to tell me, that the infamous neglect and abuse which characterised the whole management of the Haydock Lodge Asylum would have continued so long, if the public eye and public opinion could have had free access to its wards? Mr. Graham (then House-Surgeon of the Lincoln Asylum) and myself, both men officially connected with lunatic management, were refused admission, when we desired to observe the apartments occupied by private patients! My own opinion is, and it results from extensive observation, that this systematic exclusion of the public eye is one of the greatest evils to be found in private lunatic establishments. The Governors of the Lincoln Asylum, in their Fourteenth Annual Report, pages 6 and 7, have truly remarked: "The popular belief in the ungovernable ferocity of the insane, encouraged by persons more studious of their own ease and enjoyment than that of the patients entrusted to their care, has been very mischievous, and has tended to excuse restraints and other severities, on the assumption of their necessity; whereas, in truth, it is this very practice which renders the complaint intractable, and gives to it a character of exacerbation, seeming to justify both the prejudice and the treatment. Such prejudices and their consequences can only be corrected by opening examples of a milder management to the inspection of society, which has a deep personal concern in the mild or harsh treatment of a complaint which may affect any, either personally, or through relatives and friends.

Dr. Farre observes: "The words of the talented Samuel Tuke on this subject are golden: 'I believe that I am not too sanguine when I say, that for one evil arising from accidental visitation, ninety-nine will be prevented. The evils of visitation are speculative bugbears, to which practical men have too often found it convenient to give the character of reality.'"

There are several other points in the Article alluded to, which I should wish to remark upon; but the present paper having already reached an inconvenient length, I will, Mr. Editor, with your kind permission, discuss them in a future communication.

I am, Mr. Editor, yours very faithfully,

William Smith, Surgeon, &c.

Belper, South Derbyshire, Oct. 17, 1849.

[Upon the *audi alteram partem* principle, we have much pleasure in giving insertion to the above letter. Indeed, we are anxious to hear, no matter from what

quarter, whether anything can be advanced in defence of the present defective state of the Law of Lunacy. The subject is one which invites discussion, with a view to suggesting some plan for its alteration and amendment. We reserve, therefore, our observations on Mr. Smith's letter until we have time to throw out some suggestions for the amendment of the present state of the law and government of public and private Lunatic Asylums.—Ed. *Med. Times.*]

MEDICAL WITNESSES ACT.

"Whereas it is expedient to provide for the attendance of medical witnesses at Coroners' inquests, also remuneration for such attendance, and for the performance of *post-mortem* examinations at such inquests; be it therefore enacted, by the King's Most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, That from and after the passing of this Act, whenever, upon the summoning or holding of any Coroner's inquest, it shall appear to the Coroner that the deceased person was attended at his death, or during his last illness, by any legally-qualified Medical Practitioner, it shall be lawful for the Coroner to issue his order, *in the form marked (A) in the schedule hereunto annexed*, for the attendance of such practitioner as a witness at such inquest; and if it shall appear to the Coroner that the deceased person was not attended at or immediately before his death by any legally qualified medical practitioner, it shall be lawful for the Coroner to issue such order for the attendance of any legally qualified medical practitioner being at the time in actual practice in or near the place where the death has happened; and it shall be lawful for the Coroner, either in his order for the attendance of the medical witness, or at any time between the issuing of such order and the termination of the inquest, to direct the performance of a *post-mortem* examination, with or without an analysis of the contents of the stomach or intestines, by the medical witness or witnesses who may be summoned to attend at any inquest; provided that if any person shall state upon oath before the Coroner that in his or her belief the death of the deceased individual was caused partly or entirely by the improper or negligent treatment of any Medical Practitioner or other person, such Medical Practitioner or other person shall not be allowed to perform or assist at the *post-mortem* examination of the deceased.

"II. And be it further enacted, that whenever it shall appear to the greater number of the Jurymen sitting at any Coroner's inquest, that the cause of death has not been satisfactorily explained by the evidence of the Medical Practitioner or other witness or witnesses who may be examined in the first instance, such greater number of the Jurymen are hereby authorised and empowered to name to the Coroner in writing any other legally qualified Medical Practitioner or Practitioners, and to require the Coroner to issue his order, in the form herein-before mentioned, for the attendance of such last-mentioned Medical Practitioner or Practitioners as a witness or witnesses, and for the performance of a *post-mortem* examination, with or without an analysis of the contents of the stomach or intestines, whether such an examination has been performed before or not; and if the Coroner, having been thereunto required, shall refuse to issue such order, he shall be deemed guilty of a misdemeanour, and shall be punishable in like manner as if the same were a misdemeanour at Common Law.

"III. And be it further enacted, that, when any legally-qualified Medical Practitioner has attended upon any Coroner's inquest in obedience to any such order as aforesaid of the Coroner, the said Practitioner shall, for such attendance at any inquest in Great Britain, be entitled to receive such remuneration or fee as is mentioned in the Table marked (B) in the schedule hereunto annexed; and, for any inquest held in Ireland, the said Practitioner shall be paid in the manner provided by the laws in force in that part of the United Kingdom; and the Coroner is hereby required and commanded to make, according to the form marked (C) in the schedule hereunto annexed, his order for the payment of such remuneration or fee, when the inquest shall be held in Great Britain, and such order may be addressed and directed to the Churchwardens and overseers of the parish or place in which the death has happened; and such churchwardens and overseers, or any one of them, is and are hereby required and commanded to pay the sum of money mentioned in such order of the Coroner to the medical witness therein mentioned, out of the funds collected for the relief of the poor of the said place.

"IV. Provided nevertheless, and be it further enacted, that no order of payment shall be given, or fee or remuneration paid, to any Medical Practitioner for the performance of any *post-mortem* examination which may be instituted without the previous direction of the Coroner.

"V. Provided also, and be it further enacted, That when any inquest shall be holden on the body of any person who has died in any public Hospital or Infirmary, or in any building or place belonging thereto, or used for the reception of the patients thereof, or who has died in any County or other Lunatic Asylum, or in any public Infirmary or other public Medical Institution, whether the same be supported by endowments or by voluntary subscriptions, then and in such case nothing herein contained shall be construed to entitle the medical officer whose duty it may have been to attend the deceased person as a medical officer of such Institution as aforesaid to the fees or remuneration herein provided.

"VI. And be it further enacted, that where any order for the attendance of any Medical Practitioner, as aforesaid, shall have been personally served upon such Practitioner, or where any such order, not personally served, shall have been received by any Medical Practitioner in sufficient time for him to have obeyed such order, or where any such order has been served at the residence of any Medical Practitioner, and in every case where any Medical Practitioner has not obeyed such order, he shall, for such neglect or disobedience forfeit the sum of five pounds sterling, upon complaint thereof made by the Coroner or any two of the jury before any two justices having jurisdiction in the parish or place where the inquest under which the order issued was held, or in the parish where such Medical Practitioner resides; and such two justices are hereby required, upon such complaint, to proceed to the hearing and adjudication of such complaint, and, if such Medical Practitioner shall not show to the said Justices a good and sufficient cause for not having obeyed such order, to enforce the said penalty by distress and sale of the offender's goods, as they are empowered to proceed by any Act of Parliament for any other penalty or forfeiture.

"VII. And be it enacted, that nothing in this Act contained shall extend to Scotland.

"TABLE OF FEES.

"1. To every legally qualified Medical Practitioner for attending to give evidence under the provisions of this Act, at any Coroner's Inquest whereat no *post-mortem* examination has been made by such Practitioner, the fee or remuneration shall be one guinea.

"2. For the making of a *post-mortem* examination of the body of the deceased, either with or without an analysis of the contents of the stomach or intestines, and for attending to give evidence thereon, the fee or remuneration shall be two guineas."

QUEEN'S COLLEGE, CORK.

The matriculation examination will be held on Tuesday and Wednesday, the 30th and 31st of October, and the scholarship examination on Friday, Saturday, and Monday, the 2nd, 3rd, and 5th of November, 1849.

Supplemental matriculation examinations will be held on Tuesday, 13th November, 1849, and at the commencement of the Second Term of the Collegiate Session—viz., on Tuesday, 8th January, 1850.

The several departments of the College will open for public instruction on Wednesday, the 7th November, 1849.

President, Sir Robert Kane, F.R.S., M.R.I.A.; Vice-President, John Ryall, LL.D.

Faculty of Medicine.—Anatomy, Physiology, and Practical Anatomy.—Practice of Surgery, Dennis B. Bullen, M.D.; Practice of Medicine, D. O'Connor, M.D.; Materia Medica, A. Fleming, M.D.; Midwifery, J. A. Harvey, M.D.; Chemistry, J. Blyth, M.D.

Previous to being admitted to the matriculation examination in arts, each candidate will be required to pay to the bursar of the College the matriculation fee and a moiety of the class fees for the session, amounting together to 7*l*., which will be returned to the candidate in the event of his failing to pass the examination. Payment of the remaining moiety of the class fees for the session, amounting to 4*l*, will be required from the student before the end of the first term. Scholars will be exempted from this latter payment of 4*l*. The matriculation and class fees for the first year in the school of agriculture will be 7*l*. 10*s*. for students, and 4*l*. 10*s*. for scholars.

The lectures of the several Professors will be open to persons not matriculated students, on payment of the regulated fees.

The Professor of Chemistry will be prepared to receive a limited number of working pupils into the laboratory, who will receive instruction in chemical manipulation and analysis.

QUEEN'S COLLEGE, GALWAY.

[The regulations, scholarships, &c., are precisely similar in each College.]

President, Very Rev. J. W. Kirwan, D.D.; Vice-President, Edward Berwick, A.B.

Faculty of Medicine.—Anatomy and Physiology and Practical Anatomy, Croker King, M.D., M.R.I.A., F.R.C.S.I.; Practice of Surgery, James V. Browne, M.D.; Practice of Medicine, N. Colahan, M.D.; Materia Medica, Simon M'Coy, M.D.; Midwifery, Richard Doherty, M.D.; Chemistry, E. Ronalds, M.D.

MEDICAL NEWS.

Apothecaries' Hall.—Names of gentlemen who passed their Examination in the science and practice of medicine, and received certificates to practise, on Thursday, Oct. 18, 1849:—David Morgan, Llandilo, Carmarthenshire; Josiah Pritchard, Milbourne, Wilts; Hay Sharpley, Louth, Lincolnshire.

War Office.—26th Foot—Staff Surgeon of the Second Class Andrew Ferguson, M.D., to be Surgeon, vice Heise, who resigns. 58th Foot—Assistant Surgeon Alexander George Montgomery, from the Staff, to be Assistant Surgeon, vice Bannatine promoted on the Staff. Hospital Staff.—Assistant Surgeon Richard Bannatine, from the 58th Foot, to be Staff Surgeon of the Second Class, vice Ferguson appointed to the 26th Foot.—Acting Assistant Surgeon Edward James Franklyn, to be Assistant Surgeon to the Forces, vice Montgomery, appointed to the 58th Foot.

Royal College of Veterinary Surgeons.—The following gentlemen, having undergone the necessary examinations for the diploma before the Court of Examiners appointed under the charter, have this year been admitted members of the College:—Thomas Cade, Devon; William Lockhart, Glasgow; Edward Evanson Ashe, Cork; Charle, Edward Barton, Coventry; John Finlayson M'Gill Ayrshire; William Aitken, Edinburgh; Thomas Secker, Knaresborough; Charles Barker, William Stephenson Thornton, Yorkshire; Alexander Robinson, Greenock; John Roalfe Cox, London; Whitfield Smith, Liverpool; William East, Aylesbury; William Clark, London; Richard Stone Blake, Castle Carey; Edward Garton, Loughborough; Stephen Evershed, Richard Barker, Middlewich; Thomas John Williamson, London; Alfred John Shorten, Ipswich; John Gates, Prescot; Edward Simpson Shove, Sudbury; Thomas Johns, St. Pancras; Matthew Stone, Wentworth; James Wright, Burnham Overy; Jeffrey Dawtrey, Petworth; John Davis Barford, Gayhurst; Alexander Mayor, London; Robert Gibton, Charles Turner, Carshalton; Thomas Cunliffe, Blackburn; Richard Glengall Kelly, Borrisokane; John Magrath, Castlebellingham; John Humphreys Lane, Goulton; Joseph Sampson Gamge, St. Pancras; Forbes A. Hely, Hounslow; William Thomas O'Donnell, Henry Michael Hancock, Ealing; Joseph Lawrence, India; Thomas Turner, junior, Croydon; William Cooper, Berkhamstead; Thomas Swainson Griffiths, London; Henry W. Cannell, Liverpool; John Samuel Woods, London; Joseph Reeve, Outwell; William Wallace, jun., Wolverhampton; Thomas Daniel Willshire, Merthyr Tydvil.

Obituary.—On Tuesday, the 6th instant, aged 25, Ray Charles Golding, M.D., eldest surviving son of Dr. Golding.—On the 17th instant, at 3, Storey's-gate, St. James's-park, John Wright, M.D., aged 44.—On the 16th instant, at his house in Clonakilty, in his 59th year, William Ffolliott, Esq., M.D.

University of Cambridge.—The degree of M.B. was, last week, conferred on John Anthony,

of Caius College. At the same congregation, Dr. Bond, of Corpus Christi College, was appointed Examiner for Medical Degrees during the ensuing year. We think the University has, in this instance, made a most judicious selection, as Dr. Bond, by his talents and experience, is eminently qualified for the important situation he is called to fill.

SANITARY STATE OF THE CITY OF LONDON.—We are not surprised that Cholera has proved so fatal in the city, when we find that so many houses are in the condition described in the following Report from the Commissioner of Police:—

"The sergeants of the force, who were selected for this duty, reported upon the state of 15,010 houses in the following several respects:—

"12,878 houses were reported as generally clean in appearance, but in many instances were found, upon close examination, to require special notice for one or more of the following nuisances:—

"2132 required whitewashing or other cleansing, on account of general dirtiness.

"2524 had offensive smells, from bad drainage and other causes.

"720 had filth or rubbish in the cellar.

"106 had stagnant water on the premises.

"51 were found offensive, from the deficiency of dustbins, and the necessary accommodation for refuse.

"446 were found in an offensive and unhealthy state, from bad or deficient drainage.

"154 were found in much need of water, or used water deteriorated by improper receptacles.

"109 presented the necessity of having their dustbins immediately cleared.

"148 presented nuisances of various descriptions unfavourable to health, not previously described.

"13,020 houses had privies and water-closets free from nuisance.

"1120 had privies and water-closets in a very offensive state.

"4608 had their privies in the cellars.

"4389 had their privies in passages and other parts of the houses.

"4991 had their privies in yards and outer premises.

"152 privies were used in common by more than one house.

"223 cesspools were found full of soil.

"30 had burst, or had overflowed.

"21 cellars were used as cesspools.

"40 drains were found to be choked with soil.

"The above Reports have reference to the internal state of houses; the following is the nature of outdoor nuisances:—

"103 reports have been made by the police of stinks from the drains, gratings, &c.

"92 of stagnant water in the streets or out-door premises.

"16 of accumulated deposits of offal, decayed vegetable, or other offensive matter in yards, wharfs, &c.

"36 of unwholesome trades, manufactures, or other operations.

"28 of urinals, or places used as such by the public, in an offensive state.

"32 of dung and dust heaps offensive to their neighbourhoods.

"51 of common privies complained of as nuisances.

"8 of various nuisances not particularly defined.

"In addition to these representations upon internal and external circumstances, 952 cases of actual cholera have been ascertained through the information of the medical attendants, and reported in the daily returns, of which number 635 have proved fatal, 286 have recovered, and 31 are still under treatment, or the result is not ascertained, the sufferers having been removed to the country.

TESTIMONIAL TO DR. BROWNLESS.—A public meeting of the friends of Dr. Brownless, and subscribers to the Royal General Dispensary, Aldersgate-street, and the Metropolitan Dispensary, Fore-street, was held last night, at the Queen's Hotel, St. Martin's-le-Grand (Mr. William Pritchard, High Bailiff of Southwark, in the chair,) for the purpose of carrying into effect the intention announced at a previous meeting in the Aldersgate street Literary Institution, of presenting Dr. Brownless with a testimonial of their esteem upon the occasion of his resigning his position as resident physician to both the above dispensaries. Resolutions were passed, imbodying the sentiments of the meeting in regard to this gentleman, and appointing a Committee to receive subscriptions, and to decide on the form of a suitable testimonial, and otherwise to carry into effect the object of the meeting.

THE HENLEY-ON-THAMES WATER PLAN.—Though we do not profess to be learned in geology, or to be cunning in detecting errors in calculations and estimates,—we regard, with great interest, the proposed plan for uniting all the Metropolitan Water Companies under one common form of government, and thus relieving us from the extortions to which we are now exposed. Some may think it will be merely substituting one tyrant for many,—but be it so,—it is a preferable state. One benefit, at any rate, will have been conferred upon us by the late invasion of cholera, in the bestowal of greater attention to the comforts of the poor, and most particularly in supplying them with that essential requisite to health and cleanliness,—pure water. Apart from the question of practicability, the plan advocated by the supporters of the Artesian system of procuring water, has a manifest advantage over the Henley, or any other project, as being the only means of obtaining water in a state of purity. It is, however, worthy of consideration, whether or not some plan of purifying the present fluid, (which is certainly better employed as a fertilizer of vegetables, than as a potation for man,) cannot be devised, in order to render it available for domestic and culinary purposes—as it is, it is utterly unfit for such a use. The subject is one of the greatest importance,—it *demands* the attention of every one,—an alteration *must* be made; and if, as may be expected, a struggle be unavoidable, the motto of the banner, under which we contend, should be, "Frigidum *sine*, non *fœtidum cum*."

WATER CUSHIONS.—Mr. George Sampson, of Chester-street, Belgrave-square, claiming the merit of introducing the use of the water-cushion, made of the sheet Indian rubber lined with water-proof cloth, in inflammation and ulceration of the skin of bed-ridden persons; we deem it only justice to Mr. Hooper, the Operative Chemist, of Pall-Mall, to state that he mentioned the subject to us in the spring of the current year, and then proposed to communicate a paper on the advantages of *his* water-cushion to the *Medical Times*. The great superiority of Mr. Hooper's cushions consists in being made of vulcanized Indian rubber, which will bear water of any temperature, and do not become offensive. Our readers will do well to test and to examine both plans for themselves.

SANITARY CONDITION OF NOTTINGHAM.—A very interesting Report of the sanitary state of the town of Nottingham has just been published, from which it appears that, in consequence of the care and vigilance of the Committee, appointed to superintend the health of the inhabitants, cholera has not been so fatal among them as in 1832. The example of Nottingham, we hope, will not be lost upon other large towns, for it is evident, by what has been done there, the inhabitants have escaped a large amount of mortality and sickness. From the statements contained in the Report, the following conclusions have been drawn:—That a constant and plentiful supply of good water; clean, dry, and well-drained streets and courts; a considerable extent of extramural burying ground; an active foresight on the part of the authorities; favourable public opinion and co-operation; and prompt medical aid, are most important means of preserving public health and of saving many lives. The Report further shows, how much can be accomplished at little expense, when there is judicious management, for, while London has expended more than 50,000*l*. in sanitary improvements, with but little practical benefit, Nottingham has laid out 150*l*. with the best results.

INTRAMURAL INTERMENTS.—On Tuesday evening the National Society for the Abolition of Burials in Towns assembled at their rooms in Bridge-street, Blackfriars. The President, Mr. G. A. Walker, took the chair, and during the proceedings a letter was read from the Board of Health, stating that the whole subject of intramural interment would be shortly taken under its consideration, and that the Board would be happy to receive, either at a personal interview or by letter, any suggestion which the experience of the President enabled him to furnish. The Chairman addressed the meeting at some length on the uselessness of leaden coffins to confine the dangerous gases which emanated from dead bodies. He stated that he had collected a large body of facts on the subject of intramural interments, all of which he was ready to place at the disposal of the Board of Health; and he bore testimony to the anxious desire of the Board to have the present pernicious system completely and finally abolished. He was followed by Mr. G. Godwin, who proposed a resolution to the effect, that Mr. Walker be requested to communicate to the Board of Health, the Society's anxious desire for the speedy abolition of intramural burial, and that he be also requested to assure the Board that the Society would aid it by every means in their power to effect that great national object. The motion was seconded by Mr. Rogers, a surgeon, and carried unanimously. Mr. Robert Watt, one of the Deputation appointed to inspect the burial-place of St. Giles's, Camden-town, stated that it was in a deplorable condition, and that its close proximity to the workhouse made it extremely injurious to the inmates. Other gentlemen addressed the meeting with reference to the re-opening of St. Bride's burial-ground, and the present condition of that of St. Pancras, in which, on Sundays, as many as 50 and 60 interments often took place. Dr. J. Evans drew attention to the grave-yards in Manchester. The whole parish burial-ground in that town had, he said, been disposed of to the Manchester and Leeds Railway Company for about 13,000*l*., but no provision had been made for the interment of the inhabitants in a manner suitable to the requirements of the age and the public health of the town. The proceedings of the meeting terminated with the usual vote of thanks to the Chairman.

SUPPLY OF WATER TO THE POOR OF LONDON.—At a meeting of the Metropolitan Commission of Sewers on Tuesday last, it was stated that the medical house visiters in the City still complained of the very limited supply of water to many poor districts. In some houses, the water-butts are old and too small; in others there are no receptacles for containing water; the New River Company had also discontinued supplying the inhabitants twice a-day. We think that landlords ought to be compelled to fix in their houses large stone cisterns adequate to supply the whole of the inmates. In wooden butts the water speedily turns foul and offensive, and thus becomes a fertile source of disease to those who partake of it.

PROPOSALS FOR ERECTING A MONUMENT TO DR. NICOL.—This gentleman was for many years the leading Medical Practitioner in Inverness, and recently died from an attack of cholera. Dr. Nicol was not only eminent as a physician, but was highly respected as a magistrate of the town in which he resided. The proposal to erect a monument to his memory has been received with such favour as renders it likely that it will be carried out. We are glad of this; for, where the community admittedly owe a heavy debt of gratitude, it is most seemly and becoming, that they should give some sensible expression of the obligation. Were this more attended to—were it more customary than it is, to record the public sense of services which the public owes to its benefactors, the public would be the gainer. Were young and generous youth, and even calculating age, only frequently reminded, by suitable memorials arising in the public ways of our cities, that thus were they honoured who laboured for the public weal, many a bosom would be fired to follow in the same paths, and to earn the same honourable record.

FEMALE UNIVERSITIES IN GERMANY.—Professor Fröbel, of Zurich, has resigned his post in that city in order to proceed as Professor to Hamburgh, in obedience to the call he received some time back from certain learned ladies who are about to form a university for females. We are not yet told what particular chair he is to fill. Female Professors are to be appointed.

MORTALITY TABLE.

(Metropolis.)

For the Week ending Saturday, Oct. 20, 1849.

Causes of Death.	Total.	Average of Five Autumns.
All Causes	1028	1162
Specified Causes	1022	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	277	307
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	34	49
Tubercular Diseases	165	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	126	125
Diseases of the Heart and Blood-vessels	27	40
Diseases of the Lungs, and of the other Organs of Respiration	155	214
Diseases of the Stomach, Liver, and other Organs of Digestion	67	65
Diseases of the Kidneys, &c	13	11
Childbirth, Diseases of the Uterus, &c	6	10
Rheumatism, Diseases of the Bones, Joints, &c	5	8
Diseases of the Skin, Cellular Tissue, &c.	3	1
Malformations	4	4
Premature Birth and Debility	24	23
Atrophy	19	18
Age	42	57
Sudden	10	12
Violence, Privation, Cold, and Intemperance	40	36
Causes not Specified	1	4

The following is the number of Deaths occurring from some of the more important special causes —

Apoplexy	26	Heart	23	Phthisis	110
Bronchitis ...	42	Hooping cough	26	Pneumonia ..	80
Cholera...	41	Hydrocephalus	29	Scarlatina . ..	41
Childbirth	3	Influenza		Small pox ..	6
Convulsions ..	38	Liver	11	Stomach	5
Diarrhœa ..	51	Lungs...........	8	Teething	14
Dropsy	12	Measles	11	Typhus .. .	63
Erysipelas ..	8	Paralysis	18	Uterus	1

BIRTHS AND DEATHS.

	Births.	Deaths	Births over Deaths
Males	715	524	191
Females	648	504	144
Total......	1363	[illegible]	335

METEOROLOGY OF THE WEEK.

TO CORRESPONDENTS.

"Mr. Gilbert, Civil Engineer," writes us, from Falmouth, as follows:—"I hope the hints or observations I am about to throw out, whether in accordance or not with the medical practitioner's views, will be received in the spirit in which they are given. . . . From long exposure to extreme climates, I have been subjected to frequent attacks of diarrhœa, so much so, that at times I have been very ill with it. The remedies usually resorted to in these cases generally produced such an opposite effect, that I suffered just as much from that as from the former. One day, while labouring under one of these severe diarrhœtic attacks, a friend of mine, a non-professional, recommended me to adopt his remedy in such case, i. e., a strong dose of lemon juice. It astonished me not a little, I can assure you; my friend pressed it so strong upon me, and, assuring me he had never found it to fail, induced me to come to this conclusion that the stomach was surcharged with an alkaline matter and became neutralized by the acid. This led me to examine the discharge from the bowels, which I found of a strongly alkaline character, I lost no time in providing myself with a moderate-sized lemon, the juice of which I pressed out into a tumbler, to which I added a little warm water and sugar. The dose being thus prepared, I drank it off, and, to my surprise and pleasure, in less than twenty minutes, I found my stomach and bowels soothed and the complaint stopped, and this unaccompanied with confined bowels, incidental to a sudden stoppage of diarrhœa, but followed by regular healthy stools I have but rarely found it necessary to repeat the dose, and have used this remedy, when required, for the last ten years, and have recommended it, and have given it to hundreds, of all ages, with the same success I mild cases, I have found two ounces of the common lemon, or acid drops, sold by druggists and grocers, dissolved in warm water and taken, has effected a cure In fact, since I first resorted to this, I have never gone on a journey either by land or water, without providing myself with a supply of 'acidulated drops' When I have found the attack severe, and unable to procure a lemon, I have used citric acid, as procured from the druggist, which I have dissolved in hot water The acid should be strong, particularly if the attack is severe. I believe any of the vegetable acids will have the same effect It may sometimes occur, that a diarrhœa may result from an excess of acid, I need not say that a neutralization of that is as easily to be effected in the stomach, through the agency of an alkaline, as the superabundance of alkaline by an acid Having submitted to you the results of my own experience on myself and others, allow me to suggest to you the use of a strong acid in diarrhœtic attacks, which I am convinced will be found perfectly safe and if the acid be judiciously managed in the hands of a medical practitioner, it may be found useful in cholera cases also, at all events, as it appears in most cases, cholera is preceded by diarrhœa it follows very naturally, that if the causes of diarrhœa be stopped, the progress of cholera may be arrested also '—Mr Gilbert will observe, that we have inserted all that portion of his letter which can be considered of the least interest to the Profession We scarcely think lemon juice administered to *hundreds of all ages suffering from disease*, can be considered as a *hint* merely to the medical profession It seems to us very like practising medicine on a large scale,—like driving an engine instead of suggesting an improvement in the machinery We think Mr G will thank us for having omitted his explanation of the *modus operandi* of lemon juice, when we inform him that we certainly *intended* to report Dr O Shaughnessy and M Simon to have said, that the stools were *acid* in ordinary diarrhœa We are not confectioners, but we have been informed, that acidulated drops are, in the majority of cases, made of sugar, acidulated with *dilute* SULPHURIC *acid*, and *flavoured* with *essence* of lemon

"Dr Hilbers '—One motive present to our minds, when we drew up the Cholera Tables was that of framing them in such a manner that we might be enabled to separate cases of cholera from cases of cholerine, and so estimate the results said to have been obtained from the employment of any given remedy We still think our opinion of Dr Hilbers' cases correct, in some of them the stools were brown, the surface warm and the urine passed freely Dr Hilbers ought not to demand from us a greater amount of credence than we give to others He will see from the present number of our Journal, that his success, if his statement simply is admitted in that the mortality among his patients was only 25 per cent, is by no means marvellous, for of 39 cases referred to by Dr Hastings, only 25 per cent proved fatal, and of the patients treated in King's College Hospital, during the same time, even a smaller proportion died, i e, only 20 per cent In 1832 of 1100 cases of cholera said to have occurred at Nottingham, 249 proved fatal, i e, 22 6 per cent. If simple assertion is to settle the question, and Dr Stevens assures us that out of 1100 cases of cholera treated by his salines was only 6 per cent., Dr Hilbers must abandon his homœopathic remedies, and administer Dr Stevens' salines And we do not see how Dr H can refuse to admit that minim doses of bisulphuret of carbon are as useful as minim doses of spirits of camphor, or infinitessimal doses of arsenic.

"H P J, of University College," is informed, in reply to his queries, that, if our recollection serves us right, four complete *anni medici*, or three winter and summer sessions, with additional hospital attendance, is required for the University of Edinburgh. Residence is only necessary during one year We should recommend H. P. J. to write to the Secretary of the Edinburgh University upon the subject H P J must improve his Latinity.

"Dr. John H. Agar, of Antigua," is thanked for his notice of puerperal convulsions treated by the exhibition of chloroform. We hope to find a place in our next number for his communication.

"Dr. Stiff."—Many thanks.

"J. M. B."—Certainly not. There is no difference to be observed as to the dispensing of medicines, whether the practitioner is an *extra licentiate*, licentiate, or fellow of the College of Physicians. The "threatened" penalty is expulsion.

"Medicus, of Newcastle-upon-Tyne."—Singleton's Eye-salve, or Golden Ointment, is prepared with equal quantities of sulphuret of arsenic and lard.

"Mr. Vidal's" case of Placenta Prævia will appear next week. It is a valuable addition to the cases of Dr. Waller.

"Chirurgus" writes us, that the names of the contributors to a Medical Journal are to be found strung together as a standing advertisement in a penny publication. We think it highly derogatory to the Profession; but we question much the propriety of publishing the caustic *expose* of Chirurgus, particularly as in the present case the fault seems to be more with the Publishers than the contributors. Again, the tone of Chirurgus is not the tone we wish the "Medical Times" to adopt We are, it is true, the champions of the Profession, and although we may be called upon to reprove its errors, we must do it in a very different manner Will Chirurgus call upon us at an early opportunity?

"Cambria"—Dr Golding Bird's Lectures on Galvanism have just been just published, price 5s. 6d. We will consider Cambria's suggestion.

"Mr Quain" and our readers must accept our apologies An accident prevents the appearance, in the present Number, of the Professor's excellent Clinical Lecture on Staphyloraphy, or Fissured Palate, treated by Operation.

"Mr Smith, of Belper," is unavoidably postponed.

"A Student of the Microscope" asks, what proof there is that the bodies lately described by Mr. J G Grove are the real Cholera fungi? The question is not a very easy one to answer inasmuch as our ideas as to what the cholera fungi actually are have been very much unsettled of late but we believe the objects figured by Mr Grove to be nothing else than ordinary mould arising from decay We recommend him to apply his microscope to a fine old Stilton cheese, and if he still believes in the propagation of cholera by bodies like those he has figured, he will probably deny himself that luxury for the rest of his life

"An Old Student of St George's"—Received

"Dr King, Saville-row"—Received

"Dr John H Agar Antigua, W I, Paper on Puerperal Convulsions treated with Chloroform," received.

"Mr F. G Wells"—Received.

"A London Surgeon" asks —'Can a person possessing merely the diploma of the London College of Surgeons practise in England If not what more is necessary?" Yes as a surgeon, but in order to recover at law for medicine and attendance in what are considered *medical* cases, he must have the Apothecaries' licence.

"Veritas"—The certificate of cause of death appears, from the statement of our correspondent, to have been improperly given, the patient having evidently died from typhus fever

From a press of matter, the Report of the Medical Society of King's College is postponed to next week.

"A Perplexed Student."—Both hospitals mentioned are very good ones

"A Subscriber Clonmel"—We believe Dr Mead

"The Son of a Subscriber"—We are unable just now to lay our hand on the formulæ our correspondent requires, if by next week we should be able to do so, we will give him the information he asks.

"Dr. James Arnott"—We have to acknowledge the receipt of a letter from Dr James Arnott, of Brighton, the nature of which obliges us to give consideration to the subject before publication.

DISPENSARIES, &c, IN IRELAND.—A Parliamentary paper published on the motion of Sir William Somerville, the Secretary of State for Ireland, shows that the number of Dispensaries, Fever Hospitals, and Infirmaries for which county presentments were made in Ireland in the year 1848, amounted to 773 (against 813 in 1847); the amount of presentments was 83,508*l*., and the amount of subscriptions 33,393*l*., making a sum total of 116,902*l*. The total amount of the sums subscribed and granted for Fever Hospitals in Ireland at the presenting sessions preparatory to the spring assizes of 1849 was 7,885. The number of Fever Hospitals supported by the Poor rates in 1848 amounted to 233 under the temporary Fever Act, the cost of which was 81,448*l*.; and to 80 not under that Act, the cost of which was 21,789*l*.

MAGNETIZED BRASS.—The Rev. T. Rankin stated, at the last meeting of the British Association, that he had found the northern half of a brazen meridian of a celestial globe to be so strongly magnetic, as to deflect a small needle placed near it so much as eight points from its true direction, while the southern part of it seemed to be totally free from magnetism.

REPORT ON THE NATURE AND IMPORT OF CERTAIN MICROSCOPIC BODIES FOUND IN THE INTESTINAL DISCHARGES OF CHOLERA.

PRESENTED TO THE CHOLERA COMMITTEE OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, BY THEIR SUB-COMMITTEE, ON OCTOBER 17, 1849.

Royal College of Physicians, Pall-mall East, October 27, 1849.

Sir,—The following report was, in substance, laid before the Cholera Committee on the 17th instant; and we were then authorized to send copies of it to the members of the College. The epidemic was already rapidly declining, and it seemed desirable to make known the results of our inquiry before the opportunity of verifying them should be lost.

Dr. Jenner's observations, and, with a single exception, Mr. Marshall's, were included in the original draught read to the Committee. On the same day Mr. Busk communicated to the Microscopical Society his observations on the identity of some forms of the "Cholera bodies" with a species of uredo, the contents of bran-cells, and starch-grains, respectively. These have been imbodied in the Report, together with the result of Mr. Marshall's examination of bran-cells (made subsequently, but independently of Mr. Busk's), and the fact, that the smallest "Cholera bodies" are derived from chalk,—a result to which we were led by the remarks of Dr. Griffith on their physical and chemical characters.

We have the honour to be, Sir,
Your obedient humble servants,
William Baly,
William W. Gull.

We propose, in this Report, to lay before the Committee the results of some experimental inquiries on a subject which, within the last few weeks, has engaged much of the attention of the Profession. We allude to the discovery, by Mr. Brittan and Mr. Swayne, of Bristol, of peculiar bodies in the "rice water" dejections of Cholera patients; and to the statement that similar bodies have been found by Mr. Brittan in the atmosphere, and, subsequently, by Dr. W. Budd, in the drinking-water of infected localities.

These observations, on account of their important bearing, if true, on the Pathology of Cholera, seemed to us to demand a searching examination. We have, accordingly, given much time and attention to the subject. Having, in the first place, satisfied ourselves of the distinctive characters of the bodies found in the rice-water dejections, we next sought to verify the observations of Mr. Brittan and Dr. Budd with reference to their presence in the air and drinking-water of places infected with cholera. It was necessary that this part of the inquiry should not be delayed, for the epidemic had already reached its turning point, and it would, before long, have been difficult to obtain favourable opportunities for experiments of a satisfactory character.

Our inquiries were afterwards directed to the nature and properties of the newly-discovered corpuscles, and to the question of their occurrence in other diseases. In this investigation, we soon perceived that objects totally different had been regarded as identical; but we had arrived at no positive conclusion respecting those which seemed most characteristic of the cholera evacuations, when we received two important communications on the subject from Mr. Marshall and Dr. Jenner. The letters of these gentlemen are appended to this Report; but the results obtained by them are imbodied in it.

Our observations on the air and drinking-water of infected localities, twenty-four in number, gave uniformly negative results. With regard to the value of our experiments, taken separately, it will, we think, appear that many are liable to no objection. Some of those which relate to the drinking-water of infected places, are certainly wanting in the conditions which would make them convincing. But when it is considered that Dr. Budd believes he has detected the objects sought for "in great numbers," in such large bodies of water as the Float, at Bristol, and the Surrey canal, and that he represents them as being deposited in the sediment of the water, we shall not be thought unreasonable in having expected that they might be discovered in the cisterns of houses and public institutions in which cholera had prevailed severely, although it had ceased there for some days or weeks.

Nevertheless, a much larger amount of evidence would have been required to disprove the statements to which our observations refer, had those statements been unassailable from other points. But the facts to be detailed in the subsequent part of this Report, will show that the bodies found in the rice-water dejections have no peculiar relation to cholera; and, that if they should occasionally be present in the atmosphere, or impure water, this will not happen exclusively, or even especially, in districts infected with the epidemic.

We shall now submit the particulars of all the observations to the Committee, describing, first, those on the air.

MICROSCOPIC OBSERVATIONS ON WATER CONDENSED FROM THE ATMOSPHERE OF INFECTED LOCALITIES.

Two methods were employed for condensing the aqueous vapour. One was, to suspend in the air to be examined a glass funnel, nearly filled with a freezing mixture, its lower opening having previously been closed by a cork and covered with sealing-wax. The moisture condensed on the outside of the funnel, trickled into a small phial placed beneath. The second method was, to force air slowly, by means of bellows, through a bent glass tube immersed in ice and salt; when the moisture was deposited on the interior of the tube, and collected in a bulb at its lower part. In either way from half a drachm to a drachm of water was readily obtained.

Obs. 1.—In Millbank prison, from the 6th June to the 16th September, there occurred eighty four cases of cholera. The last patient began to suffer from diarrhœa on the 16th September, and died on the 25th. On the 19th, when he lay in a state of collapse, about a drachm of water was condensed from the air of a lobby which separated his small apartment from a water closet, in which his evacuations were emptied. The water thus obtained was submitted to microscopic examination the same evening.

Obs. 2 *and* 3.—On the same day (the 19th September), we accompanied Mr. Bayfield, one of the surgeons of the Union of St. Olave's, Southwark, to two localities in his district, in which cholera had been most prevalent, namely, English Ground, Bull Court, Tooley-street, and Gimber's Rents, Snow's Fields. In a ground-floor room of a house in the former court, a woman and child had died of cholera within a few days; and the husband, at the time of our visit, was in bed, ill with the disease. Nearly a drachm of water was obtained from the noisome atmosphere of this room.

In Gimber's Rents the drainage and the ventilation were as bad as possible. In several places we saw the openings of drains covered with matting, to prevent the escape of effluvia. We collected about a drachm of water from a house where a woman lay ill of cholera; her husband having only recently died of the epidemic. The water procured in these two experiments, was examined the same evening, and the examination of it repeated on several subsequent days.

From Gimber's Rents we brought away a piece of bread which had been long in the house, and which had not been cut for a week; a piece of butter, the surface of which was covered with dust; and a jug, which we found filled with drinking water. The examination of this water will be referred to in our second series of experiments. On the bread and the butter, no bodies like those observed in the rice-water evacuations could be found.

Obs. 4 *and* 5.—On the 22nd September, water was condensed from the atmosphere in two houses situated in St. Erman's Hill, near the Broadway, Westminster. Mr. Painter, Surgeon of St. Margaret's parish, to whom we had explained our object, conducted us to this locality, as, at that time, the chief focus of the disease. In one house (No. 21) a child lay dead, having been attacked with cholera the preceding evening. Two other cases had recently occurred in the same house. At No. 12 a child was ill of cholera; and a second had been removed, in the morning of the same day, to the Cholera Hospital, where it died. Mr. Brittan and Mr. Newport took part in the microscopic examination of the water condensed from the air in these houses, about an hour after it was collected; but, like ourselves, were unable to discover any "annular bodies." On the following day, the same water, as well as that procured in the second and third observations, was again examined by Mr. Brittan, and with the same result.

Obs. 6.—On the 6th October, cholera appeared amongst the patients in the insane ward of the Birmingham workhouse; many were attacked. On the 9th October, at our request, Dr. Fletcher, of Birmingham, kindly obtained for us some water condensed from the atmosphere of this ward, and likewise from that of one above it, when diarrhœa was prevalent. These specimens of water reached us, and were examined by us on the 11th October.

Obs. 7.—From the beginning of the month of October, cases of cholera had been numerous and fatal in the workhouse of the Walsall Union; partly imported, but partly occurring in inmates of the workhouse. When the epidemic was at its height, we obtained, through the kindness of Dr. F. Burton, of Walsall, about a drachm of water from the air of the room in which the greater number of the cases occurred. This specimen of water was condensed from the air on the 7th, and was examined by us on the 8th October.

The water condensed from the air in the several localities, and under the circumstances we have described, was, in each case, examined by us more than once. But the search for "annular" bodies, such as those found in the cholera dejections, failed, as we have already intimated. Neither cells, nor rings, nor anything bearing any resemblance to them could, in most cases, be discovered. We saw merely portions of gelatiniform matter containing bright points—sometimes finely granular, brownish masses, perhaps derived from smoke—and occasionally colourless, transparent particles, of a crystalline appearance, which may have been portions of siliceous dust. After the water had been kept some time, chains of delicate oval vesicles, like those of the torula of yeast, but much smaller, appeared in it. These were absent at first, and could not be mistaken for the cholera discs. Equally unlike those discs, were the three or four separate oval cells, which, in two instances, were seen in the water when first examined. They had a clear, single outline, and were not flattened.

MICROSCOPIC OBSERVATIONS ON THE DRINKING-WATER OF INFECTED PLACES.

Obs. 8.—On the 26th September, Dr. Snow kindly furnished us with a specimen of water from Albion-terrace, Wandsworth, a locality in which cholera had been very fatal between the 28th July and the 13th August. This water, which was very foul, had been taken from a tank at Albion-terrace on the 16th or 17th of August; but, as it had been kept so long before it was submitted to microscopic examination, it may be objected that, had "cholera fungi" originally been present, they might have become decomposed or otherwise destroyed.

Obs. 9.—A second specimen of water, sent to us at the same time by Dr. Snow, was obtained from a house in Gresse-street, Rathbone-place, in which five persons had recently died of cholera. The last case of the disease here occurred two days before the water was obtained from the cistern, and twenty-four days before it was examined by us with the microscope.

Obs. 10.—From the 31st August to the 7th September, four fatal cases of cholera occurred amongst the female prisoners in two wards of the Milbank Prison. The part of the building where these wards were situated was forthwith vacated. On the 19th September, a portion of water with sediment was taken from the cistern which supplied

those wards, the contents of this cistern having remained undisturbed since the removal of the prisoners to another part of the building. At the same time specimens of water were taken from the cistern of the female infirmary, where two fatal cases of cholera had occurred simultaneously with those above referred to, and also from the tank which supplies the whole prison. These three specimens of water were submitted to the microscope the next day.

Obs. 11.—The drinking-water taken on the 19th September from the house in Gimber's-rents, Borough, (see *Obs.* 3,) deposited a sediment which was carefully examined. The description of the locality has been already given.

Obs. 12.—On the 27th September we visited Crosby court, Bermondsey, an open space containing seven houses. Four cases of cholera (two fatal) had recently occurred in one of these houses, the others having escaped. The house in which cholera had been fatal was closed. But we found that the water used by the inhabitants of the court came from two pumps; one supplied from the Thames water, the other raising well-water, which was hard and ferruginous. On a strict inquiry it appeared that the Thames water was used for drinking in every house except the one in which cholera had appeared; in that house only the well-water was used. We brought away water from both pumps, and examined the deposits, which were abundant, on the following day.

Obs. 13.—We next went to Jacob's Island, Bermondsey, a most crowded and wretched part of the district, in which cholera had been very severe. It is a portion of low ground bordering the river, and surrounded by a shallow tidal ditch, which receives the contents of the privies on either bank. The water for drinking and other purposes, is taken for the most part from this ditch. We procured some water from the ditch itself, and also from two pumps supplied from it, situated in Gutteridge's-court, where deaths had occurred.

Obs. 14.—On the same day we also went to Hanover-street, Rotherhithe, a low and crowed cul-de sac. A woman lay dead of cholera in one of the houses; and other deaths had occurred. The water used, of which we procured a specimen, was derived from the Thames, through a pump which became dry at every ebb. Behind the houses, on the east side, was an open ditch, receiving the refuse from them and conveying it into the Thames, at a point close to the opening of the pipe which supplied the pump in the street.

Obs. 15.—In a house in Swan-lane, Rotherhithe, close to the Millpond, a man lay dead of cholera. The disease had been fatal in two adjacent houses. The woman, whose husband had just died, told us that she and most of the inhabitants took their water for drinking from the Millpond, which is a tidal ditch, serving as a sewer to the houses on its banks. We filled a bottle with water from this source.

Obs. 16.—Dr. Burton, of Walsall, forwarded to us, on the 7th October, three specimens of water from the workhouse, cholera prevailing at the time amongst the inmates. (See *Obs.* 7.) The first was from an open cistern fed by land drains, the second from a moat, the third from cisterns in the workhouse. The last water, which is that chiefly drunk by the paupers in the workhouse, is derived from the moat, but is filtered through charcoal and gravel. The deposits of all were carefully and repeatedly examined.

Obs. 17.—To Dr. Fletcher, of Birmingham, we are indebted for five specimens of the water which supplies the workhouse, forwarded to us at the time cholera prevailed in the insane ward of the establishment. (See *Obs.* 6.) The specimens included:—1. Clear water from the reservoir which is supplied from the river. 2. Sediment from the reservoir. 3. Clear water from the cistern of the workhouse. 4. Sediment from the bottom of the cistern. 5. Sediment from the side of the cistern. These specimens were examined on the 11th inst., and the examination of them has been most carefully repeated.

Obs. 18, 19, 20, 21, and 22,—were all made on water obtained for us by Mr. Hunt, one of the assistant-surgeons at the Westminster Cholera Hospital, from several parts of the district called Palmer's Village, which we have ourselves inspected. The names of the places are Goodman's Green, where the water used for all purposes is contained in a filthy open trough; Perrin's-place; a house (No. 3) in Perrin's-court, in which five cases of cholera (two fatal) had occurred; a house (No. 2) in Providence-row, where also there had been five cases (three fatal); and the Dispensary-Palmer's Village, at which two surgeons successively had been attacked with cholera, one fatally. Cholera had prevailed in all these localities, but not within a fortnight of the time when the water was taken for examination.

Obs. 23.—In a small house (No. 9) in Dorset-place, Vauxhall-road, three cases of cholera had occurred in succession; the first on the 5th instant, the second (fatal) on the 8th, and the third (also fatal) on the 12th. These cases were attended by Mr. Clark, of St. James's-terrace. On the 8th instant, just after the second case occurred, two specimens of water were, at our request, taken from the butt supplying the house,—one from the surface of the water, the other from the tap after the sediment had been stirred up; and both have been several times examined with the aid of the microscope.

Obs. 24.—On the 5th October a man labouring under cholera was admitted into University College Hospital. He had resided for some months at No. 4, Howland-street. A week previous to his attack he had changed his room to another in the same house, where a woman had died of cholera seven weeks before. Water was taken from the kettle, and from a stone water jug in his room, as well as from a cistern which supplied the house. As he had dined in another house on the day previous to his attack, water was procured thence also. The deposits of these several specimens were likewise submitted to careful microscopic examination.

The uniform result of these experiments, as of the former series, was negative. No bodies were found which could be regarded as identical with the more characteristic of those discovered, by Messrs. Brittan and Swayne, in the rice-water dejections of cholera. The objects met with were far more numerous than those seen in the moisture condensed from atmosphere. The sediment, when viewed with the 1-8th-inch object glass of Ross, or 1-16th-inch object glass of Powell and Lealand, presented, besides amorphous matter, an almost endless variety of organic forms, both animal and vegetable. Amongst these were many round or oval cells, of various dimensions, and some separate rings of minute size, colourless, and pellucid. The cells had generally very delicate walls and a clear cavity, were never flattened, and often contained a multitude of distinct granules, which, in some instances, presented the molecular motion. Like the rings, these cells were obviously different in their nature from the thick edged discs, which the descriptions and drawings of Messrs. Brittan and Swayne and Dr. Budd had led us to regard as the characteristic corpuscles of the cholera evacuations.

The negative results of our search in the atmosphere of infected places, for objects identical with those just referred to, are confirmed by some observations communicated to us by Mr. Marshall. While cholera was prevalent in St. Giles's, he examined the dirt washed from the broken glass of windows, and from cobwebs taken from houses in that district, in which deaths had occurred from four to ten days previously. With 1-12th inch or 1.8th inch object-glass, he found a vast number of objects, such as particles of silex and soot, hairs, wings, and legs of insects, round and oblong cells of a brownish colour, very dark spherical granular masses, probably of a confervoid nature, and fragments of vegetable tissue, amongst which were pieces of spiral tubes, and entire rings, apparently of woody tissue, of an oval, polygonal, or circular form. But he detected no discs with double outline. A microscopic examination of the objects collected on a moist surface from the atmosphere of sewers, gave Mr. Marshall a similar negative result with regard to those discoid bodies; although he found (besides fine particles of silex and other dust) brown, oval, and round cells, single and in couplets, minute colourless vesicles, either single, double, or in triplets, a single large oval cell, and numerous opaque granular confervoid bodies, of a brownish or blackish green colour.

MICROSCOPIC OBSERVATIONS ON THE BODIES FOUND IN THE CHOLERA DEJECTIONS.

We next proceed to show how various are the bodies which have been confounded together under the terms annular bodies (Mr. Brittan), Cholera cells (Mr. Swayne), and Cholera fungi (Dr. Budd).

On examining the drawings given by the three gentlemen who have called attention to the subject, four principal forms, which can hardly belong to the same objects, may readily be distinguished.

1. *Rings*, which enclose a free area, and which often are broken. These are usually of minute size according to Mr. Brittan and Mr. Swayne, but occasionally large, according to Dr. Budd. (a.)

2. *Globular or oval cells*, chiefly of the middle size, which have a thick wall with numerous small eminences on its surface and contain a granular mass, in some instances separated by a clear space from the wall of the cells. These are distinctly figured only by Mr. Swayne, but are regarded by him as perfectly developed cholera cells.

3. Bodies having apparently the form of *discs, with thick rounded edges*, and centres of indistinct structure. These vary extremely in size, including some of nearly the smallest, as well as many of the largest, of the objects represented by the three observers. They predominate in all the representations given of the corpuscles of the rice-water dejections, and must be taken as the type of the bodies discovered by Messrs. Brittan and Swayne.

4. Large *broken cells*, having apparently homogeneous membranous walls, and containing small, well-defined, oval bodies; figured by Dr. Budd as cholera fungi undergoing decay, but differing in character from all the other objects represented.

A mere inspection of these different figures would suggest strong doubts as to their representing different appearances of really identica bodies in different states or stages of development or decay. The more particular description we have now to give of each kind of body, will demonstrate that they are of various and distinct nature.

1. The rings, when closely examined, are seen to be of different kinds; some perfectly continuous in their entire circle; others formed by a curled fibre; some round, some oval, others lozenge-shaped.

Some of these have been traced to their true source by Mr. Marshall, who has found that exactly similar objects may be prepared by the artificial digestion

---

(a) [By omitting the references to the many engravings contained in the Report of the Cholera Committee of the College of Physicians, we have been obliged slightly to alter the text. Our readers will not, we think, accuse us of any unwillingness or backwardness in laying before them illustrative engravings, whenever, by doing so, we can enhance the value of the various communications that appear in our Journal. In the present instance we would have gladly repeated the figures to which we allude; but the period of the week at which we received the Report, and our anxiety not to postpone the publication of so valuable a document, which, at present, is circulated only among the Fellows and Licentiates of the College, have rendered it impossible to carry our wishes into effect. In the present case, however, we do not so much regret our inability, as, under different circumstances, we should have done. In the first place, we have the satisfaction to announce, that the Cholera Committee have resolved to *publish* their Report; and in the second, the doctrine of the "Cholera Fungi" having been proved to be untenable, it will soon pass away, be forgotten, and heard of no more, except as a warning to men not hastily to arrive at conclusions, nor to seek the "bubble reputation," without a surer foundation than this upon which to rest their claims.—ED. *Med. Times.*]

of the vegetables used as food—such as cabbages, potatoes, and onions, the withered style of wheat grain, and portions of cane in sugar; the spiral and annular tissues of which break down into rings of different sizes, or coils resembling rings.

Intermediate between these and the third class of bodies are minute, oval or round, colourless cor puscles, which have an annular appearance; but, on close inspection, are seen to have their area filled up with a transparent substance, presenting sometimes perforations. In some specimens of the rice-water fluid, oval bodies, in part having their middle filled up as here described, and, in part, mere rings, exist in extraordinary abundance. The rings of these bodies have been observed, by Mr. Busk and Dr. Griffiths, to be divided, by cross-lines, into segments, which Mr. Busk thinks are bead-shaped—an appearance which had occasionally been noticed by ourselves as well as by Mr. Marshall. They are calcareous structures, originally derived from chalk, in which they abound; and they have been introduced into the contents of the intestines with the medicines (chalk-mixture, aromatic confection, &c.) which the patients have taken. (a) These minute bodies from the chalk are, of course, not found in all cases; and we think it not unlikely that, in their absence, the separated nuclei of animal and vegetable structures, as well as the vegetable rings above described, may sometimes have been mistaken for fungi.

2.—The globular bodies have been clearly identified by Mr. Marshall with the spores of different kinds of uredo, the rust, smut, and bunt of grain; some species of which may be found, not only about the withered style on grains of wheat, but also in almost every specimen of corn and bread.

Mr. Busk has made the same observation, and identifies them with the uredo segetum, or bunt.

3.—Discs, with thick, elevated, and somewhat irregularly-curved margins; the central area flattened, and obscurely granular. They have generally a yellowish, or pale brown tint, which varies in depth with the colour of the fluid containing them. These are the most peculiar of the bodies found in Cholera, and differ from the rest in being more or less soluble in ether. Mr. Marshall, who first informed us of this fact, found that the smaller discs undergo nearly complete solution, leaving a cavity in the dried mucus, whilst the larger ones leave a fine granular film. They are apt to break across, and the thick margin to curl inwards. They are evidently not cells, nor have they any organized structure which could give them any claim to be regarded as living organisms. On the other hand, their solubility in ether shows that they consist, in great part, of some substance of the class to which the fats, resins, and saponaceous matters belong. This observation led Mr. Marshall to examine different fatty substances, and at length to find that curled concretions, not unlike the discs found in cholera, could be obtained by compressing a piece of rich cheese (with or without the addition of ether) between two plates of glass. We are not yet able to account for the origin of these peculiar discs.

(a) It is right to state how we arrived at the knowledge of these facts. Dr. Griffith had pointed out to us that the bodies in question are heavy, polarize light, and are soluble in dilute nitric acid. He suspected that they were oxalate or phosphate of lime. Mr. Marshall subsequently showed us that acetic acid also dissolves them readily, and that sulphuric acid acts on them, producing needles of sulphate of lime. Having ourselves found the same bodies in the evacuations of two patients suffering from typhoid fever, we were examining them in company with Dr. Griffith and Mr. Marshall, when the demonstration of their calcareous nature reminded us of the fact, that these patients had been taking medicine containing chalk, and, at the same time, brought to our recollection the remark made to one of us by Mr. Topping, that Mr. Brittan's "annular bodies" were to be found in chalk-mixture. Accordingly, we examined a portion of medicine containing aromatic confection, and, afterwards, a piece of common chalk, and, in both, found the bodies described above, though not the larger discs which are also found in the rice-water fluid. Ehrenberg figures these calcareous bodies, and describes them as being "crystalloids." Abh. d. Akad. d. Wiss. z. Berl. 1838, p. 68.

Mr. Busk regards the smaller ones as altered starch grains. It is, at all events, certain that they are not fungi; and, as we shall afterwards see, that they are not peculiar to cholera.

Mr. Busk thinks that the larger discs are the altered contents of bran-cells. Mr. Marshall, too, has, independently, made the observation, that certain yellowish bodies, sometimes seen, which have a thinner and narrower border than the fatty discs, and are merely rendered pellucid by ether, may, perhaps, be derived from bran. The granular masses contained in bran cells have, however, when undigested, no distinct border.

4. Under the fourth class of bodies, we refer to those represented by Dr. Budd as the cholera fungi undergoing decay and disintegration. They are evidently of a different nature from those figured by him as characteristic of the fresh cholera dejections. The mode of disintegration of the two classes of bodies is quite distinct: the so-called cholera bodies, after resisting the action of water for some time, break up into irregular granular masses; whilst the decomposing bodies depicted by Dr. Budd, seem to be, in part, homogeneous, membranous cells dehiscing; and are, perhaps, starch cells. The rings are, most probably, parts of disintegrated vegetable tissue.

It is shown by Mr. Marshall, and had before been noticed by Boehm and others, that cells like fungi, or their spores, are occasionally found in the excretions in cholera. These, however, have a more delicate structure than any of the bodies described as characteristic of cholera, and are totally different from them. It is well known that various vegetable forms are apt to become developed in organic fluids generally.

From a review of the foregoing facts, it is obvious that various bodies found in cholera dejections have been confounded, and described as identical. It is also shown, that many are traceable to an extraneous source, and that even the discs placed in our third division, are not fungi. The statement, that the bodies found in the cholera dejections present an endogenous multiplication, has, in all probability, arisen from confounding them with the uredo, or from mistaking the appearances produced by the small bodies seen through, or upon, the larger ones, or entangled in their substance.

We are unable to identify the rings obtained from the air, and figured by Mr. Brittan, with any of the bodies included by him under the term "annular bodies." Our own experiments have satisfied us that these bodies do not commonly exist in the atmosphere of infected places, but the observations of Mr. Marshall, on the dirt collected from windows and cobwebs, show the great variety of matters which must be wafted about in the air, in the form of dust, and which might, in different instances, be caught with the condensed moisture.

The bodies represented by Dr. Budd, as being found in impure drinking water, have the form of discs with thick edges. We have ourselves never seen such bodies in water. But, if it should be established that the contents of bran cells sometimes assume that form, the occasional presence, in water, of bodies capable of being confounded with the discs derived from the discharges of cholera, will not appear remarkable.

Had the bodies described by Messrs. Brittan and Swayne been proved by the foregoing investigations to be of fungoid nature, yet the facts we have now to add would have shown that they have no necessary connexion with cholera. In the first place, they seem not to be constantly present in the discharges. It is, indeed, remarkable that, in those dejections which, from the absence of colour, have usually been regarded as the most characteristic of the disease, they are frequently absent. We have failed to find them in several instances. In one, a portion of every evacuation was set apart, and examined several times by each of us, and yet in no portion would we detect them.

A still more important fact, which, from the explanations already given might be anticipated, is, that all the more remarkable of the bodies which have been thought peculiar to cholera, exist in the intestinal evacuations of persons affected with other diseases. Dr. Jenner first demonstrated to us their presence, in great abundance, in the dejections of a patient affected with typhoid fever. We have since verified his observation in five other cases of this disease. We have also satisfied ourselves of the existence of some of the forms in dejections apparently healthy, from two patients in Guy's Hospital, one suffering from bronchitis, the other from early cirrhosis of the liver; and Mr. Marshall has detected small annular bodies "in the mucus covering the healthy excrement" of several herbivorous animals. It is obvious, that bodies derived from such various sources will not commonly be found all present together. This, indeed, is not the case in cholera. The minute bodies, especially, which belong to chalk will, of course, very rarely be met with, except that substance has been taken as medicine.

We shall now briefly re-state the principal results we have arrived at, and submit the conclusion which seems to us justified by them.

1. Bodies presenting the characteristic forms of the so-called Cholera fungi are not to be detected in the air, and, as far as our experiments have gone, not in the drinking water of infected places.

2. It is established that, under the term "annular bodies," "Cholera cells," or "Cholera fungi," there have been confounded many objects of various, and totally distinct, natures.

3. A large number of these have been traced to substances taken as food or medicine.

4. The origin of others is still doubtful, but these are clearly not fungi.

5. All the more remarkable forms are to be detected in the intestinal evacuations of persons labouring under diseases totally different in their nature from cholera.

Lastly, we draw from these premises the general conclusion, that the bodies found and described by Messrs. Brittan and Swayne are not the cause of cholera, and have no exclusive connexion with that disease;—in other words, that the whole theory of the disease which has recently been propounded, is erroneous as far as it is based on the existence of the bodies in question.

(Signed)

William Baly, M.D., } Cholera
William W. Gull, M.D., } Sub-Committee.

LETTER FROM DR W. JENNER, ASSISTANT-PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

"Albany street, October 17, 1849.

"My dear Sir,—On reading Messrs. Brittan and Swayne's papers, it appeared to me that the bodies they described as cholera fungi, bore a very close resemblance to objects I had long since observed in examining microscopically dejections passed by patients labouring under typhoid fever. That they were identical, whether of vegetable origin or otherwise, seemed to me the more probable, because of a certain resemblance in the chemical constitution of the evacuations in the two diseases.

"My colleague, Dr. Parkes, found, when analyzing, at the early part of the year, several dejections passed by patients suffering respectively from typhoid and typhus fever, that while the latter were acid and contained no albumen, the former were alkaline and albuminous. Understanding that the microscopic vegetations which flourished in alkaline fluids are not to be found in acids, it struck me that such peculiarity in the nidus, suited for different vegetable growths, might account for Drs. Brittan and Swayne having failed to detect the "cholera fungi," (if these bodies are vegetable,) in the stools passed by patients affected with typhus fever or bilious diarrhœa. Dr. O'Shaughnessy stated, in 1832, that he had tested the stools in 100 cases of bilious diarrhœa, and found them all acid, and without a single chemical character of cholera stools. Simon also says, that in bilious diarrhœa they are acid. On examining microscopically four alkaline stools, passed at different stages of typhoid fever, I found in them bodies which appeared to me identical with those described and figured by the members of the Bristol Committee.

"The bodies I have observed consist of the ring

with double outline, and others corresponding to the more developed forms of 'cholera fungi,' figured by Mr. Swayne. I have seen none of the most highly developed forms. Floating through the liquid part of one dejection were numerous minute jointed threads. I may mention that the former bodies were found to exist most abundantly in the *pale* yellowish particles floating through the typhoid stools, some of which appeared almost entirely composed of them.

"I am, my dear Sir,
"Yours faithfully,
"Dr. Baly." "W. Jenner.

LETTER FROM JOHN MARSHALL, ESQ., ASSISTANT-SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

"Mornington-crescent-place,
23rd October, 1849.

"Gentlemen,—I beg to submit to your consideration the following results of an examination of the minute bodies which have been recently pointed out as existing in the evacuations of cholera patients.

"1. In the *dejections* or in the contents of the intestines of cholera patients after death, I have, in the majority of instances, recognised all the forms of microscopic bodies described as being found therein, and represented by Messrs. Brittan and Swayne, and by Dr. W. Budd. These I have examined under high magnifying powers, (using a one-eighth or a one-twelfth of an inch object-glass,) and have submitted them to various re-agents. In order to obtain objects for comparison with these bodies, I have digested, with pepsin prepared from the sheep's stomach, the common articles of vegetable diet. Not one of the re-agents which I have employed appears to have acted uniformly upon all the cholera bodies. Neither alcohol nor ether, when applied to the moist mucus in which they lie, produce much effect upon any of them; but when the mucous is spread out upon glass, and allowed to dry spontaneously, either of these agents, especially when pure, almost entirely dissolves the *substance* of a certain number of them.

a. The bodies thus acted on by ether vary in size, from the smallest up to those which are rather *under* the medium dimensions, and are plainly distinguishable from the particles of solid and globules of liquid fat present with them. They have a bright, transparent, yellowish hue, resemble flattened discs in form, are cupped, or irregularly depressed in the centre, and have a more or less distinct double outline. The smaller ones appear homogeneous in substance; and in them, the faintly-marked inner line corresponds pretty accurately with the outer margin; but in the larger kinds, which are granular in the centre, the thickened border between the two lines is irregular in width, or seems as if it were formed by the union of two or more *curled* portions. These bodies are not acted on by iodine or chromic acid; they preserve well in thickish mucus, or in strong saline solutions; but in more watery dejections, in dilute aqueous solutions, or more readily on the addition of water, they slowly disintegrate and break up after the manner of fat. When dissolved by ether, the smaller ones leave behind merely a space or mould in the dry mucus; but in the place of the larger ones, there is certainly an appearance of a thin film, within or upon which, besides some irregular granules, one or two of the smaller annular bodies which resist the action of ether may, though not constantly, be found.

The origin and meaning of these fatty (?) bodies is a subject for further inquiry. They may originate in the secretions of the digestive organs, or be produced from fat taken as food; or they may have some relation to the dextrine into which the starch grains are converted in the alimentary canal; for fat is known to appear, under certain circumstances, during the decomposition of saccharine solutions. That fatty substances may crystallize in somewhat similar forms to the bodies just described, may be shown by digesting sour cream or cheese in alkaline solution or in ether; or, as I afterwards found, much more simply by compressing a small piece of rich cheese, moistened with ether, between two plates of glass, when a multitude of minute *curled* concretions of fat are seen under a high magnifying power, similar to, though of course not identical with, the class of cholera bodies now under consideration.

"Some of the bodies shown by Dr. Jenner to exist in typhoid dejections are of the same nature.

"A large proportion of the cholera bodies, however, of all sizes, but especially of the smallest kind, resist more or less the action of ether; and these, as well as the empty places or husks of such as are more or less dissolved by that menstruum, may be conveniently displayed and preserved, after the evaporation of the ether, in mastic varnish, covered with thin glass. The larger and smaller bodies not dissolved by the ether, may, I think, be referred to the following heads.

"*b*. Numerous *yellowish* bodies *above* the medium size, having a round or oblong form, a hard outline, an irregular rim or border, and a granular centre, which is either scarcely cupped, flat, or even slightly embossed. Iodine does not colour them; they decay in water; but, after longer time than those previously described; in ether, they become colourless and transparent, especially in the centre, crack in angular lines, and, in some cases, under slight blows, the rim appears to fall away in pieces and leave a central, well-defined mass. One or more of the small annular bodies are frequently found lying upon them, and occasionally appear to be in them or beneath them; but I have never seen a *groupe* of smaller bodies within a larger one.

"Having found cells of this kind abundant in the case of a patient who had eaten daily of walnuts previous to his attack, I digested artificially and examined portions of that fruit and its skin. Beneath the epidermic layer are found polygonal cells containing a *coloured* granular matter differing from those composing the oily substance of the nut. In the cabbage and onion greenish and yellowish cells are found, also differing in their contents from those amongst which they lie; and, lastly, beneath the outer skin of the potatoe, and that of the grains of wheat and barley, *coloured* cells exist, perfectly distinct in character from those containing the starch granules. In the walnut, wheat, and barley, they are somewhat flattened, and have a fusiform or polygonal, or even a roundish outline. They resolutely resist artificial digestion. By maceration in liquor potassæ, and the subsequent addition of water, (under the microscope,) they swell, sometimes separate from each other, and become more or less rounded in outline. Those obtained in this way, from the softened cotyledon of wheat, are coloured *yellow* by the alkali, and display a pale, central spot, which, by prolonged maceration, becomes larger, and pushes towards the margin of the cells, their granular contents; on bursting them, a thick, limpid, oily fluid escapes. Ether causes them to shrink. In size, colour, and form, they very much correspond with the larger cholera bodies just now described. A close imitation of the changes incident to digestion might establish their identity. Certainly flat, yellowish, polygonal or fusiform bodies, resembling these cells unaltered, do exist in cholera and typhoid evacuations.

"*c*. Another set of bodies, not nearly so numerous as the last, but also above the medium size, and having a rounded form, are characterized by their deep yellowish, or brownish-red colour, their decidedly spherical shape, and their hard and finely-indented outline, within which one or two other concentric and similarly indented lines may be traced. The surface of some is faintly marked with a polygonal tesselation; in others, which are usually larger, this is no longer recognizable. Water distends them; iodine gives them colour; and ether or alcohol greater definition. These are the spore cases of different species of uredo.

"In artificially-digested white and brown bread of the best quality I first found similar bodies; and, subsequently, in different samples of fine flour. Four to six occur in as much flour as will lightly cover a sixpence; and, in a cubic inch of bread consumed at my own table, as many as 150 must exist. Finally, in two separate specimens of wheat of this year's growth I have found them entangled amongst the fine hairs surrounding the withered style and pistils,—in numbers, from one to eight upon a single grain, though occasionally none could be detected. Usually, I have met with the orange-yellow spore cases of Uredo rubigo or rust; more rarely, and only in bread, with the larger and darker sporidia of Uredo fœtida or smut-balls, or of Uredo segetum or bunt.

"Those found in cholera dejections appear to be often partly digested, being soft, pale, flattened out, and even emptied of their contents. In one typhoid evacuation they existed in great numbers, and were only very slightly altered in appearance.

"By far the most numerous of the so-called cholera bodies are the small annular bodies, both oval and circular. Their great abundance and variety of size, are well seen in specimens treated with ether, and put up in mastic varnish.

"*d*. Some of these, whether oval or circular, which are not rings, but have an annular appearance, owing to their double outline, (fig. 10,) have, as was pointed out to me by Dr. Baly, all the characters of epithelium-nuclei from the alimentary canal, altered or simply set free, by the digestion of their containing cells.

"By artificial digestion I have succeeded in imitating the appearances of many, but not all of these bodies, with their bright surrounding border, and their central substance and nucleoli.

"*e*. Another set of the small annular bodies, *not so numerous* as those last described, consists of *true rings*, as may be determined by the fact of the inner bounding line being as dark as the outer one. In prepared specimens they are recognised by their oval and compressed form, homogeneous glassy character, and their dark outline. Sometimes the ring appears thicker, and at others, as if broken at some point. Frequently mere fragments are met with.

"Exactly similar objects may be prepared by the artificial digestion of the vegetables used as food. The spiral tubes and annular tissue of plants, break down sometimes into simple entire rings, sometimes into portions of fibre, which coil up and show their overlapping ends only to a practised eye. From the cabbage and onion, from the cooked potato, where these tubes form part of every bud or eye, even from the withered style of the wheat grain, and from fragments of the cane in coarse sugars, spiral tissue, of various diameters, is met with, some of the tubes being not more than 1-4000th of an inch in diameter. The inner rims of the stomata of plants, and the margins of flattened cells may also furnish rings of various size and form.

"Furthermore, in the mucus covering the healthy excrement of the goat, rabbit, and guinea pig, I have found similar rings of vegetable tissue.

"*f*. There still remains a series of minute bodies, some oval and others circular, which have an annular appearance, but which, owing to their extreme precision of form and smoothness of outline, are not referrible to either of the three kinds yet described. Some, which are oval, appear like minute clear cells, or like the remains of such cells ruptured. Very small circular bodies have the same characters. Probably these are really the spores of fungi, or are cellular fungi introduced with the food or drink, and only imperfectly digested. The cells of the yeast plant are to be found in moistened bread. As we have already seen, smut balls are actually introduced into the digestive organs with bread; and, in examining the hairy tufts on grains of wheat, I found the spores of *two* other fungi,—one, rare, the other in larger numbers. On the skin of the walnut I found no less than *four* different fungi, with their sporules; and others in digested cabbage. Minute vegetable cells also exist in water. Where the digestive process is nearly arrested, as in cholera, the remnants of these fine cellular bodies might appear in the dejections.

"*g*. Certain circular rings, with a bead-like appearance, also seem to me to be peculiar.

"*h*. Lastly, I have occasionally seen in the rice-water fluid and its sediment, colourless, transparent vesicles, varying from 1-3000th to 1-1000th of an inch in diameter, and presenting, when focused

at their middle, a brilliant, but very fine, double outline. They are destroyed by desiccation, and, after a few days, disappear from the fluid which at first contains them. They are distinct from any of the bodies previously noticed, but resemble some which I have seen in the fresh urine passed after the stage of collapse.

"In conclusion, I may state that, whatever be the nature and meaning of the bodies described in Section *f*, which are probably introduced from without; and of those in Section *h*, which perhaps are formed as the accompaniments of a particular state of the fluid in which they are contained, I can trace no specific relations between these and any other series of the cholera bodies; nor does there at present appear to me to be satisfactory evidence of the existence of any living organism, animal or fungoid, actively developing itself, and multiplying in the interior of the alimentary canal, in cases of malignant cholera.

"The foregoing observations apply entirely to the objects seen in the intestinal discharges. My examination of the matters vomited, in four instances, has led to merely negative results.

"In five cases, in which both serum and clot of the blood were examined, no annular bodies of any kind were found.

"I have the honour to be your obedient servant,

"JOHN MARSHALL.

"To the Cholera Committee of the College of Physicians.

"Postscript.—In a case of typhoid fever and pneumonia, I find in the bile contained in the full bladder, three days after death, small, roundish, fatty masses, having a bright rim and double outline; the largest having, moreover, a curled margin. The observation affords additional evidence of the proneness of fat to assume such form, and suggests the possibility of the bile being concerned in the formation of the 'bodies' described in section *a* of this letter. "I. M.—October 29th."

ORIGINAL CONTRIBUTIONS.

STATISTICS OF THE CHOLERA IN THE METROPOLIS FOR 1848, 1849.

By Mr. BENJAMIN SMITH.

If we were asked to assign reasons (humanly) why the cholera has committed such ravages among us in the year 1849, we might give as one of those reasons the fact, that in 1832, when the same disease prevailed to a great extent, the phenomena attending it were left in a great measure unstudied, and to a greater extent unrecorded,—so much so, that in the latter case, details respecting the course and peculiar features of the disease are barely to be got at, and, when obtained, they are so imperfect as to be of little use in comparing that outbreak with the one which has so recently visited us. The present registration system, not having been established in the former period, we are destitute of the advantage of that most elaborate portion of statistics, and Medical men themselves, not having been acknowledged as hygienists, only as curers,—the predisposing causes of cholera, which might have been elicited in 1832, devolved no special duties on those who had made the constitution and frame of man their peculiar study, but left the public health to be dealt with on the arena of polemics, by a Board of experimentalists without either knowledge or experience, by parish-officers in vestry assembled, and by landlords who are never "too fast" in sanitary improvements. Thus was it with the epidemic of 1832. Shall it be so with that of 1849? With a mass of statistics most carefully provided at the public expense, shall they be deposited on the shelves of all the Blue-books, only to be cleared of their dust by some single-handed philanthropist, who, because he *is* single-handed, shall be treated as a schemer; or, shall the whole body of the Medical Profession handle and deal with them as a primary duty connected with their high calling, and, by the manner in which they discharge that duty, stamp their mission as at once that of the patriot and philanthropist, and for which the ancient myth had discovered no imbodiment.

Bare as are the details for 1832, they yet present so many points of resemblance in the progress of the disease then, and in the present year, that we cannot forbear saying (what should not be lightly said) that, humanly, hundreds, if not thousands of lives have been sacrificed to the grossest neglect, only wanting the ingredient of "malice-aforethought" to constitute it murder. Why, if certain conditions were known in 1832 to favour the dissemination of cholera, and were removable by human means,—why were these same conditions left untouched, not to say made worse, for seventeen years, then again to aid in depopulating our cities, and causing the bosom of society again to heave with the throes of anguish? Why? and I answer, greatly because sanitary measures were left to men whose professed business it was to mind *other* things, and whose ignorance incapacitated them for *this* one thing,—while they upon whom it naturally devolved, either did not recognize the full scope of their mission, or were ousted of their proper jurisdiction to make way for class interests, the public health notwithstanding. Will the Profession, which has just emerged from a trial having no counterpart for nearly 200 years, will they who have been so lately called upon to experience the weakness or the futility of their efforts to stem the torrent, and many of whom have been obliged to retire from the scene with broken health and broken-down spirits, as, one after another, their cases defied all attempts at cure,—will this Profession, so tried, so baffled, sink down in despair because the cholera could not be cured where it might have been prevented, or will it not the rather rise above the depressing influences of a temporary defeat, to fight the good fight of prevention against the enemy of man's progress to three-score years and ten?

If I might mention one argument where so many press their claims, why such a course as that just mentioned should be pursued, it would be this—that in the recent visitation the cholera has taken from us especially, not the young, not the aged, but the very vigour of society. All can rejoice in the freshness and beauty of the opening bud, and still entwine around the old trunk that has long since passed bearing fruit, and neither do we complain that it cumbers the ground; but society can ill afford to lose its trees bearing fruit,—we can ill spare, beyond the common rate of mortality, a large proportion of the most vigorous understandings and most stalwart frames. Yet such has been a marked feature of the epidemic.

For these reasons, and many more, I would invite the Profession to gather up every scintillation of light that is developed with respect to this disease, and not, by neglecting one part of its phenomena, while they attend to that which they conceive belongs more exclusively to medicine, give the opportunity to others (incompetent) to take a part of their calling upon them, and thus deprive the Medical man of the high honour of building up his fellow-being in health and strength, instead of rescuing him from the jaws of death, and then only with a shattered frame. For each one to do well his part, so far as means allow, will at last aggregate a mass of knowledge around which future generations may gather to learn wholesome truths and receive timely warnings; and it may be received by the Father of us all as at least some acknowledgment for spared life, that we make good improvement of all our experiences, and use life that we may be useful to the living. In order to this, I have gathered up such statistics with regard to 1849 as have come to my hands, and which are here detailed; of course premising, that I am indebted to the Registrar-General for the means of arriving at the greater part of the results obtained.

The total number of deaths from cholera in the 54 weeks, from Oct. 1, 1848, to Oct. 13, 1849, amounts to 14,497, or 5,489 more than occurred in 1832, among a population, by the census of 1841, of 1,948,369, or as estimated to the middle of 1849, of 2,206,076; being 1 death by cholera in every 134·4 of inhabitants by the census; or 1 in 152·2 according to the latter estimate. From this number of deaths, it appears that the cholera has taken off, in the above period, the whole increase of population which accrued in 1848, and somewhat more, that increase having been 13,104, and is within 4,000 of the number dying from zymotic diseases (18,117) in that year.

We shall now consider this number of deaths as it relates to Sex, Age, Trade or Position, Duration of Attack, District or Locality, Meteorological Phenomena, and Season or Period.

I. SEX.

The deaths in this respect are 6,914 males, to 7,583 females, giving a preponderance as it respects the latter of 669, thus reversing the law which generally holds in respect to diseases from all causes; but still further peculiarities as regards sex will appear, in considering

II. AGE AND SEX.

Of the gross number of deaths from cholera, 4,447 die from 0 to 15 years of age; 8,629 from 15 to 65; and 421 from 65 and upwards, including 14 with age not specified, being a deviation from the usual course of zymotic diseases, by which most deaths occur from 0 to 15, and one which has generally been found to hold, as it respects this disease, wherever it has prevailed. Thus, in the *Berlin Cholera Gazette*, we find, that out of 2,000 cases of cholera occurring there, 159 die from 0 to 15; 494 from 15 to 65; and 56 from 65 and upwards, including 35 not specified. A more narrow scrutiny of the Returns, gives the following as to the various ages, relatively to sex, and the population of various ages in Middlesex, to every 10,000:—

Age.	Deaths—Male.	Population.	Deaths—Female.	Population.	Total Deaths.	Population.
0	1,103		934		2,037	
5	703		633		1,336	
10	381	303,430	317	385,025	698	748,455
15	726		650		1,376	
25	990		1,110		2,100	
35	949		1,230		2,179	
45	891		993		1,884	
55	650		834		1,484	
65	384	513,526	598	611,695	982	1,125,221
75	120		252		372	
85	9		26		35	
95	...		...		...	
?	8		6		14	

The population given above is at the periods from 0 to 20, and from 20 and upwards.

Here the chief periods of liability seem to be, *as to age*, for both sexes, at 0, 25, 35, 45, and, as respects females, 55; and the ages of 10, 75, and 85, the least liable; as it respects males, the deaths are above those of females at the ages of 0, 5, 10, and 15, from which latter period, the deaths of females invariably preponderate, with the differences respectively of 120, 281, 102, 184, 214, 132, and 17.

By the deaths at each age, however, *according to population*, the following is the result:—

1 Male dies in 106·6 under 20 years of age
1 " " in 146·8 above 20 " " and upwards.
1 Female " in 124·6 under 20 " "
1 " " in 136·3 above 20 " " and upwards.
1 of Both Sexes " in 115·2 under 20 " "
1 " " in 140·9 above 20 " " and upwards.

So that the liability would hence appear to be as follows:—1st. Males under 20 years of age; 2nd. Both sexes under 20; 3rd. Females under 20; 4th. Females above 20 and upwards; 5th. Both sexes above 20 and upwards; and 6th. Males above 20 and upwards.

III. TRADE OR POSITION.

Of 1000 deaths by cholera, 280 were men, 331 women, 209 boys, and 180 girls. Of the women,

in this number, 116 were wives, 82 widows, and 30 spinsters; and of the others not so classed, 11 were servants, 8 prisoners, 4 dressmakers, 4 laundresses, 3 ladies, 3 paupers, and the other 18 are distributed among 8 occupations. Among the men, the highest numbers to any one class are respectively—41 labourers, 18 mariners, 13 carpenters, 12 shoemakers, 9 tailors, 9 weavers, 7 pensioners, 7 clerks, 6 porters, and 3 gentlemen; leaving 155 deaths to be apportioned to 95 occupations, or 1·6 to each. Of the wives, the highest numbers are among those whose husbands were labourers and shoemakers (31 and 9 respectively); and of the children, 39 are the sons of labourers, and 33 the daughters of such, the highest numbers as it respects children standing in equal ratios to those of the men; from all which it appears that labourers, mariners, carpenters, and shoemakers are the occupations peculiarly marked by the disease, so far as statistics go. But we must look at it in another light, viz., as compared with the relative population of each description. It is as follows:—

Description.	Number of Deaths by Cholera	Number living of each Description in England, in 1841.
	in 1000	
Men	280	3,897,336
Women	331	4,223,780
Boys	209	3,430,181
Girls	180	3,448,857
FEMALES.		
Servants	11	712,493
Prisoners	8	9,865
Dressmakers	4	80,079
Laundresses	4	45,019
Paupers	3	69,810
Ladies	3	303,583
MALES.		
Labourers	41	307,535
Mariners	18	288,630
Carpenters	13	127,804
Shoemakers	12	165,881
Tailors	9	96,112
Weavers	9	58,991
Pensioners	7	21,349
Clerks	7	47,732
Porters	6	23,891
Gentlemen	3	118,412
All Occupations, to October 20	14,538	7,094,186

The general point here indicated is, that occupation has little to do with exposing to the attack of cholera.

IV. DURATION OF ATTACK.

It appears that of all the deaths, 212 take place within one hour, 6651 under 1 day, 2461 in one day, 1045 in 2 days, 306 in 7 days, and 7 in 28 days from the period of attack. As it respects males and females the duration of attack to death stands as follows:—

Period.	Males.	Females.	Total.
0 hour	136	76	212
6 ,,	950	809	1,758
12 ,,	1,575	1,661	3,236
18 ,,	636	809	1,445
Total under 1 day	3,297	3,354	6,651
1 day	1,109	1,352	2,461
2 ,,	486	559	1,045
3 ,,	386	438	824
4 ,,	244	269	513
5 ,,	207	195	402
6 ,,	104	118	222
7 ,,	139	167	306
8 ,,	45	65	110
9 ,,	30	39	69
10 ,,	72	106	178
14 ,,	43	70	113
21 ,,	12	21	33
28 ,,	4	3	7
? ,,	736	827	1,563

Hence it follows, that from 12 hours to 4 days, and from 6 days to 21, more females die than males, and that the period when most deaths occur is in 12 hours, the least in one day; while the number (153) living it out till 14, 21, and 28 days, would be very remarkable, only that it is probable the consecutive fever must have been included, when they are stated as deaths from cholera.

SOUTH SIDE OF THE RIVER.

Notes to the foregoing Diagram.

* The City of London, within and without the walls, is divided into three Unions for the Relief of the Poor, making three Registration Districts—the City, the West, and the East. Bartholomew's Hospital is in the West District. The 65 and 146 include the Deaths in St. Bartholomew's, into which many of the Patients are brought from other parts, as well as from the West London District.

† Including the Deaths in St. Thomas's Hospital, the Mortality from Cholera in St. Olave was 179.

The Deaths of several children who were removed from Mr. Drouet's Establishment at Tooting, in the Wandsworth District, occurred and were registered in other Districts of London. The Deaths from Cholera in St. Luke's Workhouse have been transferred from the Shoreditch District to St. Luke's District in the calculations.

V. DISTRICT OR LOCALITY.

In the West District of London there have been 1249 deaths, being 1 in 277 of the population; in in the North, 957, or 1 in 473 of the population; in the Central, 1727, or 1 in 222; in the East, 3182, or 1 in 140; and in the South, 7382, or 1 in 78 of the population.

It may be interesting to compare these results with the rate of mortality from all causes in 1848, in the several Districts above-mentioned, with their population and areas in square miles:—

Districts.	Area in Square Miles.	Population Enumerated in 1841.	Rate of Deaths from All Causes in 1848.	Rate of Deaths from Cholera in 1849, according to Enumerated Population for the same year.
			1 in	1 in
West District.	17·2	301189	37	277
North ,, ..	20·5	376568	46	473
Central ,, ...	2·8	374199	38	222
East ,, ...	8 8	393067	30	140
South ,, ...	66·2	503346	32	78
London	111·5	1918369	33	152

So that with respect to all diseases, in 1848, the best District as to health is the Central, and then follow respectively, the West, the North, the South, and the East; while, as to cholera, they would stand in this order,—the North best, then, the West, the Central, the East, and the South.

Of the sub-districts comprised under the above, the following is a statement of the population in each, between parenthesis ( ), and the number of deaths from cholera in the 54 weeks:—

West Districts. — Kensington (98,320) 266; Chelsea (48,392) 264; St. George, Hanover square (74,533) 131; Westminster (62,881) 444; St. Martin in the Fields (25,049) 86; St. James, Westminster (37,331) 58.

North Districts.—Marylebone (151,706) 257; Hampstead (11,457) 9; Pancras (154,152) 352; Islington (76,919) 194; Hackney (50,214) 145.

Central Districts. — St. Giles (54,199) 279; Strand (43,524) 158; Holborn (44,386) 160; Clerkenwell (65,725) 124; St. Luke (51,874) 187; East London (39,588) 180; West London (29,092) 430; London City (55,825) 209.

East Districts. — Shoreditch (96,272) 786; Bethnal Green (85,109) 798; Whitechapel (77,199) 543; St. George-in-the East (43,142) 206; Stepney (107,408) 520; Poplar (36,729) 329.

South Districts.—St. Saviour (32,910) 545; St. Olave (19,804) 363; Bermondsey (39,672) 767; St. George, Southwark (52,004) 867; Newington, (64,137) 926; Lambeth (143,557) 1647; Wandsworth (46,054) 510; Camberwell (52,246) 530; Rotherhithe (13,894) 370; Greenwich (93,964) 760; Lewisham (26,796) 97.

In contemplating of the causes giving rise to such a diversity of rates of mortality in districts comprised within an area of 115 square miles, one cannot help being struck with the difference of elevation as being one of those causes, in the specification of which we meet with less of exception to it as a rule than with respect to almost any other phenomena attending the disease. I therefore give the diagram in the preceding page, as delineated by the Registrar-General.

The order, then, according to elevation, of the sub-districts, with the deaths from cholera, is as follows:—

	Elevation.	Deaths in 10,000.		Elevation.	Deaths in 10,000.
Hampstead ...	...	8	Lewisham ...	28	35
Marylebone ...	100	17	West London..	28	*79
Islington ...	88	25	Wandsworth...	22	76
Pancras ...	80	22	Stepney	16	47
St. Giles ...	68	51	St. George-in-the-East ...	15	46
Clerkenwell ...	63	18	Chelsea	12	53
Hackney ...	55	26	Poplar	10	86
Holborn ...	53	35	Greenwich ...	8	78

St. James, Westminster	43	15	St. Olave ...	2	†152
East London...	42	43	Bermondsey ...	0	189
London, City...	38	37	St. George, Southwark..	0	164
Bethnal-green	36	91	Rotherhithe ...	0	263
St. Martin-in-the Fields ...	35	33	Newington	2 below high water	142
St. George, Hanover-sq.	34	16			
Whitechapel...	28	67			

* Or, 146. See note to foregoing Diagram.
† Or, 179. See ditto.

Here we see that the exceptions to the rule of a high elevation being opposed to the advance of cholera, are St. Giles, Shoreditch, Bethnal green, and St. Luke's, places which, it is patent to every one, are subjected to other ill conditions which, if they were situated on Alpine ridges or Himalayan heights, would still be obnoxious to life; while the only exception to a low elevation being favourable to the dissemination of cholera, seems to be that of Westminster, a place which, though it has its dens, can yet boast of being one of the localities of the aristocracy. And I may remark here, that the south side of the Thames is not now for the first time marked as the great hotbed of pestilence, but was equally so 200 years ago. Dr. Webster says:—"In the plague of 1665, the number of deaths from this disease reported to have taken place on the Southwark side of the Thames, amounted to 11,176, although then very thinly inhabited compared to its present extent—one sixth of total deaths, with a population of one-twelfth." (a)

It is worthy of notice, that on May 26, when 5 deaths only are registered, and when it may be said to have fairly set in for its work of destruction, 2 of those deaths were registered in the west district, and the other 3 in the north, districts which have been shown to be the most free from the disease; and that of the 5 deaths, 1 occurred in Westminster, 1 in St. James's, Westminster, 2 in Marylebone, and 1 in Hackney, all, in the event, peculiarly favoured districts.

VI. METEOROLOGICAL PHENOMENA.

Thermometer.—The indications of this instrument for the 54 weeks may be seen from the diagram in p. 358, but, comparatively, we may state that the temperature has been plus of the average of seven years to the amount of 126·4° Fahr., in 32 weeks, and minus the same average to the extent of 77·2° in 22 weeks of the 54, giving a plus in the whole period of 49·2°.

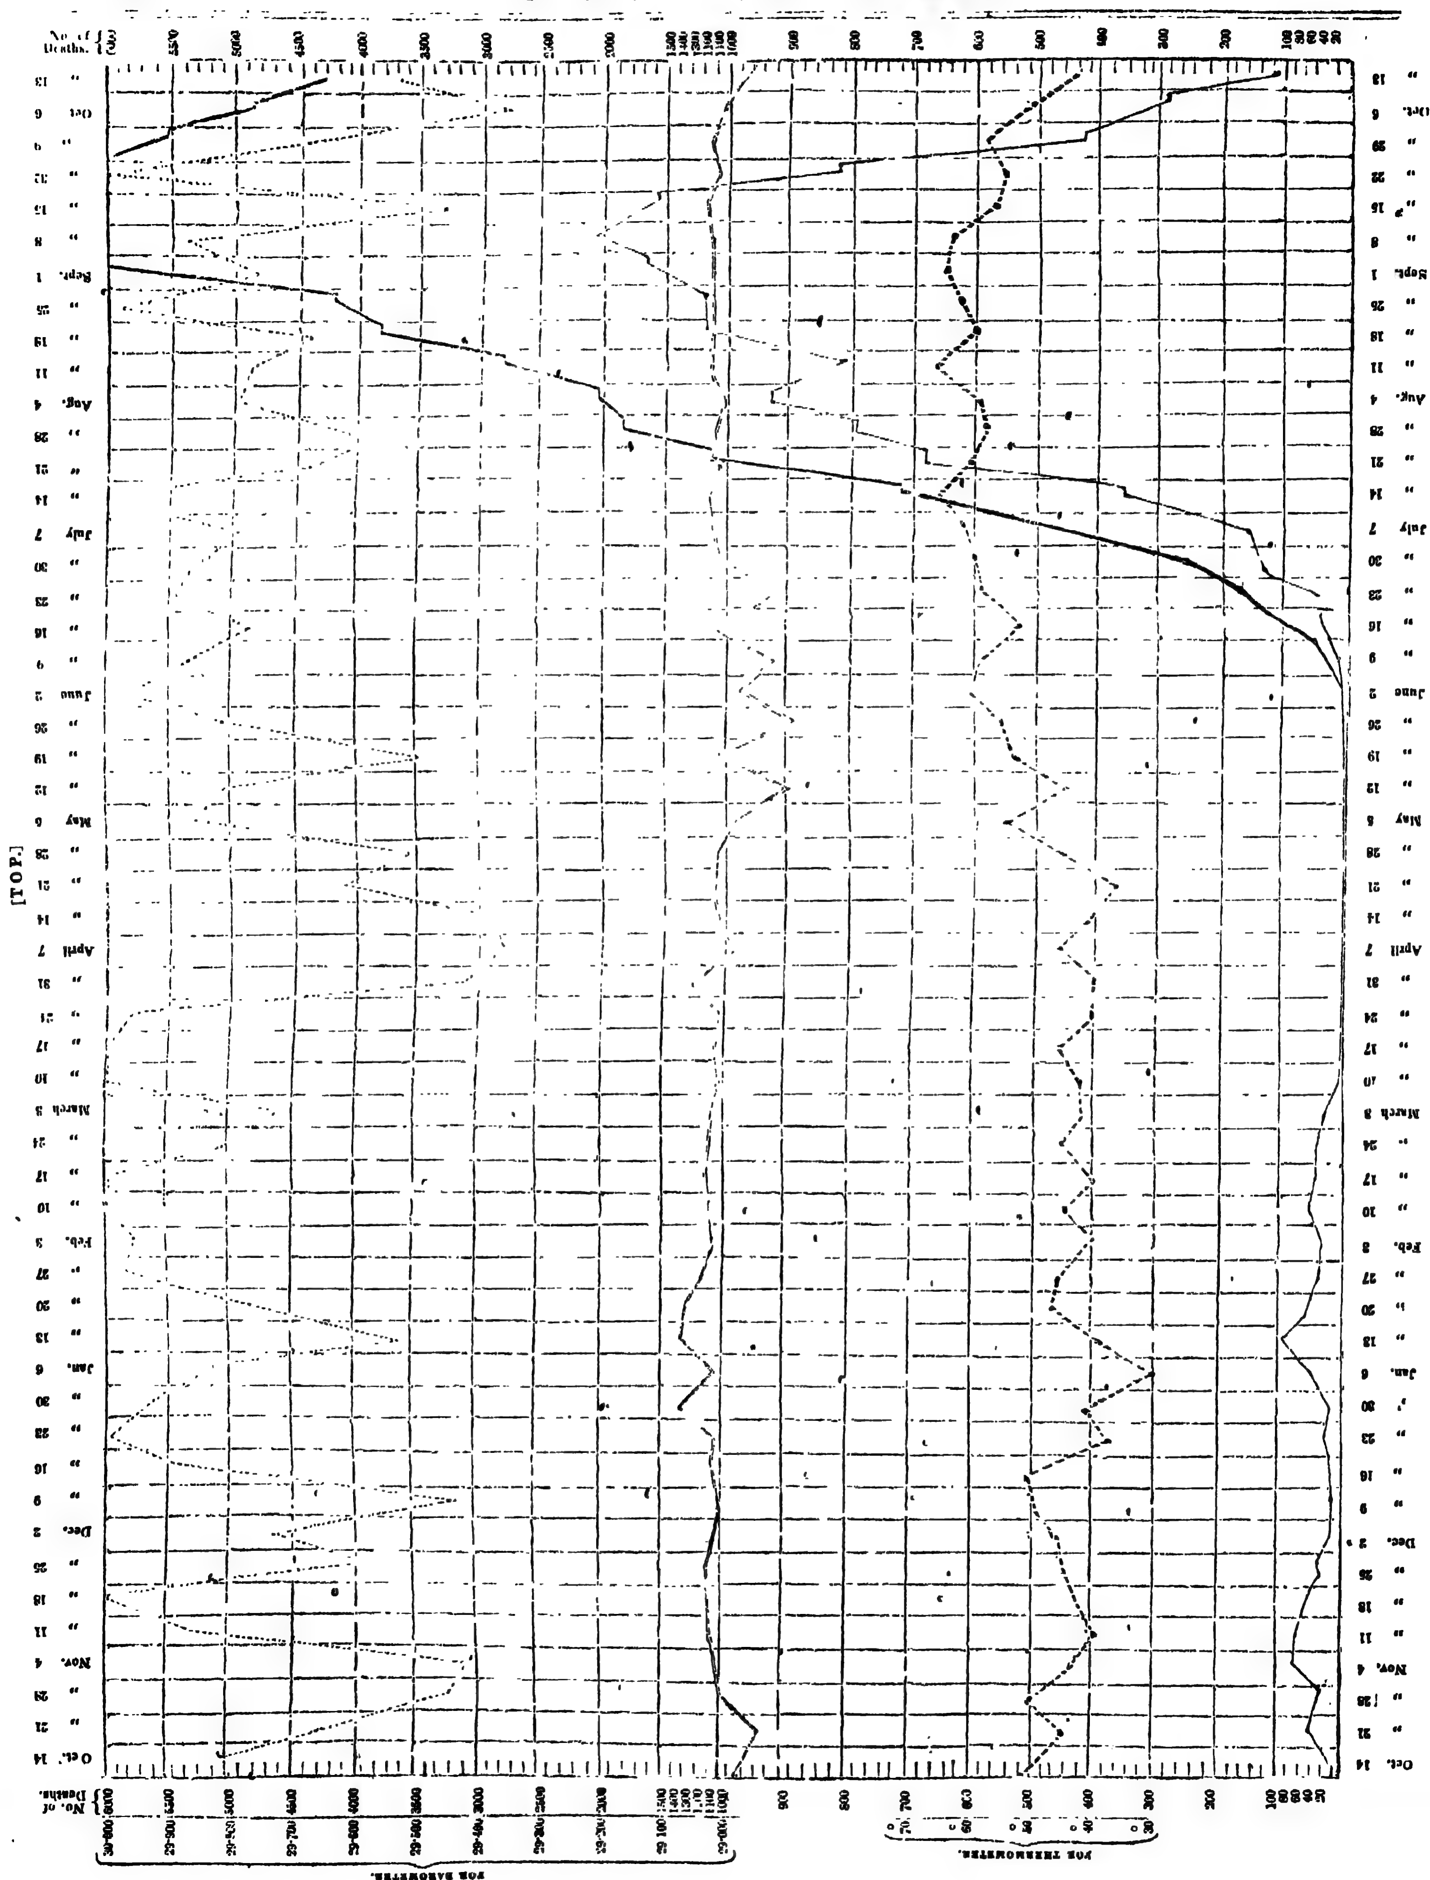
The weeks in which it was plus are as follows: —Oct. 7, 14, 28; Nov. 25; Dec. 2, 9, 16, and 30; Jan. 13, 20, and 27; Feb. 3, 10, 17, and 24; March 3, 10, and 17; April 7; May 5, 19, 26; June 2, 9, 30; July 7, 14; August 11, 25; Sept. 1, 8, 29.

The weeks in which the temperature was minus are: —Oct. 21; Nov. 4, 11, 18; Dec. 23; Jan. 6; March 24, 31; April 14, 21, 28; May 12; June 16, 23; July 21, 28; Aug. 4, 18; Sept. 15, 22; Oct. 6, 13.

Barometer.—This condition may also be seen by the Diagram, only I may remark, that the differences, which appear to be great, are rendered so through the scale being drawn out to three places of decimal parts of an inch, but which really, in such an instrument as the Barometer, indicate without much exaggeration the effect of barometric pressure.

Electricity.—In the 54 weeks, negative electricity was shown on 18 days, in the weeks ending Oct. 14, 21; Dec. 2, 9, 30; Feb. 17; April 14, 21; May 19; June 1, 30; July 21, 28; and Aug. 18. Positive electricity was shown on 147 days, in the weeks ending Oct. 7, 14, 21; Dec. 9, 16, 23, 30; Jan. 6, 13, 20, 27; Feb. 3, 10, 24; March 3, 10, 17, 21; April 14, 21, 28; May 5, 26; June 2, 9, 16, 23, 30; July 7, 28; August 4, 11, 18, 25; Sept. 1, 8, 15, 22, 29; Oct. 6, 13. Nothing was shown on 199 days, and in every week, excepting those ending Aug. 4 and Sept. 15. In the 2 weeks ending March 31 and April 7, no observations are recorded. From the week ending Sept. 28 to that of Nov. 25, nothing was shown on any day, as likewise in the weeks ending May 12 and July 14.

Rain in Inches.—During the period included in this inquiry, the amount of rain fallen has been 26·90 inches. During 6 weeks only there has been no rain indicated, viz., in those ending Feb. 17, March 17 and 24, June 23, and July 7 and 14. The largest quantity of rain fallen has been in the weeks ending Oct. 14 and 28, Nov. 4, Dec. 2, 9, and 16, March 3, April 21, May 26, June 2, July 28; Oct. 6 and 13; in which the quantity was respectively 0·81, 1·35, 0·89, 0·86, 0 74, 0·92, 1 48, 0 90, 1·37, 1·60, 2·15, 2·20, and 0·74, giving a total, in the 13 weeks, of 16 01 inches, and leaving 10·89 inches to be distributed among 41 weeks, or about 0·46 per week.



Horizontal Movement of the Air.—This occurred as follows:—

VII. SEASON OR PERIOD.

After many indications of the advance of the disease to the Metropolis, on October 7, 1848, 13 deaths from it were registered; in the next week this number rose to 30, and it then gradually advanced, until, on Nov. 4, 65 deaths had occurred; from this period it fell, till Jan. 6, when 61 deaths are given; then, on the 13th, 94; and again gradually falling, till, on April 21, the return only gives 1 death from cholera. On June 2, however, there are 9 deaths; then, the next week, 12; and from this period it advanced rapidly till, in the week ending Sept. 8 (fifteen weeks) it arrived at its maximum, 2026; then falling, however, more rapidly than it rose, so that in five weeks it numbered only 110. Thus it had been dragging along from September of 1848, waiting, like a destroying army, for the summer months, then to advance in its work of destruction till the approach of another winter should say, "Hitherto shalt thou go, but no further." To aid the reader, however, in another way to realize the course the cholera has taken in respect to season, I here give the following diagram, which exhibits at one view the course of the cholera from Oct. 14, 1848, to Oct. 13, 1849, compared with the plague of 1665, and the deaths from all causes, cholera excepted, for the same period, together with the state of the thermometer and the barometer.

FOR BAROMETER.
FOR THERMOMETER.

Explanation of the Diagram.—The *perpendicular* lines mark the period from Oct. 14, 1848, to Oct. 13, 1849, into 53 weeks. The *horizontal* lines mark numbers of deaths from 1 up to 6,000, in divisions of 100 each up to 1,000, and from thence in divisions of 500 each. These lines also serve for the barometer and thermometer, where their respective scales are placed, and according to the numbers there indicated. The *thin line* represents the course of the cholera of 1849; the *thick black* line represents that of the Plague of 1665; the *double thin* line the deaths from all causes (excepting cholera) in 1848-9; the *thick dotted* line the thermometer; and the *thin dotted* line the barometer.

I know not how to depict better the peculiarity of the cholera, so far as the number of deaths and the season of the year are concerned, than by the foregoing diagram. The plan upon which it is constructed, once understood, presents very many points of interest, not the least of which is the remarkable coincidence between the course in the cholera and that of the Plague, virulence alone excepted. Nor is this the only instance, for of the four Plagues, those of 1603, 1625, and 1665, as compared with the cholera, the same phenomenon appears. I subjoin the following Table :—

TABLE showing the NUMBER of DEATHS WEEKLY, as well of all DISEASES as of the PLAGUE, in the YEARS 1603, 1625, 1636, and 1665, and of the CHOLERA in the same weeks of 1849.

Much has been said as to the dependence to be placed on the records as to the plague, and the correctness of the old Bills of Mortality; but, from a glance at them, as here given, they seem to bear internal evidence of an approximation to the truth; and Heberden says: "The agreement of these Bills with each other does alone carry with it a strong proof, that the numbers under the several articles are by no means set down at random; and that such registers, taken together and considered on an extensive scale, must be allowed to constitute a very unexceptionable basis for medical reasoning."

It has been frequently said, that while any pestilence is raging, other diseases (especially those of the zymotic class) are found partially to succumb. The Table at the end of this Section will show how far this is borne out by facts, giving, as it does, the following result, as deducible from it :—

	1840	1841	1842	1843	1844	1845	1846	1847	1848	1849
Cholera	61		120	80	66	52	221	104	273	13554
Typhus	695		652	1235	977	662	530	1734	1974	1385
All Zymotic Diseases except Cholera	2772	2298	2644	5670	3904	4865	5393	7264	9816	8669
						or, Deduct Diarrhœa beyond the average of 5 years....			...	1779
										6890

According to this, then, the average of typhus being, for the ten years, 1,021, the deaths in 1849 were over the average by 364, but under those in the years 1847 and 1848, by 349 and 589 respectively. The average of deaths from all zymotic diseases, excepting cholera, being, in the ten years, 5,151, the deaths in 1849 were 1,739 above that average, but under the deaths in 1847 and 1848 by 374 and 2,926 respectively. It will be seen from hence, that here is no ground for the assumption, that other diseases are in check while cholera is prevalent; for, though there does appear a decrease in 1840, both as to typhus and all zymotic diseases, compared with 1847 and 1848, and that notwithstanding increase of population, yet the difference is not so much, but it may be accounted for by the fact of the cholera taking off a great number who would otherwise have been the subjects of other zymotic diseases. It is worth noting, however, the vast increase of deaths from typhus and all zymotics in the two years previously to the ravages of cholera.

TABLE showing the NUMBER of DEATHS from CHOLERA, TYPHUS, and all ZYMOTIC DISEASES except CHOLERA, in the TEN YEARS 1840, 1841, 1842, 1843, 1844, 1845, 1846, 1847, 1848, 1849; and the DEATHS from ALL ZYMOTIC DISEASES in 1849, excepting Cholera and Diarrhœa, for the weeks ending April 7 to October 20.

NOTE.—C. stands for Cholera. T. for Typhus. "All" signifies all Zymotic Diseases except Cholera. In the years from 1840 to 1847 the Weekly Average is given on each Quarter's Return. In the years 1848 and 1849 the real numbers are given.

Such are the principal facts in connexion with the cholera, so far as registered statistics give them, and I need hardly add, in conclusion, that they invite, as much as they demand, most careful study. That these facts may tend to throw in any light as to the treatment of the disease, of course, is not pretended; but it remains to be shown what that disease is, in the history of which the Profession is not interested, especially as it aspires more to the character of benevolence and philanthropy, than to have their names inscribed on the rolls of fame, or to stand well on the balance-sheet of the world's commerce.

THE COMMUNICABILITY OF THE CHOLERA POISON FROM MAN TO MAN.

By ALFRED EBSWORTH, Surgeon, Basford Union.

After the *emanations* from the General Board of Health, and the broad assertions made by them, as to the non-contagiousness of cholera, I felt assured the disease was as harmless as a sucking babe; and that one might dissect a case with impunity, examine the discharges, and inhale the volatile odours of the quickly decomposing corpses with the greatest *sang froid*. The experience of the last few weeks, however, has taught me to believe their deductions as fallacious as their reports; both are on a par, equally deceptive and prejudicial to the public weal. If cholera is contagious, and the following cases go strongly to prove the point, will not a vast deal of mischief be done in families who are led to believe the contrary? The loving wife will hang imprudently over an afflicted husband. Children will come in and out of the sick chamber, and carry the plague-spot into every room and bed in the house. Neighbours will take charge of a child, and so induct the poison into their own kind breasts: in fact, I am convinced, the more you propagate a theory adverse to the truth, the more mischief must accrue in the long run to the believers in it.

Cholera is epidemic, but it is also *contagious* and *infectious*—a bad locality attracting the poison to the inhabitants—and the inhabitants themselves being leavened by a little leaven, if of fungoid origin, (which I greatly doubt, notwithstanding the high note of the tin trumpet,) the fungus *spreads like bricks* (of mushroom spawn) and brings forth fruit in every hot-bed it may find. But to my cases:—

Robert Stainforth, residing in an isolated house,—a clear, constant brook of good water runs in front, and not a case of cholera has occurred within twenty miles of his residence. Hears of the illness of his son and sister at Hull, where cholera was raging. He goes and performs the last offices to each. He returns home in health and spirits, having performed his duty, and braved the complaint, and retires to bed in the enjoyment of full and perfect health to all appearances. The seed of the disorder has been brought, however, with him, and he had not been more than two hours in bed before diarrhœa begins; it becomes more violent, and I am sent for at 2 a.m. He now has awful cramps, whispering voice, feeble pulse, blue contracted surface, cold thrilling tongue, rice water deluging purging, and, in less than twenty-four hours he is gathered to his father's tomb. What is this but infection? Yes, but others in his family, who nursed him in his illness, did not take it; no, perhaps a higher Power rewarded their assiduity and tenderness, and preserved them.

William Pinket, residing in a row of six houses of an inferior description is attacked, and dies in a few hours. This is the first case in the village of Bulwell. How he took it, Heaven knows! Now, mark the progress of the disorder. His four brothers and sisters take it. The man who laid him out takes it. The next door neighbour takes the disorder into his family, after performing a similar office. Then, a child belonging to this last family, goes to sleep with a neighbour's family, and they begin in the night. Another man, residing away from all these, calls repeatedly in to assist and condole with the 2nd case; takes it in to the family, and two of his children are the victims. Or, taking the houses as 1, 2, 3, 4, 5, 6, and 7, in a different situation: we find the disease breaking out at 3, the disease is propagated to 1 and 4, who laid the body out, and carried it to the grave. No. 4 sends a child also to No. 1, and the members of the family who sleep in the chamber with it are infected. No. 7 comes in to No. 4, to perform charitable offices, takes the disease home in his clothes, gives it to his family, two of whom die very speedily. And, again, a man passing by the above houses daily to his dinner, takes the disorder into his family, and his grandmother falls. Here we have instances both of virulent contagion, and a very probable case of infection. The above facts only serve to confirm much what others have written and observed upon; and the inferences I have drawn from them is in my practice to lay down rules to the families I attend, to beware of everything which will tend to propagate the disorder—to have straw beds which can be burnt, old sheets and blankets which will not harm in the bleach-tub, and, above all, to smother, as far as possible, those feelings which tend to depress the spirit, and prompt to inhale the poisoned breath of a child or parent unnecessarily

I can add nothing to the true treatment of cholera patients. I believe we are on a wrong scent, and very far from home. I am, however, convinced that chloroform, applied externally to the abdomen, calves of the legs, and all the muscles affected with cramp, is a most invaluable anti-spasmodic; it must be used very freely externally, very sparingly internally, as it produces a determination to the brain during the re-action, which is troublesome to treat. I write these hasty remarks, put together during an hour's respite from arduous, ill-paid, apparently never-to-be-better-paid parochial duties.

[In reference to some of the facts detailed in the above interesting communication, we beg to call our Correspondent's attention to one or two points. It is evident that the case of Robert Stainforth proves only that a man may take cholera if he goes into a place where cholera prevails. Had any of the attendants on this man suffered, the inference might have been different. The second instance certainly seems to point to contagion; but, to make the evidence at all stringent, we require fuller particulars. We ought to know what is the population of the village, how many died, whether many were dying at the time these cases occurred, which were supposed to be traced to intercourse, but which possibly may have been owing, for anything we know, to the influence of a generally diffused cholera poison? If these were the *only* cases in a town of any size, and if the six houses referred to presented no unusual conditions which might locate cholera, our Correspondent's opinions would be strengthened. But we think he is rather inclined to believe, on slight evidence, when he traces the death of a man to the importation of poison in the clothes of a person who had merely passed the houses in question. After all, the *first* case is the important one. How did *this* originate?—Ed *Med. Times.*]

CASE OF PLACENTA PRÆVIA.

By W. F. VIDAL, M.R.C.S., Aveley, Essex, late House Surgeon to the London Hospital.

Emma T., aged 37, wife of a waterman, a woman of a full habit, being pregnant for the ninth time, wished to be attended by me in the event of her sending, as she felt very unwell, and at the same time stated, that the previous morning, and also three times before, she had a profuse discharge of blood, the first time being about the third month of utero-gestation, which gradually ceased on lying down. I recommended quietude, the recumbent position as much as possible; there being no hæmorrhage at that time, objected to an examination per vaginam, and as she was at the full period of her time, desired, that if a similar attack returned, to send without delay.

I heard no more of the case until five days after, when I was summoned at about half-past five, a.m., to go immediately to my patient, as she was in a very low state. I promptly attended, as, from the previous losses of blood, my suspicion was a case of placental presentation. On entering the room, I found her in the semi-erect posture in the bed, with wet napkins applied to the pubis, and in a very low state; countenance pallid, pulse rapid and extremely feeble; the bed, &c., was saturated with blood. On inquiry, I learnt that she had an attack similar to the first the same day after she had spoken to me, and also symptoms of approaching labour, both of which continued in a slight degree for three days, when the discharge ceased, the pains remaining, but less severe. On the following day, she exerted herself all day in her household duties, and felt great heaviness for sleep during the day, which increased at night; she went to bed, and, after a short time, all pains left her and she fell into a sound sleep and continued to do so until five o'clock the following morning, when she awoke with a feeling of faintness and general debility, and lying in a pool of blood, which greatly alarmed her, and immediately I was sent for. After some trouble I got her to the foot of the bed, as she dreaded to move from her position, and, on an examination per vaginam, found the thick mass of the placenta situated over the os uteri, and almost completely detached, with the exception of a small portion near the left side of the womb. The mouth of the latter dilated to an extent sufficient to allow nearly the introduction of the hand, and inclining to yield. During my examination a gush of blood took place, which immediately induced me to separate the remaining adherent portion of the after-birth, and endeavoured to find the feet of the child, which I soon managed, and, in the act of turning, a sudden return of hæmorrhage occurred, which drove the placenta, together with some clots of blood, by my arm externally; I ligatured the cord by the assistance of the nurse, deeming it might be of some object to the infant, although, from all appearances, "dead," as there was no pulsation in the cord, and a quantity of meconium passed; and also what might be expected from the small quantity of nutrition received, if one may judge from the proximity of the placenta, in this instance, being so slight to the uterus.

As soon as the operation of turning had been accomplished the woman seemed so exhausted that I thought further proceedings would have been attended with great hazard, and therefore waited for a time until she rallied, at the same time keeping my hand in the mouth of the uterus as a plug, and I gave slight stimuli; after a short time she regained her strength, pulse rose, and she expressed herself better. My wish was then to empty the uterus as soon as possible, which was done with comparatively little difficulty; after which, to my surprise, "there being no hæmorrhage at the time," she became perfectly insensible, and remained in that state for some minutes, when consciousness gradually returned, but not the power of articulation; the pulse extremely low. I ordered an egg beaten up with brandy, which seemed to have the effect of restoring, in part, the vital functions. The uterus contracted steadily and firmly, and no return of the flooding, which I attribute greatly to the syncope after the delivery. I remained some time with her, and left her as comfortable as possible after so severe a trial, and gave an anodyne mixture of tincture of opium and camphor mixture to be taken every three hours, and on visiting her in the evening, was pleased to find that she was perfectly composed, pulse tranquil, slight fever, and she had slept. My patient did well, and is now in perfect health.

My success in this case I impute to prompt and active measures, which, in one so severe, is, in my opinion, the sole hope of a favourable termination. At the same time, a constitution so good as that of my patient tends much to ultimate recovery.

PUERPERAL CONVULSIONS TREATED WITH CHLOROFORM.

By JOHN H. AGAR, M.D., Antigua.

January 3rd, 1849.—I was called in to a consultation in the case of Mrs. ——, after delivery of first child. She was seen for the first time on the morning of the 2nd, between 9 and 10 o'clock, when she complained of slight pains and bearing down, which commenced between 12 and 1 o'clock the previous night. On examination, the os was in no way dilated, and the parts were hot and dry. Pains continued increasing, and with more frequency, up to 1 o'clock, p.m.; the os was then slightly dilated, and the parts somewhat moister than on previous examination. 2 o'clock, labour progressing rather slow; pains at intervals of ten minutes, but not more severe; the membranes gave way at 5 o'clock; head in pelvis; external parts very rigid; pains as usual. At 6 o'clock she was seized with a strong convulsion; venesectio ad. ℥xx., with immediate relief, the pains subsiding for an hour, when, on their return, another strong convulsion followed, venesectio ad. ℥xvi., this also with relief. 8 o'clock.—Presuming the child to be dead, and deeming it advisable not to delay delivery longer, delivered with crotchet. 9 o'clock.—Expressed herself comfortable and relieved, got an opiate, and rested well up to 6 o'clock, a.m., when convulsions returned; venesectio ad. ℥xii., chlorid. hydr. gr. x. s., sumend.; emplast. vesicat. nuc 7 o'clock.—Convulsions frequent and very severe. Rept. chlorid. hydr., and having, with a great deal of trouble, ascertained from the nurse that the patient was for days previous constipated, ordered ol. croton, gt. i., omni. secund. hor. cum. enem. assaf. c. spirt. terebinth. pro re natâ. 10 o'clock.—Head shaved, and a large blister applied; convulsions violent and frequent during the day. This is the history of the case, as given to me by her accomplished physician, Dr. Sedgwick, when I saw her at 5 o'clock, p.m., for the first time, in convulsions. Neck turgid, face livid and bloated, with frothy and bloody mucus blubbering through her lips; conjunctiva injected, pupils normal; pulse frequent and volumeless; surface cold and clammy; uterus soft and dilated; no intermission in the paroxysms, and momentary threatenings of fatal asphyxia. No time was to be lost, and to our hurried review these were symptoms, common to congestion within cranium, or reflex irritation. The absence of coma or prolonged stupor during the intermission of the paroxysm in the commencement of the attack, suggested the latter; then the question was, what's to be done? Would time permit to begin to give opium? It was decided to put her immediately under the influence of chloroform. This was effected fully in little more than a minute; in ten minutes the uterus was contracted firmly to the size of a fœtal head, though previously a tight bandage, with a cup-shaped segment of a gourd and pad, made no impression. My having occasion shortly after to leave, we agreed to keep alternate watch. On my return in two hours, Dr. Sedgwick told me she remained fully under its influence for the first forty minutes, when he had to repeat it occasionally. I then took my turn at the bedside of our patient. After an hour and ten minutes, she rolled three or four times from side to side, at the same time drawing up her knees towards abdomen suddenly, and more spasmodically than looked safe. I had not repeated the chloroform for twenty-nine minutes previously, but for the next three and a half hours she was kept fully under its influence, repeating it at intervals of from fifteen to twenty minutes. During this time she lay perfectly quiet, respiration deep, pulse full, surface warm; after this there was no repetition of inhalation. Suffice it to say, from this time the case progressed rapidly to convalescence; recollection perfect on the second day. Between chloroform and opium, in the treatment of puerperal convulsions, to which does the advantage obtain? This question suggests itself, as I have seen it, in a work justly recommended, Dr. Maunsell's "Dublin Practice of Midwifery," affirmed by the Author that he never saw a case of convulsions recover unless the bowels have been got to act. I presume he includes many who have had opium fully administered. In this case purgatives had not the desired effect, and several hours after, (ten,) all symptoms had ceased, we deemed it prudent to order to repeat enema, which acted freely, bringing away a quantity of vitiated discharge and scybalous fæces.

HOSPITAL REPORTS.

St. VINCENT'S HOSPITAL.

Margaret Egan, aged 35, in a quarrel with her husband, jumped out of a first floor window into an area; after which she suffered several falls in repeated attempts to get up. The right side of the cheek was contused and swollen. Some of the front teeth knocked out. There was fracture of the left radius at its carpal extremity, and of the inferior maxilla; and she complained of pain about the right hip, which, on examination, presented the following appearances. The whole of the dorsum of the right ileum presented a remarkable fulness, from this point the right thigh in descending was inverted, and the knee showed a shortening to the amount of about three inches. On placing the two limbs together, this shortening was equally perceptible at the ancles. On reference to the spinous processes of the ileum on each side, it was found that about three quarters of an inch of the shortening alluded to could be accounted for by obliquity of the pelvis, the right side of which lay on a plane higher than the left. When she was placed as nearly as possible in the straight position, and extension of the affected limb was made, the latter and the pelvis could be drawn down so far as to remove that amount of the shortening that depended on obliquity of the pelvis. When further extension was attempted, the two ancles were brought nearly on a level with each other, but a second reference to the pelvis showed that this was occasioned by a forcible descent of the ileum on the injured side, bringing it lower than the other. When the extension was omitted, the pelvis was returned to its place, and the shortening appeared as before. On attempting to rotate out wards the strongly inverted foot, it was found that considerable mobility of the limb existed; the limb could be everted to a point that brought the toes in a line with the leg, and even a little beyond it; but complete eversion was impossible. The pain occasioned by the manipulation was considerable, but not so great as that usually produced in fracture of the neck of the femur, and no crepitus could be detected. When the hand was placed over the ileum, with a view to examine the trochanter, this prominence could be felt a little higher, and more backward, than usual. But it was impossible to detect the head of the bone in the general fullness of the whole hip in this patient, who was a very fat woman. The integuments over the hip presented no mark of contusion, while the skin covering the inner condyle of the femur was cut and abraded in several places.

The diagnosis of dislocation having been made, the patient was placed lying on a mattrass on the floor, and the usual pullies having been fixed and prepared, the patient was put under the influence of chloroform, and, with the able assistance of Sir Philip Crampton, Drs. Harrison, Scriven, Macarthy, and Bellingham, the limb was reduced in less than a minute, being about twenty-two hours after the accident. The patient was totally unconscious of pain.

Remarks.—Dr. O'Ferrall stated to us, that the characteristic features of dislocation backwards into the sciatic notch, were curiously blended with some of those which are met with in impacted fracture of the neck of the femur. There was a remarkable degree of mobility when the limb was rotated outwards; and although the hand laid over the trochanter assured him that the arc of a circle described by the neck of the bone, was equal to its whole length in the normal state, and that, consequently, no complete separation of the neck and shaft could have existed, it still remained a question, whether this movement might not be the result of an impacted fracture. This supposition would be naturally suggested by the mobility alluded to, which was greater than that usually observed in dislocation into the sciatic notch, and which existed in a degree quite incompatible with a dislocation upwards and backwards on the dorsum of the ileum. However, the age of the patient, and the impossibility of complete eversion, led to the conclusion that luxation did exist. Assuming, then, that it was a dislocation, the diagnosis lay between dislocation on the dorsum and that into the sciatic notch. The mobility of the limb was in favour of the opinion that the head of the bone lay in the sciatic notch, while the great shortening seemed to belong to displacement on the dorsum of the ileum. Dr. O'Ferrall is of opinion that, in estimating the evidence on this point, regard should be had to the sex of the individual. If we examine the skeleton of a female, we shall find that the relative position of the acetabulum and the sciatic notch differs considerably from that which occurs in the male, the angle made by the sacrum and pelvis in the female, with the vertical line of the spinal column, occasions the projection backwards of the pelvis in such a degree as to raise the sciatic notch nearly vertically over the acetabulum. In the case of the male, the displacement would be backwards, and a little upwards, while in the female it would be nearly directly upwards. This anatomical fact reconciles, then, the remarkable shortening which, in a male patient, must inevitably belong to dislocation on the dorsum of the ileum, with the equally remarkable mobility, which could not be present in that case.

The value of the fixed points afforded by the spines of the ileum, when estimating the degree of shortening of the limb, is unquestionable. But it will be seen, by reference to this case, that during the examination the pelvis must be examined from time to time, in order to avoid the error of supposing that the limb admitted of reduction by extension to its normal length, an error which might lead to the supposition of simple fracture. The apparent removal of the shortening may be, as in the present instance, owing to the drawing down of the pelvis at the side at which extension was made.

In making the diagnosis, in this case, regard was of course had to the comparative youth of the patient, to the absence of any marks of contusion on the hip, and to the laceration of the integuments over the inner condyle, the latter pointing out the part to which the force had been applied.

PROGRESS OF MEDICAL SCIENCE.

GERMANY.

ON THE GENERIC IMPORT AND DEVELOPMENT OF THE UPPER GERMINAL LAYER IN THE OVUM OF VERTEBRATE ANIMALS.

(*B. Remak in Muller's Archiv. Heft II.* 1849.)

In the communication to the Berlin Academy, from which the following is translated, the Author states that he has long wished to discover the genetic import of the upper germinal layer. In the summer of 1848 he obtained a solution of the question.

When the scutiform thickening of the germinal disc appears (the "embryonalschild" of Baer,) three definite layers may be distinguished in the germinal disc. In this thickening only the upper and the middle layers partake: the under layer being not concerned in it. This latter layer, which forms the epithelium, not only of the intestinal tube, but also that of the air-tube, the cellular parenchyma of the liver, the pancreas, the kidneys, the thyroid, and the thymus, I propose to name the *gland-layer*. The scutiform central parts of the upper and middle germinal layers grow together in their long axis. By this confluence commences the axial plate or primitive streak of Baer, from which proceed the medullary plate, the primordial vertebral plates, and the chorda. The medullary plate is thus connected with the free part of the upper germinal layer, while the primordial vertebral plates are connected with the middle layer. Both upper and middle germinal layers show a thickening, which encircles the axial structures, and is a residue of the double shield, not partaking in the

forming of the axial plate. (Wolff's "laminæ abdominalis.") The author has not been able to convince himself that a process of the free part of the upper layer covers the medullary plate.

That free portion of the upper germinal layer which limits the medullary plate is neither,—as Pander, Baer, and others interpreted it,—the foundation of the abdominal walls, ("serous or animal layer,") nor yet, as others have asserted, a transitory enveloping membrane. But it covers the embryo, and is thus *the foundation of the non-vascular and nerveless tegumentary coverings, the epidermis, the nails, the feathers, and the beak.* The peripheric part clothes the cavity of the amnion and, after the conclusion of the amnion, a process which separates itself from this, and surrounds the yolk, forms the so-called serous membrane. The name "horn-layer" (hornblatt) might best serve for this part of the upper germinal layer, which takes no share in the axial structures.

During the third day of incubation, the costal plates separate from that thickened portion of the middle germinal layer which defines the primordial vertebral plates; they are then apposed to a correspondingly thickened part of the horn-layer, so as to give rise to the cavity of the belly. The horn-layer thus loses its individuality, and becomes a covering of the costal plates. The limbs which spring from these latter, in growing, carry before them this covering. Even at the seventh day, a considerable thickening may be seen at the free ends of the hinder extremities, corresponding to the foundation of the nails.

It is not difficult to follow, throughout, the metamorphosis of the horn-layer into feathers, nails, and epidermis.

The feathers first appear as wart-shaped excrescences of the skin, which forthwith take a tufty or hairy appearance. Every such excrescence consists of a soft bolster, which is formed of cells, contains loops of blood-vessels, and is covered by a solid and proportionally thick covering derived from the horn-layer. On treating this latter with water, cells may be recognised on its outer surface. When the excrescence becomes longer, the horny covering acquires a disproportionate thickness. At the tenth day, this covering offers a singular contrast between an inner, solid, and opaque layer, which consists of columns projecting from the vascular axial space, and an outer transparent layer of cells which is loosened by water. Almost always, numerous star-shaped pigmentary figures are discernible in the inner layer; it is only in the quite white feathers that they are entirely absent. This layer, lying next to the vascular stem, is the groundwork of the feather, while, on the other hand, the outer epithelial layer is the basis of the colourless skin, on the rupture of which the coloured feathers come to light.

The commencement of the nails is similar. On the eleventh day the horn-layer is thickened on the points of the toes; and, from the twelfth day forward, one may perceive the separation of this layer into a solid horny layer of nail, and a soft, easily separable covering. Here also a very extraordinary histogenetic contrast is exhibited between the cells of the nail, and those of its tegumentary covering. In the transparent cells of the latter, which are dilatable by the action of water, the nuclei may be seen as proportionally small, solid corpuscles. While towards the sixteenth day the hardened nail-layer exhibits large, transparent, vesicular nuclei, which are surrounded by a dense, finely granular cell-content. In the horny coverings of the foot, in the beak, and in the epidermis generally, the same separation of the horn-layer into two strata may be discerned.

Since the sweat-glands and sebaceous follicles of the mammalian skin are absent from birds, and research on the glands of the rump has hitherto afforded little result, it will require a comparison with the mammalian embryo to decide whether the horn-layer partakes in the development of the cutaneous glands, and is thus, in this additional respect, comparable with the gland-layer of the intestinal tube. (Here a foot-note by the author states, that, in the embryo of the pig, he has seen the sebaceous glands produced from the tubular hair-germs, which are in their turn developed from the deep, pigmentary part of the horn-layer.) But, in any case, these observations now communicated exhibit a novel and surprisingly simple law of development for the higher vertebrata—to wit, a middle layer which developes the nerves and vessels; a central nervous system; and two non-vascular and nerveless outer layers.

[We beg to call the especial attention of our readers to this interesting paper. It appears very probable, that we may look for further researches and observations from the Author on this subject but, even as at present described, there is here much that is both new and worthy of very careful consideration. In future observations there is one question that seems to us of great moment; viz., to which of the layers is the formation of the basement membrane to be allotted. Is it, as research and analogy would hitherto indicate, a confluence of the cells of the horn and mucous layers: or is it referrible to the vessels, and through these to the middle layer?—Ed. *Med. Times.*]

IRELAND.

(From our Dublin Correspondent.)

THE SCHOOLS OF DUBLIN—REDUCTION OF FEES—ALBERT UNIVERSITY.

The newspapers published here on the morning of the 27th of October, contain an announcement to the effect that, in consequence of the extreme depression of the times, the Professors and Lecturers connected with the various medical schools in Dublin had resolved to reduce the fees requisite for attendance on the different courses; that in the School of Physic attached to the University, the fees would in future be three guineas instead of four; and that in the other schools throughout the city, the payments required would be diminished from three guineas to two for each department. This announcement was accompanied by editorial comments as to the liberality and generosity of the course pursued.

Whatever the motives which led to this reduction, it is now an accomplished fact; and it will be well to look steadily at the consequences, which will be important not only to the medical profession in Ireland, but also to that in Great Britain.

It is questionable whether the influence of this reduction in the Dublin School will be confined to the Irish Colleges; it is likely to affect also the English and Scotch Schools of Medicine. In future, gentlemen will be enabled to go through the necessary exercises for examination at the London College of Surgeons and Apothecaries' Hall more cheaply in Dublin than in any other part of the United Empire. Students and their friends will not be long before they discover this; and, to protect themselves, the Schools in London and the provinces will have either to come down to the Dublin standard, or to promote such a Bill for Medical reform, as will render competition of this nature, for the future, impossible.

The importance of this change, however, becomes still greater when it is considered in connexion with the institution of an Albert University in Dublin. It is now nearly certain, that it is intended to form an University in the Metropolis of Ireland, on principles analogous to those of the London University.

The Albert University is to be in Ireland, the University of united education, without distinction of creeds, and wherever this education is obtained it will be recognised. The Dublin School of Medicine will, therefore, stand towards this University in precisely the same relation as the Schools of Cork, Galway, or Belfast. The Board of Colleges have, however, endeavoured to obviate this by the expedient, which we had believed deservedly obsolete, of compelling attendance for one session at either of the provincial Schools. We may be sure that the Albert University will act towards the Queen's Colleges just as the London University does towards King's and University Colleges. If these premises prove correct, Dublin will be the seat of the cheapest Medical School, and the cheapest and most accessible University in the United Empire. How will these things affect the Scotch and London Universities? These are considerations which may very much alter the future relations of medical education.

Lastly, how will these increased facilities of entering the Medical Profession affect the respectability of the Profession and the interests of existing practitioners? These are questions of great importance, but are too complex and intricate to be disposed of in this Article.

Complaints having reached us of the irregular delivery of the Medical Times *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the Medical Times, *147, Strand."*

THE MEDICAL TIMES.

SATURDAY, NOVEMBER 3, 1849.

Two important investigations have recently taken place, arising out of the visitation of cholera—the one, by a Committee of the College of Physicians, the other by the Commissioner of Police. The former was instituted for the purpose of ascertaining if certain fungi, said to exist only in the stools of cholera patients, and in the air and water of infected localities, really had a being; the latter to discover the actual condition of the dwelling-places of a large number of the inhabitants of this metropolis. The Physicians have, according to their printed statement, exposed a great fallacy; the Police have ascertained and published a great fact. The one has conferred a boon upon the scientific world; the other on society in general. The statement having been made, that certain living organisms, only discernible by a careful use of the microscope, were really the cause of so frightful a disease as cholera,—the actual forms of those organisms having been portrayed and published,—the duty became imperative on the first Medical Corporation of this kingdom to verify or nullify the assertion. The College could command the services of the most eminent microscopists—men whose practised eye and profound knowledge of the various living structures rendered them peculiarly qualified for exposing error, or for establishing truth.

Whatever might be the decision at which they arrived, it would go forth to the world with an authority and an influence which the most eminent private individual would fail to command. The College, therefore, by appointing such a Committee, has discharged a duty it owed to itself, to the Medical Profession, and to the public; and we fear the an-

nouncement of this Committee will leave only to the Bristol microscopists the fame of having mistaken substances without vitality for living forms.

It is not for us to say how far medicine would have been benefited if "cholera fungi" had been found to exist. The discovery would certainly have increased the knowledge of the physician, if it had not enabled him to treat the disease with more success—it might have added to the "curiosities of science" without conferring a single benefit on therapeutics—it might have exhibited the indomitable spirit of research which animates the cultivators of medicine, and have left the healing art itself as helpless as before. We speak thus doubtingly because we know that nearly all the Pharmacopœias of the world have been ransacked for remedies with but a small amount of success. Experience has proved that cholera must be combated by other means than those which curative medicine has at its command. This to the modern physician, who has but partially cultivated the science of hygiene, is a very humbling fact; but one which, once taking root in his mind, will spring up and bear fruit which shall be for "the healing of the nations."

The investigations of the Commissioner of Police we now cite, to establish the truth of our assertion. The sergeants of the force, we are informed, reported on the state of 15,010 houses in the metropolis of the *civilized* world. Of this number no less than 12,878 appear as "whited sepulchres," fair in their external aspects, but containing within the elements of disease and death. We are astonished and appalled at the fearful relation in reference to houses whose walls and floors are blackened by the accumulation of dirt—whose air is contaminated by deleterious exhalations from badly constructed drains and gorged cesspools—whose cisterns are stagnant receptacles of a fluid, holding in solution animal and vegetable matters of the most disgusting kind, supplied by "Companies" as pure water—whose cellars are loaded with filth and rubbish, and whose passages are flanked by offensive cloacæ. These are things unobserved by the traveller without, and unheeded by the inhabitant within, but which are injurious to health and the *avant courriers* of death.

We would not have it supposed that the Commissioner of Police have given the sum total of all the nuisances of London in their report; it contains hardly a tithe of them. There are thousands of houses whose wretched external aspects bespeak their condition within; and avarice would have the cry of humanity die away unheeded. Our river, our sewers, our factories, our burial-grounds, our water companies, our houses, are all exerting an influence to perpetuate the existence of cholera, and other direful diseases. Does not the cost of maintaining such a state of things demand their speedy removal? And do not the claims of medical science strongly support such a demand? Physicians are frequently baffled in their attempts to prevent or remove disease, and it is no matter of surprise when they have so many causes in operation to resist their efforts.

As the College of Physicians has disposed of the "fungoid theory," we hope it will now address itself to the great subject of hygiene. It is certainly not beneath the notice of so learned a body, and the discoveries of the Commissioners of Police are entitled to its serious consideration.

OUR SANITARY LAWS.

It is almost a truism, that the household-life of a nation is the proper object of its ruler's study; and that political events derive their importance and significance mainly from the degree in which they, more or less, directly affect the Social condition of the people. Its almost a truism to say, that the fabric of national grandeur requires for its support a like integrity in all its social grades—that the unsoundness of a link must endanger the whole fabric—that the gangrene of the foot must involve the nobler organs—the fate of the plebeian recoil on the patrician, and the lot of the peasant trouble the repose of the king. Yet is the saying, old as it may be, pregnant with deep meaning—that the glance of the Legislator shall fall on the hovel rather than the palace, on the crowded city more than on the solitary hall.

In that remote era, while yet the hum of the populace was undrowned by the patrician murmurs of London drawing-rooms, Lord Brougham made this the theme of one of those splendid speeches, on which will hereafter rest his reputation as orator and statesman. Throwing himself into the subject with all that vehemence and concentrated vigour which marked his early career, the future aristocrat pleaded, in words full of fervour and of pathos, for that large section of the people who suffer all the ills which social organization generates, and taste but few of the compensating benefits which fall on happier citizens. Inspired by the greatness of his subject, the keen politician forgot his politics, the partisan his watchwords, and sinking the partial and the sectarian, in the universal and the national, penetrated, with the ease of genius, to the true end of Government, and to the real object for which society is formed. In words well suited to his weighty theme, the orator showed how political events are often but the consequences of social changes; and political agents often but the blind servants of that mighty current, whose ebb and flow they vainly think to sway. And in words of deep warning and of omen, he urged upon the governors of a nation, who are the physicians of its body corporate, that they should well study the vicissitudes of that imperfect fabric, should save it from the evils which might sap its health, or should seek out the remedies which could heal it.

The history of the last two years has illustrated vividly the truth of these opinions. Everywhere in Europe we have witnessed the transition of social discontent into political insurrection. More or less readily we can trace, in these wild risings of nations against their rulers, the protest which the unhappy make against their unhappiness, the uneasy against their state of pain. The politicians of the day tell us, that these terrible commotions are but the clashings of political principles, or the natural oppositions of lineage and race. But these political ties of opinion and of race are but the emblems and symbols of those deeper and more hidden wants, which those who want seek by their aid to gain. And these wants are, for the most part, coarse and physical, not intellectual and refined. The mass of men are little stirred by the abstract speculations of philosophers, although such speculations may be used for the clothing of some more tangible desires. Personal discomfort and religion are, in these days, the potent spirits which can raise the masses of the world.

In this country, such is peculiarly the case. We owe our late freedom from tumult and social disorganization, chiefly to the comparative ease and comfort which the majority of our English population has enjoyed. The pangs of hunger are not sufficiently sharp, the differences of social position not sufficiently offensive, to urge our peasants to rebel. For with our rich soil, our matchless position, and the endless vigour of our race, we have drawn hither the riches of the world, and the courage of our fathers has long ago won for us the inheritance of personal and individual freedom.

Yet it must be said, that if we owe all to ourselves, we owe little to our Government, except in so far as it has been the administrator of established law and custom. Looking back on the last fifty years, we find the tide of human affairs incessantly rolling on, the social aspect of the country daily changing, fresh elements constantly adding themselves to our intricate civilization; and yet the Government have been invariably the last to recognise the necessity, of foreseeing and providing for the result of the progress which was going on under their eyes, and of directing into appropriate channels the issues of events. Especially has the Government of this country been careless of true social questions. How many years was it before the condition of the Factory labourers could be forced on their unwilling ears? How long was it before the irregularities and manifold hardships of the Merchant, and even of the Royal Navy, could find auditors? To how great a degree have they assisted private enterprise in that most national work of Emigration, the carrying out of which is necessary for our permanent amelioration? How long has it been before the true wants and hardships of the Poor could be represented in high quarters, and meet in those high quarters with sympathy and aid? Yet these and similar questions are of far more consequence than the most subtle deliberation as to how Spain is to be managed, or Sicily assisted, or Ionia quieted. They are of greater consequence than the creation of a batch of Peers, or the bestowal of a vacant Garter. Nay, more, they are of such consequence, that if they are not fully considered, and treated as wisely as may be, we shall, from year to year, perpetuate and permit progressively to increase the evils to which these conditions give rise, until no man can say how deeply our tranquillity and public stability may not be periled.

There is no inquiry which a Government should regard as of higher interest than that which seeks to learn the common, household, daily life of the poor. In what manner do its poor live--how much of happiness and of physical comfort falls to their share—what is their ave-

rage condition of bodily health—what is their moral and intellectual standard? As the poor are without political interest, are for the most part unrepresented in the Press, and are, necessarily, in some sort, at the mercy of those who employ their labour; it is necessary continually to search out the evils which they are unable openly to express, and the neglect or oppression which they are compelled silently to bear. To protect those who cannot protect themselves, to feed those who cannot feed themselves, and to shelter those on whom the storms of Heaven must otherwise beat, are among the objects for which Providence permits Governments to be, and which Christianity imperatively demands from those who would fulfil its tenets.

That our Government has been regardless of many of these important duties is abundantly evident. It permitted children to be crowded into factories until the evil, by its magnitude, remedied itself. It left the youth and the factory woman at the mercy of their employer, until it was at length compelled to assert its right of protector, and to fix the hours beyond which the physical strength of the frame cannot be safely taxed. It allowed the merchant seamen to be affected by scurvy, until the reiterated remonstrances of the sufferers compelled the adoption of those simple rules which in the Royal Navy had been found so efficacious. It disregarded the rapid growth of our large commercial towns, and the natural consequences of the hasty assemblage of masses of men, until the remonstrances of those who knew the inevitable effects of transgressing the most obvious laws of health and life, were seconded by the approaches of pestilence, and the murmurs of a terrified people.

Owing to this want of foresight, we must attribute the fact, that in spite of our numerous advantages; in spite of the efforts of a race above all others industrious and patient, in spite of a political status, which in some respects could not be improved—the condition of the poor in this rich and powerful country, is, despite the rhetoric of historians, no better than was the state of the labouring population three centuries ago. Or, if in some respects improved; if, notwithstanding our deficiencies, the air of heaven does blow more purely upon the inhabitant of Bethnal-green than on the citizen of the old Metropolis; if the polluted water of the Thames is yet more wholesome than the water of the stagnant marshes which formerly engirdled London; if the stench from our factories and cesspools, is less intense than the odour which steamed up from the filthy habitations of our forefathers, with the floors covered with the never-shifted rushes, still no one can deny that the improvement has been by no means commensurate with the progress of an age unusually fertile in mechanical appliances, and gifted with an unprecedented control over many of the forces and powers of Nature. Is it not wonderful, that while our mechanical achievements are almost incredible, while we imitate with electric flash the light of the sun, while we emulate the wind with our steam, and print in one day what Caxton would have accomplished in a lifetime, it should still be possible to draw a comparison between the condition of our labouring class, and of the paupers in the days of Elizabeth?

Nay, more than this; when we glance over the Reports, of Sanitary Commissioners, of inquirers, into infant mortality, or into the health of towns, when we peruse the striking figures of Registrars-General, a more startling comparison cannot fail to arise. When Mr. Simon, in his vivid pictures, strives to bring to the obtuse ears of Common Councilmen the miserable state of the poor in the city of London, or Mr. D. W. Harvey classifies in regular array the nuisances of its 15,000 houses, the student of history cannot but recall those terrible portraits of social discrepancy and distress, which Ammianus Marcellinus, rudely but indelibly, traced at Rome, in the fourth century after Christ. We seem to read again the story of the 42,000 miserable habitations and the 1,800 palaces, of the daily drudgery and the life-long *fête*, of the grinding poverty and the marvellous wealth. We ask ourselves what strange resemblance thus recalls to the Englishman of the nineteenth century the woes and anguish of the Imperial City, with famine in its walls, and the Goth marching to its gates? But a moment's reflection re-assures us; we perceive that the comparison rests but on a single feature, viz., the common suffering. *We* endure evils, it is true; but they are those of neglect, and not of decay; *our* poor suffer, it may be; but the rich are not devoid of sympathy, and do not refuse to extend the rights of citizenship to all. *We* have, thank God, no luxurious patricians, who, from their chariots of silver, or from the midst of their eternal banquets, can throw no glance of pity on the perishing plebeian. On the contrary, we have an active and sympathizing middle class, and an earnest and powerful Press, who are not slow to urge the redress of all wrongs, whether they affect the poor or the rich, the peasant or the peer.

It is the duty, and has been, indeed, the attempt, of this middle class, and of the Press they instigate, to force upon the Government of this country, now as heretofore unwilling to initiate improvement, and ever waiting till the pressure from without forces them onwards, a knowledge of the wants of the poor, and a conviction that provision must at once be made for them. These efforts have been partly successful. The great question of public health has been put before the nation; its infinite ramifications, its all important bearings on the welfare of the community, have been duly acknowledged by the rulers of the State. The State has notified that the poor man is not to be deprived of the conditions of health, of pure air, of good water, of food as wholesome as may be, of the means of personal cleanliness, and of the guides to moral order and intellectual improvement.

So far is well. But the same want of legislative foresight, which permitted the accumulation of the evils, appears likely to impede their removal. Our Government proceeded to this labour of Hercules with the crudest measures and the most imperfect instruments. In the first place, they begged as a boon from opponents a portion of that which they should wholly have demanded as a right. They then crippled their own powers by a careless framing of the legislative expression of their intentions. Finally, they have now risked the whole working of their Public Health Acts by dividing the administration into sections which have no unison and no sympathy with each other, but which, on the contrary, must come into constant collision and disagreement.

Yet, if the public fairly comprehended this question, it is not yet too late to neutralize the evils. In order that it may be comprehended, we shall, in our next Number, take occasion to examine into the results which may be anticipated from the present working of our sanitary laws, and to offer some suggestions as to the proper mode of carrying out Sanitary Reform.

THE LONDON UNIVERSITY AND ITS GRADUATES.

To satisfy the wants of men prevented by scruples of conscience, or other circumstances, from conforming to the regulations of Oxford or of Cambridge, an University, empowered to grant Degrees in Laws, Medicine, and Arts, was founded in the nineteenth century.

The body politic and corporate to which we refer was named "The University of London." At its creation, it was composed of a Chancellor, a Vice-Chancellor, and thirty-six Fellows, conjointly constituting the Senate. Its Charter provides that if, by death or otherwise, the number of the Fellows shall be reduced below twenty-five, the members of the Senate shall, "as soon as conveniently may be," elect twelve "fit and proper persons to be Fellows, so that the number of thirty-six Fellows of the said University may be complete, exclusive of the Chancellor and Vice-Chancellor." The Queen reserves for herself the office of Visitor, the sole right of nominating the Chancellor, and also the power of appointing any number of new Fellows. Thus the Senate may never, if it so pleases the Crown, be called on to exercise its function of self-election. The death of the Bishop of Norwich has reduced the number of Fellows to twenty-seven. An election of new Fellows, by the Crown or the Senate, may, therefore, ere long, be expected. The Graduates of the University of London, it will be observed, are no part of the body corporate. They pay the fees demanded of them, and, after examination, receive a degree. Possessed of the document by which the honour is conferred, they leave the doors of the building, and "The University," composed of aliens by education, knows them no more. By its very constitution it can hold no communication with these Graduates, because, "until incorporated, they cannot, as a body, be technically represented at all." (a) Strange that an Institution, the offspring of liberal ideas in a liberal age, should have a constitution, so far as relates to its Graduates, less liberal than that of Oxford or of Cambridge! The Graduates of the University have, during the last two years, been actively engaged in endeavouring to obtain from the Crown a new Charter, by which they may be incorporated into the University, and be empowered to exercise the function of self-government, by electing, as from death or

(a) See Graduates' Committee Report.

otherwise seats become vacant, the members of the Senate or the Fellows of the University.

A report, lately issued by the Committee elected at a general meeting of the Graduates, informs us that, contrary to what they had conceived to be their well-founded hopes, they have failed in their efforts; and their failure they attribute to the influence exerted by the Senate over the Government. Three objections may be urged to the request of the Graduates to be incorporated into the University:

1. That the body of Graduates is not yet large enough to form a constituency. To this it may be answered, that they are already more numerous than the first Fellows of the College of Surgeons. Three hundred were, in that case, considered by the governing body sufficient to constitute a constituency. There are upwards of four hundred Graduates of the University of London. Nor is there any danger of this number diminishing, as there are about seven hundred under-graduates. It appears to us, moreover, that if twenty-six members of the Senate are considered to be numerous enough to elect twelve new Fellows, then it cannot be objected that four hundred Graduates are too few to form an electoral body.

2nd. That the body of Graduates, although numerous enough, have not yet assumed such literary, scientific, or social status, as the electoral body of an University ought to occupy. But ten short years have passed since "The University of London" sprung into existence; and where are the men on whom it has conferred the honour of a degree? Have they sunk into obscurity, and been seen no more? Of the Graduates in Laws and Arts, those more intimately acquainted with their labours must speak. In praise of the Doctors of Medicine we have no need to speak, our Profession have already spoken. More than a third of the seventy-three Doctors of Medicine have been chosen to fill chairs in the largest London and Provincial Schools, or elected to discharge the duties of Physicians to important public charities. Surely, it cannot be intended by the Senate to affirm, that these men are unworthy to have a voice in the affairs of an Institution, in the well-being and in the maintenance of the honour of which they are so deeply interested. With respect to the Bachelors of Medicine the case is somewhat different. Among them, indeed, are men whose names are favourably known, wherever the branches of science to which they have devoted themselves are cultivated. But the age of the large majority scarcely permits that maturity of judgment absolutely essential, ere the functions to which they lay claim can be exercised with benefit to the University.

3rd. That, as the Government contributes 4,000*l.* a year to the support of the University, that body cannot be expected to resign all supervision over its affairs. This objection, it appears to us, would be well founded, if the Graduates had proposed that the entire management of the University should be placed in their hands; but it is of little force, when it is remembered, that they ask only for *some part* in the management. They state in the Report before us, that they have no desire to interfere with the powers of the Crown as Visitor; and these powers, our readers need not be informed, are pretty extensive. They wish also, that the present Members of the Senate appointed by the Government should retain their seats for life. Moreover, had the Government considered the powers asked for by the Graduates *too* extensive, or the age of those who have not attained the highest honours of the University too immature, (and there may be some foundation for such an opinion,) it might have pointed out to them the objectionable clauses in the draft Charter, and thus have opened the way for an amicable settlement. But, if the Government determine to be still influenced by the Senate, and the Senate, from the above or other well-founded reasons, continue to consider it inexpedient for the present to yield to the unequivocally-expressed wishes of the Graduates, then we would strongly urge on the electing body the propriety of a part of the new batch of Fellows being Graduates of the University of London. It does seem monstrous that one claim to a Fellowship of "The University of London" should be the having graduated with honours in *another* University. For our part, we cannot conceive that men, who, like Taylor and Miller, have been elected colleagues by the distinguished Professors of University and King's Colleges, are unworthy, either morally, scientifically, or socially, to act as colleagues with Ridout and Bacot, Hammick and Billing, or even to succeed Sims and Pennington.

As there are particulars in the present arrangements of the University which we think might be benefited by publicity, and advantages which have accrued to the science of medicine from its curricula, but imperfectly appreciated, we shall take an early opportunity of returning to this subject.

We cannot however defer expressing our satisfaction at the temperate, but yet manly tone in which the Report of the Graduates' Committee is couched, and the wisdom its members have displayed in firmly resisting the attempt to mix the question of admission to the College of Physicians with that of academical reform. Such firmness and unity of purpose must eventually secure for the gentlemen the Committee represent, the privileges to which they aspire.

CHOLERA COMMITTEE REPORT.

THE Report of the Cholera Committee of the College of Physicians, which we this day re-publish, is a document not needing any advice of ours to insure an attentive consideration from our readers. To us it seems a most convincing Report, and refutes on every point the hypothesis against which it is directed. We shall probably return to this subject, after we have seen what answer the defenders of the "Cholera Fungi" can make to the College Committee. We need only say now, Drs. Baly and Gull, and their coadjutors, deserve the thanks of the Profession for the trouble they have taken, and for the ability and good sense conspicuous in every line of their able Report.

DEATH OF MR. MORTON, OF UNIVERSITY COLLEGE.

IT is with most unfeigned regret that we have to announce the sudden death of Mr. Morton, one of the Surgeons to University College Hospital. Mr. Morton died on Tuesday morning, under very peculiar circumstances, having been in perfect health and at the Hospital on Monday. We understand that he got up on Tuesday morning, went down stairs and wrote some letters, and then returned again to his bed-room. An hour or two afterwards he was found dead by his servant. This sudden and unexpected event has thrown a gloom over University College, where the deceased was beloved and esteemed by every one.

REPORTS OF SOCIETIES.

THE MEDICAL SOCIETY OF KING'S COLLEGE, LONDON.

The Introductory Meeting of this Society was held in the Dining Hall of the College, on Thursday evening the 18th October, the President for the ensuing year, Professor Fergusson, occupying the chair. The attendance of members and visiters was numerous. Among them were the reverend Principal, Dr. Jelf; the Dean of the Medical Faculty, Dr. Guy; and other Medical Professors connected with the Institution.

Professor Fergusson, in opening the meeting, thanked the Society for the honour of electing him their President. He trusted that he would on this, as on every other occasion, show the deep interest he took in the welfare of the Society. According to the custom of the Society, he would not detain them long ere he introduced the gentleman who was appointed particularly to address them. He was happy to see around him members of the Society, who had highly distinguished themselves in medical science. To those gentlemen who were about to commence a career which would require all the attention and assiduity of which they were capable, he would say, that medical men could not too early practise themselves in duties to which ordinary medical education did not reach; viz., the art of expressing themselves clearly and advisedly; the knowledge of the various opinions and action characteristic of the medical intellect of this country; and those points of etiquette found to be necessary between professional men, all which they would best acquire in a large Society like the present. The man who gained the esteem of his fellow-students in such a Society would be pretty sure to do so in the still larger community of medical practitioners. He would only add, that he was zealous, as every one connected with it must be, in the interest of a Society which, from the character of its officers and supporters, would reflect honour upon the Institution with which it was connected. The President then announced that notes had been received from the reverend the Chaplain of King's College, and from Dr. Ferguson and Professors Partridge and Bowman, honorary presidents, regretting their inability to attend the meeting; and concluded by calling upon Mr. Griffith for his address.

Samuel Griffith, Esq., A.K.C., Vice-President, read an address, in which, after a few preliminary remarks, he alluded to cholera. He first drew a contrast between the present epidemic and that which occurred in 1832. In many cases the most striking difference was observable in the almost entire freedom from pain and cramps, so general in the previous epidemic, and, in its more fatal character, showing its nearer resemblance to that of India in these respects. From various cases which had come under the author's observation he had been led to conclude that the disease was, under certain conditions, contagious, and that the probable period of incubation was about 2½ to 3½ days. He detailed some cases in which a distinct period of infection had been traced, the patient being seized on the third day. He viewed cholera as specially, if not entirely selecting its victims from among those whose alimentary organs had become vitiated, and vital stamina depressed, and considered that perfectly healthy persons were very

rarely attacked by it; the main predisposing causes being—1st. Want of nourishment, excessive fatigue, hardships, &c., as shown among the poor of London and the campaigning troops in India. 2nd. Ingestion of irritating substances, such as bad food, unwholesome air, and water holding noxious matters in solution, excess of malt and spirituous liquors, &c.; cholera, like typhus, selecting those individuals who are most exposed to such influences, and those localities in which they are most concentrated. In London, there were 2½ millions of cubic feet of ordure exposed to the air, or more than 1 cubic foot per man. 3rd. Existing Diarrhœa. This was, perhaps, the most common predisposing cause. He considered that this is not properly termed a premonitory symptom of cholera itself, otherwise we ought to find two distinct kinds of diarrhœa,—the true choleraic, and that having the characters of ordinary diarrhœa. This not being the case, he thought it unphilosophic to call that a premonitory symptom of cholera, which commonly occurs without ever merging into cholera. In the cholera of India there was generally no preceding diarrhœa; yet the Author considered that the prevalence of intestinal disorder, at particular periods, indicated a connexion not the less dangerous. He supposed that rice-water secretions were present in every case of true cholera, though not always passing by the rectum, as proved by *post mortem* inspection. The circumstances attendant upon the rise, spread, and propagation of cholera, and their bearing upon the question of contagion, were then briefly adverted to. When it attacked a house it invariably ran through all the different families susceptible of its influence, and this the Author exemplified by several cases. He then alluded to Dr. W. Budd's theory of the origin and mode of propagation of cholera by microscopic fungi, and the objections thereto. He thought that, though it was doubtful whether the theory would support future investigation, it would, at least, serve better than any other for the classification of facts. With regard to the treatment, he had found calomel, in large and frequently repeated doses, most successful, accompanied, especially, by mercurial frictions, by which re-action was more rapidly induced, and with less of the mineral introduced into the system. In extreme collapse, large doses of salt and water, sufficient to produce intense vomiting, was the most certain plan of causing re-action. This effect was probably produced mechanically, mainly; perhaps, also, partly by the solution being absorbed and acting on the blood. Salines and astringents were also very useful. He considered it doubtful whether the various plans of treatment, so much lauded, did not owe the greatest part of their apparent efficacy to the diminution of the virulence of the disease in its decline. The author concluded his address with some cheering allusions to the condition, prospects, and intentions of the Society.

S. R. Pittard, Esq., in proposing a vote of thanks to Mr. Griffith, intimated that it was the intention of the Council to collect, by circular, the opinions of the many old members of the Society now practising in the country, and of their professional acquaintance, upon the question of the contagiousness of cholera, and the facts, if any, upon which those opinions are founded. One of the great objects had in view in the organization of the Society was the connexion of a great community of medical inquirers, centering in the Society, and reporting to it objects of interest in medicine. He had remarked, that country practitioners had a far better opportunity of determining the question of contagion, among their scattered population, than those in London, where the population was so much mixed up and in such close intercourse. He considered that inquiries like this were the only way by which the question could be settled. The contagiousness of small-pox, measles, &c., had been determined only by a general feeling, gradually coming on, of the whole body of medical practitioners. He hoped that all present would aid the council in this undertaking. In 1832 he received a powerful impression that cholera was contagious, and he strongly inclined to the belief that *all* contagious diseases were caused by parasitic beings. In one disease, cholera, he thought this opinion was becoming generally received. Understanding that the cholera fungus would be shown under the microscope, upon this occasion, he had brought with him some confervæ as specimens of low vegetable forms. They would be seen to be very different in appearance to the drawings made by Mr. Brittan, which did not seem to him to be those of a vegetable structure. The only things he had seen like them were very minute biliary calculi, and some microscopic sponges.

Dr. Hensley seconded the motion of Mr. Pittard, which was carried by acclamation.

Some experiments were brought before the Society by Mr. Rogers, Civil Engineer, for the purpose of proving the efficacy of peat charcoal, prepared by his plan of compression over a vacuum, as a deodorising agent. Mr. Rogers, after enumerating the various manufacturing uses to which the peat charcoal, so prepared, could be applied, especially its value, from its density and freedom from sulphur and pyroligneous acid, in the manufacture of iron, in founding, and for fuel; and after showing, from its low price, the advantage of so using it, explained to the Society his method of preparing it, and said, that, to the present meeting, the most interesting property of the peat charcoal would be its extraordinary power, and ready application, as a deodorizer and a disinfectant. For the former purpose, he used it continually in his own house, and, by placing it in all the pans and closets, obtained a perfect freedom from effluvia. In hospitals it had been objected, that by its colour it prevented proper examination of the fæces. However that might be, it effectually removes the smell. In fever, scattered over and placed about the body of the patient, it effectually removed, he considered, all danger of infection and disagreeable odour. But the best way to convince the meeting of the latter property, was to show them the effects of the granulated charcoal upon putrid exuviæ. Mr. Rogers then produced separate portions of the granulated charcoal and putrid matter, and mixed them before the meeting, all smell being perfectly removed from the latter by the process. He also showed specimens of the dense compressed charcoal and plans of his proposed method of applying the charcoal, as a deodoriser and disinfectant, to the ordinary method of town sewerage and hospital arrangement.

The Honorary Secretary read over the notices of the Society, and a numerous list of gentlemen wishing to become members.

The President, having returned the thanks of the meeting to Mr. Rogers, vacated the chair.

Mr. Griffith proposed a vote of thanks to the President. Henry Smith, Esq., seconded the motion, which was carried amid much cheering.

Mr. Fergusson returned thanks. They had already experienced the advantage of attending such meetings as this, in hearing an interesting essay from an old student, which would be no small instruction to most persons present. Another subject of great interest, Mr. Rogers's experiments, had been brought under their notice, and the results would illustrate the extreme slowness of the advance of science. That which was at one time considered, as it were, the refuse of the earth, peat moss, would, if Mr. Rogers's views were confirmed, be found to be the most valuable article, perhaps, on the globe. The talented and distinguished nobleman, Lord Ashley, who, he believed, first pointed out, in a prominent manner, its value, had remarked, that if the things said of it were found to be correct, England had within herself more of real value than the gold lands of California. In questioning Mr. Rogers to-night, he found that he (Mr. Rogers) admitted the truth of what Lord Ashley advanced concerning the properties of peat. It was said to be very useful, in preparing bog land, to burn the peat moss, since the resulting ashes were of a very fertilising quality. This had, however, he believed, yet to be proved. These remarks on peat moss would be well illustrated, by a circumstance which occurred in Scotland some time ago, where a gentleman was at vast pains and expense to clear away a surface of bog moss some 12 ft. deep, the land beneath being considered of such value as to merit the enormous outlay. The moss that encumbered the fertile surface was got rid of, in a way Mr. Rogers, he feared, would not approve of, being cast in clods into a neighbouring river, and carried down into the ocean. He doubted not, but that Mr. Rogers might obtain plenty of bog moss, on the cheapest possible terms, by application in those quarters. Mr. Fergusson concluded, by proposing the thanks of the meeting to the excellent principal of King's College, for his company that evening, which was assented to with loud cheering.

Dr. Jelf returned thanks. It was his proud office to preside over six departments of knowledge; with each he endeavoured to be impartial; but none had he greater regard for, nor interest in, than the Medical Department of King's College. The meeting then broke up.

UPON THE REMEDIAL APPLICATION OF BENUMBING COLD.

[To the Editor of the Medical Times.]

SIR,—In taking advantage of the opportunity which you so fairly offer me of replying to the extended criticism in the *Medical Times* of the 6th inst. on the new remedy which I have introduced, I would wish to be as brief as possible; for, as regards myself, I have no wish to prolong the controversy. I have been blamed for entering into this correspondence at all; but I can waive all personal considerations when intent on establishing an important medical truth; and having once engaged in the discussion, I feel myself bound to bring it to a termination. My opponent is a practised and a plausible writer; and his habitual use of the terms of logic might impress the careless reader with the notion that he is a logician, and that his conclusions are in accordance with the logical art.

I am first attacked for not bringing forward other evidence than my own for phenomena said by the critic to be "at variance with older observations." My letter of the 13th referred to this new objection, and perhaps sufficiently; I felt myself compelled, under the peculiar circumstances in which I was placed at the time of writing that letter, to grant this demand of my critic; but in addition to the remarks and the high testimonial it contained, I may now state that the fallacy in the reasoning of my opponent, which I have already more than once commented upon, and which runs through most of his arguments, is here most conspicuous I deny that the phenomena which I describe are at variance with older observations, and that other evidence was necessary than what is commonly adduced by medical writers. I deny that there had been any experience of *short* and *limited* congelation until it was used remedially, or to produce anæsthesia in surgical operations; and it would be an insult to the judgment of the reader again to insist upon the essential difference between the prolonged congelation which causes frost-bite, and the short and regulated application of extreme cold, that furnishes us with, perhaps, the most powerful, and certainly the most prompt and safe antiphlogistic anodyne remedy wherever it can be applied, which we possess. My reliance, besides, on my own observation is complete, because it respects phenomena in which no one can be deceived. If inflammation is *seen* to be *at once* checked by severe cold, and if pain *immediately* and *permanently* ceases under its influence; if, in more than 300 cases, and perhaps a thousand applications of this agent, not the slightest mischief has been produced, or greater inconvenience than a slight redness of short duration, or a slight itching, where can be the danger of mistake, or the need of corroboration? I am perfectly willing to allow, that numberless instances of mistake in the effect of remedies have occurred; the history of medicine is full of such; but these instances, I contend, differed widely in the circumstances which I have mentioned. If truth was the object of the critic's research, why did he not make the little experiment mentioned in my letter of the 22nd ult.; it costs neither much time nor much money. A pennyworth of pounded ice, mixed with half the quantity of salt, and a bit of thin silk gauze to contain the mixture, constitute the whole of the apparatus, and the best, that, in most cases, can be employed to produce remedial congelation or anæsthesia. The application of this frigorific a few seconds to the skin, or until it congeals it, will prove its safety; and, if doubts be still entertained, after the evidence which I have produced, that an application, which will immediately arrest the circulation of blood in a part, and produce local insensibility of some duration, may nevertheless be wanting in remedial efficacy, a trial of it in cases of constant occur-

rence—such as irritable and inflamed sores, pruriginous or impetigenous eruptions, headache or toothache—will satisfy the practitioner on this point, and lead him to more important uses of the agent.

The next article in the criticism is an imaginary history of the suggestion of extreme cold in cholera—which, like most imaginations of the kind, is as wide as possible from the truth. It so happens that the postscript to the letter referred to of the 19th of July, and which postscript, we are told, was written immediately "on the inspiration arising on my mind," was written fifteen days after that letter had been sent to the medical Journal containing it; and it only consisted of a compressed statement of what was previously published through another channel. But to animadvert upon the details of this history or portrait, as it is termed, would be absurd. Suffice it to say, that the fact of the internal administration of ice having been found one of the most successful modes of treating cholera, first drew my attention to [illegible] and the [illegible], having [illegible] in other affections of the stomach somewhat analagous to its condition in cholera, and being convinced that the idea of any efficacious result following the small quantities of ice usually swallowed in cholera must be a mere fallacy, these considerations led me to reflect upon what would be the probable effect of applying cold in an efficient manner. To the laboured accusation in the criticism, that I have attached undue importance to the beneficial results of this practice, in the two cases in which I had an opportunity of trying it, I think it a sufficient reply, to quote the opinion which I have expressed in the paper furnishing these practical details,—that, however severe cold may be recommended by theory or analogy, "the true value of the agent can only be determined by numerous trials."

The critic next comments upon what he affects to consider as quite a discovery to him, viz., that it is only the short and limited application of severe cold that I advocate. This qualification, he says, is satisfactory, and "if it had been all along in the author's mind, he must have taken much pains to conceal the expression of it in some corner, probably, of his pamphlet." These remarks scarcely require an answer, and yet they are a fair specimen of this criticism of the *Medical Times*. Whoever has read any of my several Essays, or communications, on benumbing cold, knows, that every page or paragraph contains something having reference to this great essential of the remedy, its short and limited application. In the several cases of inflammatory or neuralgic disease treated by congelation, and related in my pamphlet, it rarely happens that the precise period of application is not mentioned; and in the introduction to that Work there occurs this passage:—"A person exposed to intense cold in a severe winter, or high latitudes, and a person exposed in a manufactory to the fumes of mercury or arsenic, are both exposed to danger. Powerful agents are operating upon them uncontrolled. But if the intense cold be limited in duration and extent, and small quantities of the mercury or arsenic be exhibited in the form of blue pill, or Fowler's solution, instead of being hazardous to life, they will constitute valuable remedies." And the opening passage of the first communication which I sent on the subject to a contemporary medical journal, is as follows:—"Many powerful physical agents which are destructive when they act in an uncontrolled manner on the human body, become remedial when they are regulated and applied under appropriate circumstances—excessive heat," &c., &c. —*Medical Gazette*, December 1, 1848. But this is not the lowest depth of error into which our critic falls by his pretended discovery. Let me ask him what agent, natural or artificial, has ever yet been used remedially without limitation or control? And whether it is incumbent on the practitioner who tells us that he has used prussic acid, or mercury, or arsenic, or bleeding, or heat, or cold, in any specified disease, to tell us at the same time that he has used them under certain limits or conditions, in order to prevent our falling into the mistake that he employs them without regard to quantity or time? Does not the very phrase remedial use necessarily imply the regulation of such circumstances?

"The Profession at large," says the critic, "stand aghast at Dr. Arnott's statements; and without corroboration will remain incredulous." Such of the Profession, as with the critic, cannot discriminate between regulated and uncontrolled congelation, may well stand aghast; but this number must be very small. I suspect that our critic constitutes the whole. He, no doubt, would stand equally aghast at the proposal to use electricity in medicine, because persons have been killed by this agent in thunder storms. Some of the Profession may indeed be surprised to learn, that an agent which has hitherto been only known as a cause of disease, should constitute a powerful and extensively applicable remedy; but their surprise will cease upon the reflection, that such has been the history of the best remedies we possess, which were, generally, only known as poisons or as otherwise injurious, before they were employed as remedies.

After these observations follow a series of defences of certain arguments (for some he has wisely passed over, as being utterly indefensible) in the critic's first communication, which I briefly commented upon. Whether he has succeeded in his defence, the reader, if he cares about it, can judge by referring to the earlier papers. The fallacy of not discriminating between short and unlimited congelation, pervades and vitiates the whole of the arguments now referred to. I suspect, that the subscribers to the Journal will "stand aghast" at such an amount of error in their professional guide.

The next assault is in consequence of my having expressed the sentiment, that it was wrong to limit the degree of cold in remedial applications to the freezing point of water. That a critic who stands aghast at the application of extreme cold, because it does not occur to him, that it must be limited or regulated, should be "astonished" at this sentiment, is not at all to be wondered at. I have doubt, however, that his astonishment will be participated by any reader of his criticism. If a remedial agent produces only a limited amount of good in a certain dose; and if there has been no experience of its use in larger doses, (which is strictly the case in the instance in question,) what is there astonishing in the supposition that a greater dose may possess greater power and remedial efficacy. Most medicines have been given in increasing doses till the proper limit has been ascertained; and often, as in the instances of quinine, antimony, and mercury, the larger doses have not only had more powerful, but very different effects. The never-avoided fallacy of not discriminating between short and prolonged congelation, has again led the critic into this strange error. Has it not, besides, been almost established as a principle, that, in the treatment of cholera, medicines must be exhibited in larger doses than usual; as in the instances of acetate of lead and the kindred remedy nitrate of silver, used, apparently with great advantage, during the prevalence of cholera in Paris, by M. Barth, of the Salpetriere?

The criticism concludes with the statement that I assert, because it is occasionally allowable in severe cases of diseases to employ remedies in some degree hazardous, that it is allowable to administer frigorific mixtures in cholera, notwithstanding their danger. I assert, on the contrary, and very explicitly, that my use of the frigorific in analogous cases, as well as in the two cases of cholera related, had proved that this remedy is not dangerous. But, I say again, granting, (for the sake of argument,) that the exhibition of frigorific draughts in cholera was to a certain extent, dangerous, does the critic mean to imply, by his phrase of "two blacks making a white," that it is not allowable, under certain circumstances, to use severe remedies. Is the trepan, amputation, lithotomy, or the free exhibition of opium, or the practice of profuse bleeding, free from danger?

I am, Sir, your most obedient servant,

Brighton, Oct. 20, 1849. JAMES ARNOTT.

[We have printed Dr. Arnott's communication, with the exception of a few sentences of a personal character unconnected with the subject; and, passing by all extraneous matter, proceed to apply ourselves to what remains of his arguments.

The matter of fact, on which the Doctor dwells so triumphantly as a gross logical mistake on our part is the neglecting to observe, that it is not a prolonged but a short application of a zero-cold to the stomach which he recommends in cholera. Thus bad reasoning, according to Dr. Arnott, signifies a difference with him in opinion as to a point of fact. But we still differ with him as to this fact: we affirm that he nowhere, in the communications that we commented on, and which bore to be his first and only intimations regarding the use of extreme cold in cholera stated within what limits it should be kept, up to the time when we extorted a vague limitation from him What he said elsewhere, when speaking of other diseases, and of its external use in the way of experiment, we have nothing to do with. The question between Dr. Arnott and ourselves never extended beyond cholera. We never commented upon his use of benumbing cold in other diseases—we never admitted that he had proved its safety and utility in any. In proposing a zero-cold to the stomach in cholera, at a time when the pestilence was unhinging men's minds in so many localities, he was not entitled to assume the universality of his writings, and that every one who met with his proposal had read his previous papers. We blamed him for extolling in unmeasured terms of panegyric, and without any mention of precautions, a remedy against cholera he had tried imperfectly in only two cases. But, the idea of limitation is nugatory—we have admitted his plea gratuitously. Dr. Arnott, in fact, makes no real limitation up to this moment. Let any one read his pamphlet, and other numerous papers on this present hobby, and it will be seen that the whole spirit of these is to inculcate that cold, as a remedy, cannot be applied too unsparingly. What he means by limitation is, that he does not include in his encomiums on cold, any immediate proposal to send patients to winter unsheltered in Spitzbergen or Nova Zembla. In short, he thinks he limits the use of extreme cold, because he advocates its local application. When we forced him to say, that he only advocated the short application of his remedy, we sincerely believed that he had some definite ideas as to the time during which it might be safe to keep a living part at a zero-temperature. In this, it appears, we were mistaken. He will condescend to no explanation of what he means by "short," except in what he says of an experiment which can have no reference to the stomach. We find nothing to contrast with the term "short" in his lucubrations, but the period of a Spitzbergen writer. We shall quote the passage which he gives, as indicating the strictness of his limitations, and our absurdity, in assuming that he made no distinction between what he considered a remedial degree of cold, and that which will produce frost-bite. "A person exposed to intense cold in a severe winter, or high latitudes, and a person exposed in a manufactory to the fumes of mercury or arsenic, are both exposed to danger. Powerful agents are operating on them uncontrolled. But, if the intense cold be limited in duration and extent, and small quantities of the mercury or arsenic be exhibited in the form of blue pill or Fowler's solution, instead of being hazardous to life, they will constitute valuable remedies." We quote another passage—and there are many similar in his papers—to show how he carries out the idea of limitation in extent and duration:—"The question is interesting, What would be the effect of actually freezing the uterus in the state of hæmorrhage now under consideration? This could not be effected by ice, as the above gentlemen suppose, but it might be frozen by a frigorific mixture *of thirty or forty degrees lower temperature, abundantly applied.*" (a) We are disposed to infer that Dr. Arnott disbelieves that any degree of local cold can produce frost-bite. We recommend him, with as little delay as possible, to enlighten the surgical world on this subject.

We remarked before, on Dr. Arnott's frequent use of the "*ipse dixit*" as a proof. In his letter, contained in our present Number, it figures more prominently than ever. He admits, that the history of medicine is full of mistakes as to the effect of remedies; but we get nothing more than his "*ipse dixit*" in proof that there is no such danger in this case. We fear we may strive in vain to cure him of the use of this kind of evidence, it seems so natural to him.

"Chassez le naturel, il revient au galop."

The strength of this kind of "*naturel*" in his character is even amusing. He so stands upon his solitary word being taken, that he thinks it necessary to apologise for having quoted Dr. Graves, as affording his testimony to the efficacy of benumbing cold applied externally on two occasions. We assure Dr. Arnott, this is the kind of confirmatory evidence the members of the Profession are desirous to obtain. But such a plan is sadly against the grain with

(a) *Lancet*, July 21, 1849.

Dr. Arnott. He must have interdicted the interference of those friends who have so often witnessed his use of benumbing cold both internally and externally; otherwise, surely by this time some of them would have come to the rescue and backed his testimony. It is plainly, however, a point of honour with him to have his solitary word believed. This passion even leads him into a new error of logic. He charges us with a want of love of truth, because we have not made trial of benumbing cold either on our own persons or on our patients. Now, this exactly touches the point at issue between us. We say, Dr. Arnott has not afforded sufficient evidence to induce us either to employ the remedy ourselves, or to advise our readers to use it, because, for anything we yet know to the contrary, it may be productive of great mischief. We are almost tempted to complain of the Doctor's thickheadedness—apparently he cannot be made to comprehend why we should ask stronger evidence in favour of the safety of introducing snow and salt into the stomach, than for the harmlessness of applying cotton-wool to a burn. Were cotton-wool proposed at this moment, for the first time in the treatment of burns, we should proceed at once to try it on the next opportunity, without asking for more than a simple "*ipse dixit*" from Dr. Arnott, or any one else of his respectability. We wish the Doctor would try to understand, why the proposal of snow and salt lies in a different predicament. But to our charge. In asking us to make the experiment, after all the discussion that has passed between us, he is plainly guilty of a "Petitio principii." For this discussion would plainly deserve the name of vain disputation if his object were not to persuade us to the trial, and our object to resist the trial till further evidence of its safety be produced. If the Doctor succeed in persuading us to swallow some ounces of snow or pounded ice, seasoned with twice as much salt, no better evidence of its safety being afforded than he has yet supplied, we promise him, as our rustics say, to eat him without salt.

The Doctor is a great master of what logicians call the "*ignoratio elenchi.*" The original question between us referred exclusively to the application of benumbing cold to the stomach in cholera. The argument that runs through his present communication stands thus—Because he has proved the utility of a zero-cold in other diseases, therefore it is illogical in us to deny his affirmation, that such a cold is a remedy in cholera. When we compliment him on his skill in this form of thought, perhaps he will discover himself to be in the like predicament with the worthy man who found that he had been speaking prose all his life without knowing it.

As the Doctor is jealous of any of his arguments remaining unnoticed, we shall hazard a remark on what he seems to consider a flagrant instance of our deficiency in powers of reasoning. We concluded, just as naturally as logically, that a postscript written to a letter, without change of date, was written at the same time with the letter, whereas it appears, to our confusion, by the Doctor's account, that the postscript was added fourteen days after the letter. To make this discovery, it was not logic that was required, but "clairvoyance."

We are not in the least apprehensive that our readers will withdraw their confidence from us on account of Dr. Arnott's reply, or that they will stand aghast at the amount of error detected, by his showing, in their professional guide. We entertain no ill-will against the Doctor—we respect his name, and sincerely wish he may not prove in error as to the beneficial effects of benumbing cold; but, as journalists owing a duty to the Profession, we must vindicate our title freely to canvass the proofs offered in behalf of novel remedies, above all, when these may be reasonably considered to be of a dangerous character—and in a publishing age, like the present, we feel assured, that no lessons are more necessary than those which serve to determine the proper kind of evidence on which new discoveries should be listened to. Witness, in this place, the recent instance relative to the discovery of choleraic fungi, which, we believe, we were the first to disclaim, and which the Report of the Cholera Committee, given in our present Number, sets at rest. Hebdomadal medical literature, as it brings with it many advantages, so, unless very carefully directed, has some drawbacks; and, among the latter, is the too great facility it affords to the publication of rash proposals. That Journal, then, surely deserves well of the Profession, which strives, even at the risk of occasionally hurting self-love, nay, of retarding for a little the reception of truth, to preserve its page from becoming subject to the reproach of being

"Tam ficti pravique tenax, quam nuntia veri."]

MR. LAFARGUE ON CHOLERA AND ITS TREATMENT.

[To the Editor of the Medical Times.]

SIR,—While forwarding the reports of cholera cases that have fallen under my notice, I send the following remarks, which, if you think worthy, may find insertion in your excellent periodical. Previously to having personal experience in this dire disease, from what I had read and heard, I considered it in the light of excessive diarrhœa, yet a disease *sui generis*, and not contagious; therefore, my treatment accorded with such opinion, viz., calomel and opium and cretaceous mixture, combined with kino and capsicum. After seeing a number of cases, I became convinced that cholera was contagious, and that diarrhœa, however severe, and malignant cholera, were two very different and distinct diseases. Probably most of my professional brethren, especially those who have seen much of the late epidemic, are now of this opinion. Doubtless, diarrhœa predisposes an individual to contagion, by lowering the nervous energy, and thus disenabling the system to withstand the influence of the choleric poison. In my practice I have found these remedies, which we usually find so beneficial in the diarrhœas common to this country, of but little use in malignant cholera. Of the thirty-two cases reported by me, sixteen were treated with calomel and opium and cretaceous mixture, combined with capsicum, ammonia, and compound kino powder. Of these nine died and seven recovered. Thirteen were treated according to the saline method, viz., pot. chloras, sodæ sesquicarb., and sodii chloridum, without the addition of magn. sulph. Of these two died and eleven recovered. Two were treated with sol. ant. pot. tart., and laudanum. One died and one recovered. One treated with ether and laudanum died. In all these cases friction, warmth, mustard cataplasms to abdomen, were used with much advantage in some; terebinthenate enemata without benefit; and two were bled also without benefit. This table, though, of course, very limited, decidedly favours Dr. Stevens' plan; but when all the reports have been sent in and well sifted, a juster knowledge of the treatment to be adopted in malignant cholera will be attained. It has also struck me, that, at the commencement of the outbreak in this parish, nearly all the cases terminated fatally, no matter what the treatment. As the epidemic gradually abates and leaves us, but few fatal cases occur? How are we to account for this fact? Is the malarious poison, whatever it may be, gradually wearing itself out, to become extinct? Or has some change taken place in the atmosphere unfavourable to its existence?

I must confess my treatment has been somewhat empirical. Surely, the saline plan, of which, of course, from experience I entertain a very favourable opinion, does not benefit by merely resupplying the circulating fluid with water, and its lost saline particles. It seems sometimes to act too quickly for that; for, in two very severe cases, a teaspoonful of table salt in warm water, after being swallowed instantly, stopped vomiting, and a third similar dose apparently promoted the commencement of the reaction that led to recovery, and this favourable change took place ten minutes after swallowing the first dose. Much appears to remain yet undiscovered by our professional researches into the origin, pathology, and treatment of this devastating disease. Can malignant cholera generate itself or be generated in temperate climates under any favourable combination of circumstances, as filth, warmth, moisture, with peculiar atmospheric change, causing loss of power, of splanchenic, and diminished respiratory and cutaneous action? Or does it solely originate from a peculiar concentrated malarious poison, emanating from certain tropical *loci*, thence spreading its death-carrying fomites in stated directions, under favourable atmospheric conditions? These and other more important queries remain yet to be solved. I read in the *Medical Times* that the bis. of carb. has been used by Dr. Hastings with great success. What is the *rationale* of this treatment? Doubtless, if really valuable, we shall soon hear more of its remedial and curative powers in your periodical.

I am, Sir, yours sincerely,

RT. LAFARGUE.

ST. GEORGE'S HOSPITAL.

[To the Editor of the Medical Times.]

SIR,—"A Student of St. George's Hospital" has, in your periodical, complained of "not being permitted to examine cases of syphilis, and others occurring in the female wards, which require a private examination."

I beg leave to answer—

First. That St. George's is not a hospital into which syphilitic cases, as such, are admitted. If he wishes to see them, why does he not go to the Lock?

English hospitals are, thank God, unconnected with the Government. They were founded and endowed, not as medical schools, but as refuges for the sick, and, therefore, the sick in them must be respected.

Next, he adduces the privileges of the American students in Paris; but nine-tenths of these come there with a diploma of some sort or other. I state this from my own experience, as a member of the Parisian Medical Society, in the Rue Racine, to which almost every decent American student belongs.

But even if your correspondent had the same standing as they, and the *prestige* of a foreigner to boot, will he dare to compare the women of the middle classes, whom he will find in St. George's, with those of the Parisian hospitals? or does he actually intend to put syphilitic cases on the same footing with the diseases of modest women? And, after all, does he fancy that, in three Continental hospitals out of four, he would be allowed to inspect these cases thoroughly anywhere but at a private "*cours*"? Unless he did—what he ought to be obliged by law to do at St. George's—to become a dresser and a clerk?

By taking that honourable trouble, he would save each woman the insult of the presence of some twenty boys, cutting their jokes, or, at least, making audible remarks, on the disease, which she endeavours to hide, with at least a remnant of womanly modesty. He will save her the torture of some twenty successive unskilful applications of the speculum, repeated until the whole class shall consider themselves perfectly *au fait* on the state of her os uteri. He will not outrage that respect for common decency and delicacy which young students too often throw aside, till they find it necessary in after years, for their own manhood's sake, to recover it. And when he has, by thus attending women with his physician, gained a little experience, let him take, as he easily may, midwifery cases, &c., from some Dispensary; let him get a character for kindness and skill among the poor, and I will engage that he shall see enough to teach him all he needs, without subjecting any woman to unnecessary shame, merely for his own private interest.

I remain, Sir, your obedient Servant,

AN OLD STUDENT OF ST. GEORGE'S.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—A numerously attended meeting of the Fellows of this College took place on the 1st inst., in the Theatre of the Institution, to elect two Members of Council to fill the vacancies occasioned by the resignation of Mr. Richard Welbank, and the lamented death of Mr. Aston Key. The President commenced the proceedings by stating the object of the meeting, and calling on the Secretary to read the names of Fellows from the Chronological List, when that of Mr. George Pilcher, of Great George-street, Westminster, having been announced, Mr. Thomas Bell, seconded by Messrs. Kiernan and Selby, rose and proposed him as a fit and proper Member for a seat in the Council. The next name proposed was that of Mr. John Bishop, of Bernard-street. Mr. Guthrie, the late President of the College, stated, that he had known Mr. Bishop upwards of twenty years; that he had great pleasure in proposing him as a gentleman well qualified for a seat in Council; and that, if elected, he was sure the gentlemen supporting him would not regret it. Mr. Guthrie was followed by Messrs. Wormold and Hancock, who expressed the pleasure they had in seconding the nomination of Mr. Bishop. The names having been suspended, the Fellows proceeded to ballot. The numbers were, for Mr. Pilcher, Ayes 67; Noes 41. For Mr. Bishop, Ayes 89; Noes 23. The President then declared Messrs. Pilcher and Bishop duly

elected members of the Council of the Royal College of Surgeons.

OBITUARY.—At Clapham, aged 65, Edwin Tipple, Esq., Surgeon, late of Mitcham, Surrey.—On the 12th of June last, at Sydney, New South Wales, after a few days' illness, John Loftus Hartwell, Esq., Staff-Surgeon, 2nd class.

KING'S COLLEGE HOSPITAL.—Last week a meeting was held in the Board-room of the above charity in Portugal-street, Lincoln's-inn-fields. Some interesting details were given relative to the pestilence which has so lately passed over the country. It appears, that from the commencement of the disorder, the hospital was open to all patients, and as the epidemic increased, the medical staff, both for daily and nightly attendance, was augmented, the nurses of the establishment doubled, and every means taken, not alone to relieve the afflicted, but to investigate the disease itself. Out of 123 cases of decided cholera, during the height of the disease, 83 yielded to medical treatment (the patients being discharged cured,) while the fatal cases were confined to half that number; the majority of the deaths were among the earlier patients, the course of treatment eventually adopted having had the result of rendering the fatal cases extremely rare. The diarrhœa patients numbered many hundreds, and the treatment was invariably attended with the greatest success. The expenditure of the hospital during the quarter was 795*l.* 6s. 6d., while that of the corresponding period last year did not exceed 550*l.* The large addition to the number of nurses, &c., caused this increase of expenditure, and it was decided that an appeal should be issued to liquidate the debt incurred under such urgent and peculiar circumstances.

CHAIR OF SURGERY, TRINITY COLLEGE, DUBLIN.—Dr. R. Smith, author of the work on injuries of the joints and of the Monograph on Neuroma, was elected by the Board of Trinity College, Dublin, Professor of Surgery in the School of Physic, on the 19th ult.

SCHOOL OF MEDICINE OF THE APOTHECARIES' HALL OF IRELAND.—Dr. Corbett has been elected by the General Council of the Apothecaries' Company Professor of Anatomy, in place of Dr. Alcock, appointed to Queen's College, Cork.

DR. MACKENZIE has been appointed one of the physicians to the Kelso Dispensary. The vote, in accordance with which he was appointed, is rather singular. "The meeting" (of the Governors) "return their thanks to Dr. Mackenzie for the offer of his services, and are happy to avail themselves of his professional abilities in carrying out the benefits of the charity, and appoint him one of the physicians of the Dispensary. (Signed,) WILLIAM SMITH, President."

THE CHOLERA.—From the Registrar-General's Return this week, we find that the cholera may be considered as almost extinct in London, only twenty-five deaths being recorded from this cause. The general mortality is also considerably below the average, there having been only 902 deaths from all causes, the average of five autumns being 1162. From the provinces we also learn that the cholera is rapidly declining, and, should this favourable state of things continue it will soon have passed away.

REMUNERATION BY INSURANCE OFFICES TO MEDICAL REFEREES.—This much-vexed question seems fast settling into a recognition of the fair claims of Medical men. "The Royal Insurance Company" (of Liverpool and London) announce, in our advertising columns this day, their readiness to allow a fee to any Medical man who may be referred to in the establishment of a policy. They will, no doubt, find this to be a move in the right direction If "honesty" be "the best policy," liberality is no less so.

ROYAL POLYTECHNIC INSTITUTION.—We trust our readers occasionally frequent the Polytechnic. We know no more agreeable or useful mode of spending an otherwise unoccupied hour; and we would assure those who have not visited the Institution,—if, indeed, any such there be, that, whatever may be their tastes, and whatever branch of science they may cultivate, they cannot fail to find much both to amuse and instruct. To young people especially must Mr. Ashley's lectures on chemistry be very interesting. They explain many facts of daily occurrence, which are passed over almost unnoticed on account of their familiarity, but the knowledge of which is, nevertheless, fraught with wondrous import and lead the inquiring mind from Nature up to Nature's God. Dr. Bachnoffner's lectures on electricity are well worthy attention; and the gigantic power of the machinery with which he illustrates his subject cannot fail to excite the most intense interest.

THE KELSO BOARD OF GUARDIANS.—A writer in the *Kelso Mail*, alluding to a paragraph contained in a recent Number in this Journal, headed, "Spirited conduct of Parochial Medical Officers at Kelso," makes a great deal of a trifling error it contained, and which he parades before the little world in which he lives, as an illustration of the confidence to be placed in our statement. We plead guilty to the error we are charged with—the mere interpolation of a word. The parsimony of the Kelso Board is still most glaringly displayed. A fearful pestilence, devastating the land, broke out in Kelso, and the Board of Guardians assuming the functions of a Board of Health, without the least claim or qualification for the office, determined to carry out a similar principle in its subordinate appointments. It would appear that the system of house to house visitation, the discontinuing of which was lately reprobated by us, was not effected by means of medical men, but by working men, who, according to the *Kelso Mail*, though very respectable persons in their stations, did not possess the necessary knowledge of medicine or medical subjects. It was partly on the *dicta* of some of these, opposed to the opinions of the medical staff, that the house to house visitation system was done away with. Can there be a doubt, that these Kelso Guardians were more anxious to enjoy authority and patronage, than to serve the public? We do not for a moment believe that in any other town, city, or village, were working men, totally unacquainted with medicine or with medical subjects, appointed to so onerous and so responsible an office. Parsimony generally marks the conduct of Parochial Boards with regard to medical matters. It remained for the Kelso Board to exhibit it in a very glaring manner by the proceedings to which we have alluded, and subsequently by the indecent haste with which they removed their visiters when the disease began to decline. We fear that the detection of the very pardonable error we committed in our account of the proceedings of these guardians has not placed them in a better light; on the contrary, it has shown that their conduct has been throughout consistent, but consistent in wrong-doing. They commence by insulting their medical officers, by giving them working men as assistants to trace the disease in its earliest stage; and they conclude by still further insulting them by preferring the crude opinions of working men as to the necessity for their continuing in office, to the enlarged, and comprehensive, and philanthropic views of the Profession. It is to be regretted that cobblers will not stick to their lasts.

MEDICAL OFFICERS AND BOARDS OF GUARDIANS.—On the 22nd ultimo we reported in the *Medical Times*, a case partially tried in the Cheltenham County Court on the previous Tuesday, wherein Mr. J. Hyett, a late medical officer to the Cheltenham Union, brought an action against the Guardians to recover the balance of an account due to him for extra medical attendance, amounting to 13*l.* 1s. 6d. The action was defended, and the jurisdiction of the judge, Mr. J. Francillon, objected to, on the ground that, as a Justice of the Peace for the county, he is, *ex officio*, a Poor-law Guardian, and therefore one of the defendants in the cause. His Honour over-ruled the objection, and would have heard the case at the time, except that an adjournment for a month was agreed to by the professional men engaged on either side. The case came on again on Tuesday last, when it was announced that the attorney for the defendants, with the consent of his clients, had moved a judge in chambers, Mr. Justice Talfourd, for a writ of *certiorari* to remove the case into a superior court. Affidavits were made in support of the application setting forth the grounds upon which it was made, namely, the peculiar position of the district judge. Justice Talfourd ordered a writ to issue within a fortnight, provided the defendants paid the plaintiff all costs incurred up to that time. A copy of this order had been served upon Mr. Francillon; but, in remarking upon it on Tuesday, His Honour said, such an order was no prohibition to him, for no writ was actually issued, nor was the order addressed to him. It deserved, however, to be treated with respect as coming from a judge of a superior court. Mr. Pruen, the plaintiff's attorney, said he must ask for another adjournment of the case for a month, in order to see whether the defendants would pay the costs with a view of taking the cause into a superior court. His Honour granted the adjournment. Should the case be removed by *certiorari*, it will be tried at the Gloucestershire Assizes in March next and, should the plaintiff win the day, the costs to the parish in disputing a just claim of 13*l.*, will be little short of 100*l.* It is expected that the district auditor will refuse to pass such an account; at least it will cause much dissatisfaction amongst the ratepayers.

YELLOW FEVER.—A Commission of Army Medical Men has been sitting for some time collecting evidence, and examining witnesses, respecting the nature, progress, and treatment of this formidable disease. Very absurdly, the inquiry appears to be limited to Medical men connected with the Army; whereas, those employed in Her Majesty's ships of war, more especially those who have served on the African coast, could furnish important information. We trust the inquiry will be further extended, and medical men engaged in civil practice on the coast of Africa and in the West Indies, be also applied to for the results of their experience. Then, and then only, can a satisfactory conclusion be otherwise.

THE EDUCATION OF IDIOTS.—An excellent lecture upon this very important and interesting subject was lately delivered at Brighton, by Mr. Levison, Surgeon-Dentist. Mr. Levison stated that idiots were brought into the world with defective mental capacities—often with imperfect external senses, and with malformed bodies. To aggravate their misery, they had heretofore been abandoned, as if altogether incapable of being improved, either physically, morally, or intellectually. But this fatal doom, he said, resulted from an ignorance of organic laws, and because it was not known that improvement could with certainty be calculated upon. He should, therefore, have the satisfaction of submitting to them important facts, to prove that the defective powers of the unfortunate beings for whom he pleaded, could be improved; that in scarcely any case would there be an entire failure, whilst in most instances there would result a great amelioration. This problem, he said, had been triumphantly solved in France: that lately an institution for the education of the idiot had been established in this country, and so far it was found that the system answered extremely well. To confirm these statements, Mr. Levison submitted a number of anatomical and physiological details, showing that data existed to prove that the brains of partial idiots indicated relative but not absolute deficiency; that in the lowest organizations, the poor beings could distinguish relatives from strangers, particular kinds of food, and also different places, which proved that they possessed certain perceptive faculties, such as individuality, form, size, &c., which, when trained according to the system he should explain, would enable them to acquire a knowledge of written signs and oral sounds, and thus learn to draw, to write, and to read. Mr. Levison practically illustrated his views by the history of several cases of training under the system he advocated; he showed the happiest results arising from it, and received a vote of thanks from a highly attentive and respectable audience. We sincerely trust that the matter brought thus prominently forward, and backed by an Institution for the education of idiots, will receive the cordial and effective support of a generous and philanthropic public

COST OF EPIDEMICS.—The cholera has, it is said, cost the ratepayers of the metropolis for medical attendance, medicine, funerals, &c., 200,000*l.*, besides an annual cost, for some years to come, at the least, of from 15,000*l.* to 20,000*l.*, for the maintenance of the widows and orphans of those now no more. Now, to what immense advantage (says the *London Observer*) could a moiety of this large amount have been applied, if the authorities had taken warning by the former epidemic in 1832, and the ravages which typhus, small-pox, and other zymotic diseases, are constantly producing, and had directed their attention to the sources from whence the expenses had arisen. Had but a tithe of this sum been used for sanitary purposes,—had the state of the labouring, hard-working, but too frequently starving artisan been looked into,—had his miserable hovel been changed to a comfortable dwelling, after the plan of the model lodging-houses,—had he had a sufficiency of pure water for drinking, and to wash away the dirt consequent upon his avocations,—we should say we should not have had this enormous amount to defray, nor should we have had, as it were, to pass through the "valley of the shadow of death." In improving and aiding the poor, we are benefitting ourselves, for we increase largely our own chances of life, and, at the same time, save our money.

ALLEGED BURYING ALIVE.—In the midst of exaggeration and invention, says the *Quarterly Review*, in its last number, there was one undoubted circumstance which formerly excited the worst apprehensions—the fact that bodies were often found turned in their coffins, and the grave-clothes disarranged. But what was ascribed, with seeming reason, to the throes of vitality, is now known to be due to the agency of corruption. A gas is developed in the decayed body which mimics, by its mechanical force, many of the movements of life. So powerful is this gas in corpses that have lain long in the water, that M. Devergie,

the physician to the Morgue at Paris, and the autho of a text-book on legal medicine, says, that unles secured to the table they are often heaved up an thrown to the ground. Frequently strangers, seein the motions of the limbs, run to the keeper of th Morgue, and announce, with horror, that the perso is alive. All bodies, sooner or later, generate gas i the grave, and it constantly twists about the corp blows out the skin till it rends with the distensi and sometimes bursts the coffin itself. When th gas explodes with a noise, imagination has convert it into an outcry or groan; the grave has been r opened; the position of the body has confirmed th suspicion, and the laceration been taken for eviden that the wretch had gnawed his flesh in the fren of despair. So many are the circumstances whic will occasionally concur to support a conclusion tha is more unsubstantial than the fabric of a dream.

METEOROLOGY OF THE WEEK.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Oct. 27, 1849.

Causes of Death.	Total.	Average of Five Autumns
All Causes	902	1162
Specified Causes	902	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	229	307
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	76	49
Tubercular Diseases	139	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	108	125
Diseases of the Heart and Blood vessels	41	40
Diseases of the Lungs, and of the other Organs of Respiration	132	211
Diseases of the Stomach, Liver, and other Organs of Digestion	58	
Diseases of the Kidneys, &c.	11	11
Childbirth, Diseases of the Uterus, &c.	16	1[illegible]
Rheumatism, Diseases of the Bones, Joints, &c.	6	
Diseases of the Skin, Cellular Tissue, &c.	2	1
Malformations	1	4
Premature Birth and Debility	19	23
Atrophy	25	18
Age		57
Sudden		12
Violence, Privation, Cold, and Intemperance		36
Causes not Specified		4

The following is the number of Deaths occurring from some of the more important special causes:—

Apoplexy ..		Heart	41	Phthisis	9
Bronchitis ...		Hooping-cough	16	Pneumonia ...	6
Cholera.........		Hydrocephalus	25	Scarlatina	33
Childbirth		Influenza		Small-pox	7
Convulsions...		Liver		Stomach	
Diarrhœa		Lungs		Teething	
Dropsy		Measles		Typhus	52
Erysipelas ...		Paralysis		Uterus	

BIRTHS AND DEATHS.

	Births.	Deaths.	Births over Deaths.
Males	686	442	244
Females	642	460	182
Total......	1328	902	426

TO CORRESPONDENTS.

The importance and the great length of the Report of the Cholera Committee of the College of Physicians, oblige us to omit several valuable communications: Professor Owen's Hunterian Lecture; Professor Quain's Clinical Lecture; and Dr. Letheby's Chemical Lecture, will appear next week. We have also in print a continuation of Mr. M'Dougall's Papers, and communications from Dr. Tripe and others. Our Edition of Dieffenbach, by Dr. Bushnan and Mr. Ure, must also stand over, as well as the Report of the Medical Society of London, Mr. Hobson's Case of Popliteal Aneurism, and a great extent of correspondence.

"Philo Scientiæ" asks the method of preparing Bromide of Cyanogen. Two parts of bicyanide of mercury and one of bromine are mixed together in a retort, which produces considerable rise of temperature. As soon as this action ceases, a gentle heat is to be applied, when the bromide of cyanogen passes over and fills the neck of the retort in the form of white cubic crystals, very volatile, gaseous at 80°, and soluble in water and alcohol.

"Post mortem" wishes to know, "whether cadaveric rigidity is a sure sign of death" It is generally considered so. Louis affirms that this is a most certain indication. He examined the bodies of more than 500 persons just after they expired, and always found, shortly after the extinction of life, that the articulations began to stiffen, even before the temperature of the body was sensibly diminished.

A Student of St. Thomas's" inquires "why this Hospital is called a Royal Hospital?" Because founded by King Edward VI. Previously it was an Almshouse, established by a Prior of Bermondsey in 1213.

"A Young Surgeon."—The appointment of Assistant-Surgeons in the army rests with Sir James M'Grigor, to whom we recommend our Correspondent to apply.

"Vaccinia."—The vaccine vesicle is confined to the part where matter is inserted.

"G. B. L."—Mucus in the urine may be distinguished from pus by the addition of acetic acid, mucus, also does not contain albumen in sufficient quantity to be coagulated by heat or nitric acid.

Anti-quack" inquires whether the College of Surgeons has the power of expelling any member who is the proprietor of a nostrum.—No.

A Member of the College."—Mr. Fellow's opinion is a mistake. Mr. Chitty was the gentleman intended to be consulted, and his views on the subject are entirely different. Our Correspondent's fears are, therefore, groundless.

F. S."—A kilogramme is rather more than 2 lbs., 3 oz., 4 drachms, avoirdupois.

A Country Surgeon" directs our attention to the circumstance of some medical practitioners in London placing their diplomas in their windows for public inspection. Such a practice is degrading to those who adopt it; and only very ignorant persons are attracted by it.

A Subscriber."—The sum named for the setting of the fracture is "reasonable," and may be recovered at law.

A Licentiate of the Apothecaries' Company."—A person having only a foreign diploma cannot recover for medicine and attendance in England.

Lector."—The Registrar of the University is the proper person to whom a letter should be addressed.

Galen" directs our attention to the circumstance of many diseases occurring in consequence of newly-built houses being too quickly inhabited. He says, that in various parts of the outskirts of London, a large number of new dwellings are constantly being erected, and scarcely are they completed before they are occupied. Five cases of cholera which proved fatal in persons who had recently taken new-built houses came under his superintendence, which he considered were produced by the exhalations from the damp walls and floors and the fresh paint. We believe that newly-built houses, when too quickly occupied, exert a very baneful influence on the health of the occupants. From the fresh materials which compose the dwellings, deleterious exhalations arise, contaminating the air. Houses ought not to be inhabited for a certain period after their completion; and our medical brethren should caution those within their influence of the dangers to which families are exposed by living in houses recently erected.

"A Constant Reader" directs our attention to the fact of the Registrar of Births in many districts being either a parish clerk, a stationer, a shoemaker, or some other tradesman. This circumstance, our Correspondent thinks, makes the office of Registrar so low, as to be unworthy the attention of a respectable medical practitioner. Nothing is gained by its being held by him, so far as the accuracy of the returns are involved; while it gives the surgeon, who holds the office an advantage over his professional brethren in obtaining patients. Our correspondent says, in his district, the Registrar, a medical man, is also vaccinator, "and he has not failed to follow up the registration of the infant by pushing its future vaccination—looking up the cases very attentively at their own houses. I could cite many cases where a medical man, holding the office of registrar, has obtained many undue advantages. The office may be equally well performed by the parish clerk or undertaker." We differ from our correspondent as to the propriety of cobblers, undertakers, or grocers being Registrars of Births and Deaths. A medical man is certainly the proper person, and we think that few would make use of the office to promote their own private interests, at the expense of their brother Practitioners.

"Medicus Juvenis."—Pregnancy frequently occurs during lactation. It is quite possible for conception to take place under the circumstances stated.

"T. C. D."—As both, within the jurisdiction of his University.

"Dr. King."—When Dr. King has perfected his Report, perhaps he will kindly communicate with us.

We are obliged to Mr. Moore for the return of the Cholera Table.

"Mr. John Beedell, jun., of Tiverton," is informed, that Mr. Wardrop's Work on the Heart will most certainly terminate with the present Volume of the "Medical Times."

Dr. Young, of Gravesend," has returned to us our Cholera Table, with a report of seventeen cases treated by him. He seems to have found much benefit from large doses of Calomel and Carbonate of Iron, which, he informs us, rapidly arrested the serous discharge from the bowels. We take this opportunity of requesting practitioners kindly to return our Table, with the results of cases, at their earliest convenience.

Dr. Reed Clanny, of Sunderland."—The request has been cheerfully complied with. We are obliged by Dr. Clanny's commendations and good wishes.

"Dr. Waller's" excellent communication on the employment of Ether and Chloroform in cases of Midwifery will appear next week.

Dr. Dingam on Cholera."—In our last week's publication this gentleman's name was printed "Dingham." It is Dingam.

"Mr. Bulley's" cases of bilious cholera treated by hot water applications to the abdomen, have been received.

"Dr. Mair, Staff-Surgeon" is thanked for his communication from Kingston, Canada West.

Dr. Crisp, we think, will, upon consideration, agree with us, that the matter to which he kindly alludes had better be allowed to pass unnoticed; especially as effectual means have been taken to prevent a recurrence.

"Dr. Kidd's" paper on Continental Medicine is received, and will receive early insertion.

"Mr. Hooper, Operative Chemist, of Pall-mall East," has written to us upon the subject of his Vulcanised Indian-rubber Cushions. Though highly approving of his invention, we cannot, this week, find room for his communication.

"Mr. Collins" is thanked for a bottle of the "Patent Infecting Powder, for the prevention of Cholera, Typhus, and other Fevers, by destroying malaria and offensive smells." We shall test its powers when occasion offers.

"Dr. Nankivell, of Torquay," is thanked, but respectfully declined. Upon another occasion, and under other circumstances, we shall be happy to hear from him.

We have several reviews waiting an opportunity to appear in our pages. We hope in our next number to find space for Cruveilhier's "Traité d'Anatomie Générale;" and in early numbers for Dr. James Henry Bennett's "Practical Treatise on Inflammation of the Uterus and its Appendages, and on Ulceration and Induration of the Neck of the Uterus;" Mr. Rynd's "Pathological and Practical Observations on Strictures and some of the Diseases of the Urinary Organs;" Mr. Stanley on "Diseases of the Bones;" Dr. Daniell, on the "Medical Topography and Diseases of Guinea;" Mr. Grantham's "Facts in Medicine and Surgery;" Noad's "Electricity;" and many others. The "Cyclopædia of Anatomy and Physiology," edited by Dr. R. B. Todd, especially demands our early attention.

ORIGINAL LECTURES.

HUNTERIAN LECTURES.

ON THE

GENERATION AND DEVELOPMENT OF THE INVERTEBRATED ANIMALS.

By RICHARD OWEN, F.R.S.,
Hunterian Professor and Curator of Museum of Royal College of Surgeons, Corresponding Member of the Institute of France, &c.

[Reported expressly for the "Medical Times," and revised by the Lecturer.]

LECTURE XIII.

NATURE AND AFFINITIES OF TRILOBITES ILLUSTRATED BY THE EMBRYOGENY OF CRUSTACEA.—Development of ovum and germ.—Metamorphosis and larval "Nauplius" of Cyclops: progressive confluence of the two eyes — Tailless trilobitiform larva of Limulus.—Metamorphosis of Pagurus and Crangon. larval *Zoea* and *Megalops* of the Brachyura.—More direct and regular development of the Craw-fish.—Transitory manifestations of characters and structures of inferior Crustacea in the course of the development of the higher species —Predominance of larval forms in ancient geological periods

MR. PRESIDENT AND GENTLEMEN,—The wider our survey of living nature extends—the greater the number of facts in the history of animals with which we become acquainted—the more do the points of correspondence between the different species increase, and the clearer becomes our conception of the unity of the general plan which pervades their organisation. This is especially the case with regard to the phenomena which we recognise in tracing the development of particular animals. But, before entering on the proper subject of this day's discourse, viz., the phases of the development of the individual Crustacean, I will premise a few remarks on the phases which this class itself has passed through from the period when we first recognise it amongst the animals that have heretofore peopled our planet.

To render my remarks on the Paleontology of the Crustacea intelligible, I may remind some of my hearers, that, at the present day, the class is naturally divisible into two great groups; but not, as Leach and Macleay believed, according to the sessile or pedunculate character of the eyes, for you find eyestalks in Entomostracans—to use the language of Leach, "podophthalmatous" species may be found amongst the lowest Phyllopoda, *e. g.*, in the genus *Branchipus*,—as well as in the highest members of the class. We must seek, therefore, some more constant and important character for our primary division of the Crustacea, and this character is found in the constancy of the number of the segments composing the body in certain members, and the variability of the number of segments in the rest of the class. Three primary divisions of the body may generally be recognised, viz., the head, the thorax, and the abdomen; the latter being, also, sometimes called the post-abdomen, or tail; but it is traversed by the intestine. In the actual majority, including the typical members of the class, the thorax includes seven segments, the abdomen seven segments, and seven are likewise indicated by the appendages in the head, twenty one being the typical number of the segments in the division of the Crustacea, called "Malacostraca;" at all events, the number seven is constant with regard to the thoracic segments and the abdominal segments in this sub-class. In the other, and lower, sub class, the number of segments varies, is often more, and sometimes less, than seven, and this sub class is called "Entomostraca."

The Malacostraca are again divided according to the relative length of the thorax and abdomen, or according as they have "long" or "short" tails, as the latter part is commonly called; in accordance with which, the technical names of these subdivisions, or orders, have been devised. The lobster is the type of the *Macroura*, or long-tailed order, and the Crab of the *Brachyura*, or short tailed Crustaceans. But Nature never moves *per saltum*, and there is a little groupe which has an intermediate proportion of the abdomen, and it has been called "Anomoura."

All the three orders are represented in the tertiary formations and in their Pliocene, Miocene, and Eocene divisions; but no species of crab, or brachyurous Crustacean, has hitherto been met with in strata more ancient than the Eocene. In the chalk formation, the highest form of Crustacean would be classed with the "Anomoura" of the French naturalists; but the Macroura are the prevalent forms. Lobsters, crawfish, shrimps, and other Macroura, but all of species now extinct, are met with fossilised in the secondary strata, from the chalk to the coal formation; but below the chalk, there are no higher forms of Crustacean than the Macroura. When we come to the coal-measures, the Malacostraca disappear; but we then find the gigantic Entomostracan called the King Crab, or *Limulus;* thence down to the lowest strata in which any trace of animal life has been found, the Crustaceou class is exclusively represented by Entomostracous species, and more particularly by a peculiar form of Entomostraca, which became extinct before the coal-measures were deposited. Almost endless, however, are the varieties under which this form was manifested in the Palæozoic periods: the term "trilobite" is given to the fundamental type or form, on account of the segments of the body being divided into three lobes

Our countryman Lhwyd, or Lloyd, first discovered this fossil in 1699, and he gave it the name of *Trinucleus*. At that time zoological science was not sufficiently advanced to afford a definite binomial sign for the extinct animal; and Lloyd's name rather indicated the petrifaction as such, than a species of the animal kingdom. This idea first arose about the time of Linnæus, by whom the fossils in question were placed in the class of insects, with the name of *Entomolithus paradoxus*. Knorr next studied it, and gave it the name of "Trilobite," believing it to be allied to the molluscous Chitons, which opinion prevailed to the time of the Entomologist Latreille, and died with him. The better preserved fossils, in fact, gave evidence of distinct organs of vision, large eyes, divided into numerous segments, and thus proving that the Mollusca could not be the primary division of animals to which the Trilobites belonged; and since that time, all naturalists have agreed in referring these fossils to class *Crustacea*.

With regard to their nearer affinities, all who had studied the Trilobites up to 1843, were of opinion that they were allied to the higher, or Malacostracous, division of the Crustacea; and Mr. Macleay, in his valuable appendix to "Murchison on the Silurian Strata," places the Trilobites in a distinct order between the Isopoda and Aspidophora. He based his views on the trilobed character of the segments in *Serolis* and *Bopyrus*, and showed that the eyes were large, sessile, and compound in Cymothoa, as in Trilobites. The *Cymothoa* and other Isopods, or wood-lice, roll themselves up into balls, as we find many of the Trilobites to have done before they perished But we find these characteristics also in the *Limulus* the segments of the hinder division of its body are divided into three elevations, or lobes; the large, sessile, compound eyes of *Limulus* are more like those of the Trilobite than the eyes of Isopoda are; and the larval Limuli roll themselves into a ball. Moreover, the excess in the number of the segments of the thorax or abdomen, over and above the number seven, which governs them in the Malacostraca, proves the particulars of resemblance to the sessile-eyed members of that sub-class, which Mr. Macleay indicates, to be no characters of immediate affinity to the *Cymothoidæ* or to the *Epicaridæ*, although some of these, like the *Sphæroma*, may present a large, convex, semicircular anal segment, such as we see in the Trilobitic genus *Bumastes* of the Silurian strata.

In my lecture on the Crustacea, delivered in this theatre April 27, 1843, and published in the following month, I introduced the Trilobites with the following remark :—"The distinction between the Entomostraca and Malacostraca, in the numerical character of the segments of the body, is of the first importance in determining the affinities of those ancient extinct Crustacea, called 'Trilobites.'" —Lectures on Invertebrata, p. 165. And I pointed out how *Bopyrus* and *Cymothoa* differed by their normal number of thoracic and abdominal segments, viz., 7–7. M. Burmeister, in [illegible] (1843), with equally [illegible] of this [illegible] [illegible] it, in determining the position of these animals in the System Naturæ, and [illegible] invalidated the marks of resemblance which [illegible] been noticed between certain Isopods and Trilobites. But, he errs, I believe, in thinking [illegible] still more widely removed from the Trilobites than the Isopods are, not apparently knowing the Limulus in its larval state. Professor Emmerich, in a memoir in Bronn's Neuer Jahrbuch, 1845, regards the Trilobites as a peculiar order, connecting the *Malacostraca* with the *Entomostraca*, but more nearly related to the latter. He thinks them allied to the Malacostraca by their crust-like shell, and by their not possessing simple eyes together with compound ones; but this combination is rare even in the *Entomostraca*. He deems the *Limulus* and the *Phyllopoda* to be the two orders of Entomostraca to which the Trilobites are united by the nearest characters of affinity. They correspond with both as regards the form and size of the clypeoid head or cephalo-thorax. The soft texture of the under side of the body of the Trilobites, and the circumstance that no one has yet succeeded in detecting unequivocal vestiges of legs, are in favour of the supposition that they must have corresponded, in the perishable structure of their feet, with the *Apus* and *Branchipus*. But, to what end, you may ask, tends all this discussion concerning the affinities of animals, that have long since ceased to exist? How are we concerned with it, in considerations relative to the generation and development of the actual Crustacea? To this I have to answer, that it is only by a knowledge of the transitional larval forms of these, that we come rightly to comprehend the nature and affinities of the ancient *trilobites*:, and that our knowledge of the most interesting relations of actual larvæ requires a previous knowledge of the forms of their class that have heretofore existed in this planet. In no mature stage of any existing Crustacean do we find the trilobites so closely resembled, as they are by the larval stages of the *Limulus*, and of some of the smaller *Entomostraca*. The metamorphoses of these are such that different stages are figured as distinct species in the well-known work "On Entomostraca," by O. F. Muller. In the larval cylops, which is his genus *Nauplius*, the eyes are distinct; but, in the course of the first and second moult they approximate, and finally unite together. The body of the larval *Branchipus* consists at first of two oval divisions, like the spiders; that which represents the thorax and abdomen united has no legs; but two pairs of natatory setigerous legs, and two antennæ, are developed from the head, which has a single median eye. The form of the head is also different. After the first moult the head has three eyes, a pair being added to the first median one; but all are sessile. The abdomen elongates, and divides into rings, and is now provided with rudimentary tubular feet. At the secondary moult, the first pair of foliaceous feet appear, succeeded by seven pairs of rudimentary ones. In succeeding moults the lateral eyes become pedunculated, and the median eye disappears; the abdomen grows longer, and its limbs are perfected. The *Apus* quits the egg with fewer segments than it afterwards acquires. The larval *Sao* has but three thoracic segments, but the number of these increases with each successive moult, until the adult form is acquired: the new segments being developed between the thorax and abdomen. Similar metamorphoses have been evinced by fossil specimens of the tribolitic genus *Ogygia*, in which the additional segments were developed at the hinder part of the abdomen.

One cannot witness the earlier stages of *Branchipus* and *Apus* without being struck by their resemblance to certain forms of Trilobites. And so likewise with the larva of the Limulus. The argument against the affinity of this genus to the Trilobite which had most weight with Burmeister, was the peculiar bayonet-shaped weapon proceeding from the post-abdominal division of the body in the fully developed King-crab. Now, when it quits the ovum, this weapon is

not developed; the cephalo-thorax is relatively smaller; the abdomen longer, and more trilobed, and altogether the larva is much more like the Trilobite than the later stages. The cephalo-thoracic shield is enormous in the larval *Sao*, but becomes reduced to comparatively small dimensions in the adult animal. Some of the forms of the smaller Trilobites, which figure as distinct genera, *e.g.*, *Battus* and *Agnostus*, may also be larval forms of other genera; for, like the existing Entomostraca, the Trilobites underwent their metamorphoses, which, as in the case of the *Ogygia*, were, also, of a similar nature. Therefore, by these facts in the development of the lower Crustacea, few indeed, I admit, when compared with the great number of known Entomostraca that now exist, a clearer light is thrown on the real nature of those ancient Trilobites than could have been expected in regard to extinct creatures, the affinities of which were so long and so lately considered problematical.

The ova, after extrusion from the oviducts, are retained and protected in the *Cymothoa* and other sessile-eyed Malacostraca by means of the flabelliform appendages of the extremities, which appendages are unusually expanded, and overlap each other, so as to form a marsupial cavity or temporary receptacle, in which the incubation of the ova is completed. In the Podophthalma, the lamelliform ciliated appendages of the abdominal segments include similar marsupial or incubatory recesses for the ova. The female lobster and other Macroura are distinguished from the male by the greater development of these appendages, and in the Brachyura the shorter abdomen or tail is so much more expanded in the females as to cover nearly the whole sternum, and render the sex distinguishable at a glance.

With regard to the higher groups of Crustacea, up to a late period naturalists had believed that they differed from insects, as well as from *Entomostraca*, in undergoing no metamorphosis, but they offer differences in this respect in different species. The phenomena of development common to all are the following:—The primary germ-vesicle, after impregnation of the ovum, propagates its progeny not at the expense of the whole germ yelk, but only of a small portion of it; so that the process of yolk fission is a partial, not a total one: all Crustacea show the same direction of development,—*i.e.*, they obey the law of the Articulate type by the commencement of the embryo at its ventral surface,—it is literally built up from below, and consequently the umbilicus, or the last cicatrix closing in the yolk-sac, is on the back; the body is completed by the finishing of the segments or rings at the dorsal surface of the body. In regard to the Malacostraca, there are many modifications of the secondary or subsequent phenomena of development. As long ago as 1788, a Dutch naturalist, Slabber, described and figured a minute swimming Crustacean of the genus called *Zoea* by modern naturalists; it was provided with a pair of large and distinct eyes; its carapace was armed with a long frontal and a dorsal spine; and its abdomen was terminated by a forked tail. He preserved this little animal alive in sea water, which was daily renewed, and on the fourth day he found that the animal had changed its form; the feet, eyes, and antennæ were more developed, the frontal spine had become comparatively small, the dorsal one had disappeared, and the tail had changed from the bifurcate to the spatulate shape, and was fringed by a row of short spines. Many years elapsed ere this observation was repeated, and it seems to have been forgotten, when Dr. Leach, the most accomplished Crustaceologist of his day, founded the principal character of the class Crustacea on the absence of metamorphosis.

During the spring of 1822, Mr. V. Thompson, to whom we are indebted for the discovery of the metamorphoses of the Cirripedes, captured an abundance of the singular Zoea in the harbour of Cove; the largest of them was daily supplied with fresh sea-water from May 14th until the 15th of June, when it died in the act of changing its skin. The disengaged members, invested with the new integuments, were changed both in number and form, and corresponded with those of the decapod Crustacea, the anterior pair being furnished with large pincers. Here, therefore, was a strong indication that, under the form of a Zoea, was masked that of some one or other of the higher Crustacea; and, probably, one of the common species of the Irish coast. To the development of these, therefore, Dr. Thompson next turned his attention, and he succeeded in hatching the ova of the common crab during the month of June, and found that the young were excluded under the form of the *Zoea Taurus*, with the addition of lateral spines to the thorax; whereupon he concluded that the decapod Crustacea indisputably underwent a metamorphosis.

These observations were, however, called in question, after the appearance of the elaborate monograph by Rathke, on the development of a fresh water species.

In the year 1829, Dr. Rathke published his "Researches on the River Craw fish (*Astacus Fluviatilis*). In this species the ovum first appears in the shape of a minute transparent vesicle, which afterwards becomes surrounded by a second, forming the membrana vitelli; the nature of the processes effecting this stage appears not to have been observed. The yolk increases in quantity, and is rendered opaque by the presence of numerous granules, or nucleated cells, which are at first angular, and change from the lenticular to the spherical figure; then the internal minute transparent germinal vesicle quits the centre, and comes into contact with one part of the parietes of the ovum. The colour of the yolk successively changes to yellow, orange, and brown; the spermatozoa, enveloped in their spermatophore, when they are received into the oviduct, escape therefrom, and ascend the duct to the ovarium, and after coming into contact with the ovum, the clear vesicle disappears, and the production of the embryo commences. Rathké failed to ascertain what became of the vesicle. The formation of the ovum in the ovary continues half a year. In the month of November the vesicle was visible; in the ensuing March it had disappeared.

The ovum escapes into the oviduct by bursting the inner lining of the ovary. It is surrounded by a layer of albuminous matter, and is enclosed within a coriaceous chorion, and an irregularly deposited nidamental tunic, by which the ovum, after exclusion, becomes attached to the ciliated plates beneath the tail of the mother.

The first appearance of development is as a whitish cloud of indeterminate form, spreading over the vitellus, and assuming, as it extends, a reticulated appearance. It seems as if the germ cells had propagated themselves over the superficies of the yolk mass. A discoid portion of the opake layer is defined from the rest, and increases in thickness at its middle part. Its longest diameter is about half the radius of the egg. A depression appears in the centre of this, which passes more and more deeply into the vitellus, and the embryonic spot expands at its margins. The patch next grows heart shaped, and the antennæ, the labrum, mandibles, and abdomen become simultaneously recognisable. The first appearance is a minute median prominence, which becomes the labrum; that part of the mouth which which we find most constantly in the Crustacea. Then the other parts appear in order; the antennæ, at first short and simple processes, increase in length, and their extremities become notched; the mandibles also lengthen and enlarge, particularly in their basal portion; the labrum recedes from between the anterior antennæ, and takes its station between the posterior; the eyes now first make their appearance. All these parts are, at first, slight elevations above the surface of the germ. A cavity is formed behind the labrum, which communicates with the commencement of the œsophagus; the tail or abdomen elongates, and the depression in its surface is converted into the anus; the rest of the alimentary canal is a simple wide sac, which, by the extension of the mucous layer of the germinal membrane, now includes the vitelline mass.

The three anterior pairs of maxillæ begin to show themselves at a little distance behind the mandibles, and afterwards the fourth and fifth pairs; the last increasing in size more rapidly than the rest. Thus, including the eyes and the two antennæ, nine pairs of appendages may now be recognised, of which the two last belong to the thorax: the five posterior pairs of thoracic members, which are not, like the first two, developed into jaws, are produced in regular succession from before backwards from that portion of the body which is turned upwards, or the epimeral elements of the rudimental segments. Each of the legs at its first appearance is exactly similar to the hindermost maxillæ; these, therefore, are retained in the service of manducation by an arrest of development. The ambulatory legs increase inversely with respect to the maxillæ, the anterior soon acquiring four times the length of the posterior. The rudiments of the future branchiæ next appear as small processes from the base of each leg. The seven segments of the third division of the body may now be distinguished by six transverse furrows, and by the rudiments of foliaceous appendages. Part of the cephalic segment above the antennæ is the basis of the great shield which afterwards covers the whole cephalo thorax; it grows upwards and backwards until it meets its fellow along the median line of the dorsal aspect, and so completes the carapace.

The heart appears at first in the shape of a small compressed vesicle, or "punctum saliens," situated near the junction of the anterior and posterior divisions of the body: bloodvessels seem to be prolonged from it, and its pulsation speedily becomes distinguishable.

The nervous system consists at first of eleven pairs of minute white spots, from the anterior of which a short and broad process passes forwards on either side of the œsophagus. The above described stages of development are in progress from the beginning of April to the middle of May.

The whole of the organs continue to approach more nearly to their mature form. The brain, liver, and salivary glands next make their appearance. The outer integument of the body is developed from the ventral to the dorsal aspect, and the yolk-laden intestine is finally, with the heart, walled in by the confluence of the lateral lobes of the integument along the middle line of the back.

The integument is very soft when the animal quits the shell: it subsists, at first, on the remaining portion of the yolk, during which time its coat becomes sufficiently hardened to admit of its moving about in quest of food with more safety. The different appendages increase in length, and more especially the branchiæ, the growth of which is now remarkably rapid. The changes of the interior parts of the animal, with the exception of the development of the sexual organs, consist in a gradual adaptation of parts already formed to their proper functions.

The relative positions of embryo and vitellus are the same in the craw-fish as in the *Daphne pulex* and *Branchipus stagnalis*. The maxillæ present at an early period a considerable resemblance to those of the *Apus*; the legs, at the period when they are devoid of branchial appendages, typify the persistent condition of the Branchiopoda; after the branchiæ are developed, but before they are enclosed in the branchial chamber, the characteristic persistent condition of the respiratory system of the Edriophthalma and Stomapoda is sketched out.

M. M. Audouin and Milne Edwards have shown that the successive changes of development of the nervous system of the craw-fish correspond in like manner with distinct types of formation observed by them in its permanent condition in lower species of the class; thus the double series of ganglions, which first indicate the subœsophageal central part of the nervous system in the embryo craw-fish, is analogous to the permanent state of the nervous system in the mature *Talitrus*. At a more advanced period, the two series of ganglions in the fœtal craw-fish approach the median line and become united together as in the abdominal ganglionic chain in the adult *Cymothoa*. We have seen, that in the brachyurous Crustacea a further concentration takes place by the longitudinal blending together of the whole series of the subœsophageal ganglia, which clearly indicates that the brachyurous Crustacea are

more highly developed than the macrourous species; contrary, however, to the opinion of Dr. Rathké. The eyes are at first sessile in all Crustacea.

It is certain that the moult of the young craw-fish is not at any period accompanied by a marked change in the form of the body, or in the structure and functions of the locomotive members; this Crustacean, in short, undergoes no sudden metamorphosis. The progress of development is not interrupted by arrested phases.

A series of less complete observations on the ova of a species of land crab (*Gecarcinus*), more recently published by Mr. Westwood, lead to the same inference in respect of that species; although the macrourous proportions of the abdomen, and the exposed position of the gills at the base of the thoracic legs, obviously unfitted the larva for land life, and demonstrated the necessity for the parent's migration to the sea. Nevertheless, this accomplished entomologist coincides with Dr. Rathké in the general conclusion, that the Crustacea undergo no metamorphosis, and that the contrary evidence adduced by Slabber and Mr. Thompson must depend on some erroneous observation.

The opposite conclusions of both parties from the phenomena afforded them by the solitary species examined, may be compared with analogous premature generalizations which might have been drawn, in reference to the class of Insects, by the observer of the development of a cock-roach on the one hand, and by the observer of the metamorphoses of a butterfly on the other. As reasonably might the one, after detailing the progressive development of the orthopterous insect, broach the inference that insects underwent no other metamorphosis than the gradual acquisition of wings; and, with equal reason, might the other observer of the wonderful changes of the lepidopterous insect affirm them to be characteristic of all insects. It needs only that each theorist should question the reality of the other's observation to make the parallel complete. The failure of both to arrive by so short and easy a route at the entire truth, inculcates the necessity of acquiring a sufficient foundation, by careful and extensive induction of facts, before proceeding to erect the superstructure of general theory.

With regard to the metamorphosis of the common crab, valuable testimony in confirmation of Mr. Thompson's discovery has been contributed by Capt. Du Cane, R.N. This gentleman obtained crabs with ova under their tails in the month of December, from which the larvæ were produced in the months of March and April. Soon after exclusion this larva casts off its envelope and assumes an appearance which closely corresponds with that zoeiform Crustacean, whose further changes were witnessed by Mr. Thompson, and which he had assured himself was an early or larval state of a common crab. The last form which immediately precedes the assumption of the mature characters corresponds, according to Dr. Thompson, with that of the genus *Megalopa*.

The additional evidence afforded by Capt. Du Cane in proof of the actual metamorphosis of the Crustacean in question, is most acceptable. He affirms a corresponding metamorphosis to occur in the ditchprawn (*Palemon variabilis*) and common shrimp (*Crangon vulgaris*). Dr. Thompson has witnessed similar metamorphoses in the genera *Palinurus*, *Squilla*, *Pagurus*, *Porcellana*, *Galatea*, and the marine species of *Astacus*, as well as in *Palemon* and *Crangon*.

Mr. Couch, a medical gentleman residing on the coast of Cornwall, contributed a paper to the Cornish Natural History Society, three or four years ago, in which he described, with much care and detail, the metamorphoses of the common crab. The nervous system first appears on the ventral aspect of the embryo; at this period it agrees in its arrangement with that which is persistent in the edriophthalmata, and the eyes of the larval crab are likewise now sessile. A second metamorphosis takes place, when the eyes become supported on long and thick peduncles. None of the phenomena are more remarkable than that of the nervous system, where ten pairs of ganglia are consolidated into one great central ganglion in the crab. With respect to the *Maia*, or spider-crab, also, there is a very complete metamorphosis. According to Couch, in both kinds of crab the larva quits the ovum in a form more strictly aquatic than the adult; and this gives us an insight into the curious law of the periodical migrations of the land-crabs of the West Indies to the sea. Brown, in his "History of Jamaica," gives a graphic account of these migrations. About the month of February or March, they may be seen in crowds on their way to the sea-side, impelled thereto in order to deposit their ova in the sea. These ova have been excluded from the oviduct, and are attached, by the nidamental gluten, to the ciliated sub-caudal appendages; and Brown's idea was, that it required the sea to wash them off. But now, as we know that the larval land-crabs are natatory, and more especially fitted for sea-life, we see the necessity for the migration of the parent-crab to that element for oviposition.

Finally, the metamorphosis of another species of shrimp (*Caridina Desmarestii*) have been described with all the requisite care and detail by M. Joly, in the "Annales des Sciences Naturelles" for January, 1843. The development of the ovum up to the period of exclusion and attachment to the maternal ciliated plates, closely corresponds with that described by Rathké in the *Astacus fluviatilis*. The first stages in the formation of the rudimental extremities,—the first steps in the definition of the alimentary canal and circulating system, were likewise the same; the heart was observed to beat thirty-five times in a minute in the embryo *Caridina*. But the formation of the abdomen is anterior to that of the antennæ, the labrum, and the maxillæ; and the ambulatory thoracic legs precede the masticatory pairs in their formation. The young *Caridina*, moreover, is born with only three pairs of jaws, and the representatives of the ambulatory feet are bifid, like those of the *Mysis*, and are at first likewise only in three pairs. The abdominal segments are without any vestige of lamelliform limbs.

The bifid feet of the larva are metamorphosed into auxiliary jaws, and the later bifid thoracic limbs are metamorphosed into the ordinary ambulatory legs. With respect to the branchiæ they are not at all developed when the young Caridina quits the ovum. The first moult takes place three days after exclusion from the egg; the subsequent ecdyses are numerous, and take place at long intervals. It is unquestionable that the Caridina, unlike the Craw-fish, is excluded neither under the form, nor with all the parts which it possesses in its mature shape. It wants, for example, the branchiæ, a certain number of maxillæ, the ambulatory thoracic, and the lamelliform abdominal feet; it possesses neither the squamous tail nor the complex stomach of the mature creature.

The cumulative evidence of the metamorphoses of *Crustacea* can no longer be rejected; but their modifications in different genera, and the number of the exceptions to the law, like that presented by the *Astacus fluviatilis*, are yet to be determined. Here, therefore, is an ample field open to the researches of the original observer, a field which must be diligently and extensively cultivated before it can yield the fruits of true generalisations as to the extent, and nature, and varieties of the metamorphoses in the class of articulate animals which support their bodies on jointed limbs and breathe by gills.

Sufficient has been observed to show, that if certain stages of the development of a higher Crustacean were arrested, and growth alone proceeded with, an animal would result having the characters of the Crustacea of an inferior order. The Crab is "anomourous" before it becomes brachyurous, at an earlier period it is macrourous, and it is "edriophthalmous" before it becomes podophthalmous; and all these stages typify the successive forms of the Crustacea, as they were introduced into this Planet. The entomostracous characters were never overpassed by the Crustacea anterior to the coal measures, and the type of the Macroura did not begin to be departed from until the period of the deposition of the chalk. All the decapod Crustacea are, at first macrourous, or manifest the Oolitic type; and all Brachyura pass through the anomourous or cretaceous type before the proper brachyurous or tertiary character is finally acquired. These resemblances are general, and by no means exact in specific details. No extinct species could be reproduced by arresting the development of any known existing species of Crustacea; and every species of every period was created most perfect in relation to the circumstances and sphere in which it was destined to exist.

CLINICAL LECTURE

ON CASES

OF FISSURED PALATE, TREATED BY OPERATION [STAPHYLORAPHY.]

By R. QUAIN, F.R.S.,

Professor of Clinical Surgery in University College, and Surgeon to University College Hospital.

[Reported by EDMUND CARVER, M.R.C.S., lately House-Surgeon to the Hospital.]

The cases to which I am about to direct your attention to-day are two examples of malformations of the soft palate, which have been, for some time, under your notice. The first case is an example of the most frequent form of the deformity. Its history is as follows:—

William Turner, aged 16, admitted into hospital to be treated for cleft palate. He is of ruddy complexion, somewhat strumous in appearance. His usually had good health, but the cervical lymphatic glands generally are enlarged; and there are now discernible at the side of the neck below the parotid, the scars remaining from suppurating sores, which formed in connexion with inflamed glands two years ago. In the same position the glandular enlargement is at present greatest.

Both his parents are living, and are said to be healthy. They have, in all, eight children; but this boy is the only one affected with any deformity or malformation.

As usual, in such cases, a supposed cause is assigned for the defective state of the palate. It is attributed to a shock which his mother, when pregnant, experienced, in consequence of her husband killing a rabbit in her presence, &c. &c.

In infancy, when he was suckled, the milk flowed from his nostrils "almost as fast" as he drew it into his mouth. But the quantity that thus escaped gradually lessened as he advanced in age, so that by the time he could feed himself, very little passed by the nose. At present none of his food is diverted from its proper course. His pronunciation is very indistinct, in so much that his speech is for the most part unintelligible, except to those who have been accustomed to it.

On examining the throat, the soft palate is found to be divided in its whole length into two equal parts. The parts are red coloured and of good thickness. At the upper or anterior end they are attached close together to the hard palate. From this they diverge at once, and hang wide asunder; but, when upon being bid, the young man makes an effort to swallow, they are observed to approach one another, and even to touch at the lower ends—not in their whole length. The bony palate is entire, except that there is a very small angular notch at the middle of its posterior margin, where the flaps of the velum are close together. The tonsil on the right side is enlarged.

The Operation.—By means of a scalpel, curved on the flat, and double-edged, a free incision was made upon the back part of each of the two halves of the soft palate, at about half an inch from the edge. Some difficulty was experienced in effecting this first step of the operation on the right side, in consequence of the flap of the velum being forcibly drawn outwards to the side of the pharynx, and much narrowed. This happened, especially when the part was touched with the knife; and, at the same time, a narrow depression or dimple was observed on the under surface of the palate, doubtless marking the insertion of the levator palati on the posterior surface, the muscle being in a state of forced contraction.

In the next place, three silk sutures of good thickness were introduced, the lowest through the uvula near its base, the highest about half an inch from the hard palate. They were passed by means of a bent needle, of the kind constructed with a long handle and of rather small size. The needle carrying each suture was made to puncture the left half of the palate on the lower or buccal surface, about a quarter of an inch from its edge. When the velum had been penetrated, the loop of string was caught with a pair of forceps passed back in the cleft, and was so held while the needle was withdrawn. A loop of thin silk was passed in the same way, at the same height, in the opposite division of the velum, and this loop was used to convey the suture-thread from behind forwards into the second half of that structure. The edges of the soft palate being pared, the ends of each of the sutures were drawn together and fastened with a surgeon's knot, a pair of forceps being used to prevent the ends of the threads from slipping while the knot was made.

On the evening of the operation, a degree of nausea came on, which was troublesome till the patient fell asleep. It was probably caused by a little oozing from the incisions on the back of the palate and from its edges. During the first following days, there was a good deal of swelling about the sutures. On the third day the highest of these was removed, and on the day after the other two were cut and withdrawn. It was now found that union had taken place to a considerable extent. The sides of the uvula, with those of the velum contiguous to it, were firmly united; and about midway between this point and the hard palate union was established for the space of about a quarter of an inch. Above and below the last mentioned adhesion there was an opening, and at the lower one of these a slight degree of ulceration was noticed. By the use of solid nitrate of silver, slightly applied when the surface became clean and repeated at intervals, the two openings soon became reduced to the size of pin holes, and these were closed after a heated wire had been passed through.

After the operation, and during several days, the patient was fed, at intervals of about eight hours, with bread in warm milk or beef tea. No solid food was permitted.

Upon trial being made respecting the effect of the operation on the power of articulation, when the holes in the velum were closed, some improvement was evident, and it gradually increased up to the time the patient's attendance at the hospital was discontinued.

Observations.—The first subject for our consideration upon examining a case of this malformation is, its fitness for operation. In order to arrive at a proper conclusion on this point, the extent to which the parts are separated is to be fully taken into account. Respecting Turner, it is said, that with the exception of a notch of trifling extent at the middle of its posterior margin, the hard palate was entire. Of the two parts, likewise, which represented the soft palate, it is stated, that though they are far asunder for the most part, they are close together at their points of connexion with the hard palate; moreover, that they approached and even touched one another at the lower end, when an effort was made to swallow, and the approximation occurred while they were still under observation, while, therefore, the mouth was open, and the effort of deglutition was imperfect. From these circumstances we conclude that there is no loss of substance, or, at all events, that the halves of the fissured structure are sufficiently wide to be brought together and permanently joined.

Now, if in such a case as this the two ununited pieces of the soft palate (so to express the condition of this structure) could, after the abscision of the edges, be held together by means applied at the edges, there would be no undue stretching of any part, inasmuch as the traction would be equally diffused over the entire breadth of the flaps. But this obviously is impossible. The means of keeping the parts in contact, while their adhesion goes on, must be fixed at some distance from the edges,—at least this is true of any means at present used,—and, on this account, the portion only of the velum which is outside the holes for the ligature is stretched. Here, then, is one difficulty to be overcome—the difficulty, namely, that arises from our imperfect means of holding the parts in contact.

Again, in the ordinary state of the fauces of a person afflicted with this malformation, the pieces of the velum hang, as we have seen in the case of Turner, wide apart; and it is only by strong muscular effort that they approach one another. The habitual separation of the flaps is in a great measure owing to the natural elasticity of the structures, whereby they are withdrawn to the more fixed or outer side when the muscular effort which brought them together ceases. But besides this, it will at once be apparent, on examination of the muscles (as you may see this preparation), that the levator palati, in consequence of its inclination inwards from the base of the skull, has necessarily a tendency to draw outwards that side of the divided soft palate with which it is connected. The two muscles draw the parts of the velum asunder. Accordingly, we have seen in the case of Turner, that difficulty was experienced in one step of the operation—that for making an incision on the posterior aspect of the velum,—in consequence of the sides of this part being much narrowed when the muscles were thrown into action by the touch of the instrument. It has happened, moreover, after the removal of the ligatures applied in an operation, that the adhesion which at first appeared to be firm has given way and to all appearance from the influence of muscular action.

With a view to surmount the obstacles to the successful result of "Staphyloraphy" now detailed, modifications have from time to time been made in the operation; or rather additions have been made since the operation was first introduced into surgery. Thus, in order to prevent or diminish the tension or dragging which was occasioned by the ligatures, incisions have been made into the velum outside the ligature holes. And in order to paralyze the muscular action during the healing process, the levator palati, palato-pharyngeus, and palato-glossus muscles have been divided. To Mr. Ferguson we are indebted for showing the necessity of dividing the muscles, and for suggesting the method whereby to attain the object.

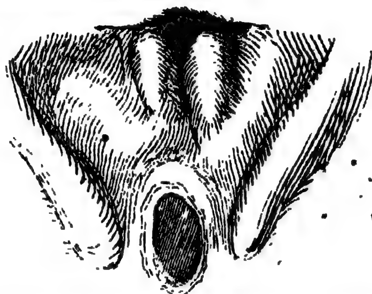
It was then with a view to overcome the obstacles here noticed, that, in the case under our observation, an incision was made on the posterior or upper surface of each side of the velum palati, where the levator joins that structure; and, further, the incision was made of considerable length and depth. By an incision of this kind, not only is the muscle divided, but the over tension of the velum when the ligatures are drawn together is guarded against, as far, at all events, as any separate or independent incision for the purpose would attain this end. The single incision then accomplishes both objects.

But you will remember there is no mention in the detail of the case, which has been read to you, of any muscle having been divided besides the levator palati. The reason is this: I am not satisfied of the necessity or utility of cutting the palato-pharyngeus and palato glossus. These muscles, in the healthy state of the parts, undoubtedly approach each other from opposite sides during deglutition so as to close upon the alimentary bole, and they are, I apprehend, the agents in that approximation of the two halves of the palate which takes place during the attempt to swallow the saliva. We witnessed this fact in Turner; it is common in such cases. Influenced by these considerations, I restrict myself to the division of the levator muscle. In making the incision for this purpose, it will be well to draw the fragment of the velum, by means of the hooked forceps, into the pharynx, for by this means the part to be divided will be stretched, at the same time that the tendency of the muscle to narrow the palate is counteracted.

There is no likelihood, I may add, of inconvenient hæmorrhage during the operation. The internal carotid, the only artery of importance in the neighbourhood, is considerably behind the seat of incision. This preparation illustrates this fact as well as some others I have adduced.

The Sutures.—Much depends on the proper application of the sutures, and much attention is requisite in order that they shall be firmly fixed, retaining the flaps in apposition, but, if possible, without any straining of the tissues. The material used for the sutures, the manner of their insertion, and the method of fastening them, have been almost as various as the surgeons who have undertaken the operation. M. Roux used rather broad ligatures, with very short and very much bent needles. By means of the "needle-carrier" (*porte-aguille*) which I show you, he inserted the needle at the back part of the velum; the ligatures were tied in front. Dieffenbach likewise inserted his short, straight, triangular needles from behind, with a pair of long forceps, adapted for the purpose of holding the needle at such an angle that it readily perforated the velum on its posterior surface. But this surgeon used leaden wire instead of thread, and this substance was inserted into the end of the needle, which was hollowed for the purpose of receiving it. I show you the apparatus. The advantage presumed to be gained by this plan was, that the two ends of the connecting substance admitted of being twisted or untwisted, so that the surgeon had it in his power to augment or diminish its tightness at will, whereas the silk thread is fixed once for all. An ingenious contrivance for fastening the usual silk suture has been used by Sir Philip Crampton, namely, a little ring of metal, which received the two ends of the ligature, and which, after these had been drawn together in the proper degree, was fastened by pressure with a pair of strong forceps. (See *Dublin Journal of Medical Science*, Vol. XXII., p. 324.) Instead of the metallic ring, Mr. Ferguson forms a loop on one side of the ligature, into which he inserts the opposite end of this, and then ties the knot. Again the quilled suture has been resorted to. In the case of Turner, the surgeon's knot was effectual. The first part of the tie, as is stated in the narrative, was prevented from slipping by means of a pair of forceps. The variety of expedients resorted to serves to show the great importance which attaches to this part of the operation, and the difficulty as well of accomplishing the object in a perfectly satisfactory manner,—a difficulty arising out of the depth of the part operated on, and the narrowness of the space in which the surgeon acts.

I turn, in the next place, to the question how the patient should be treated after the operation. Professor Roux, who invented the operation, enforced rigid abstinence during several days. His precept was this:—"After the operation, and for the space of four or five days, the person operated on ought neither to speak a single word, nor eat nor drink, and ought not even to make the movement of deglutition necessary to swallow the saliva."—[Mémoire sur la Staphyloraphie ou Suture du Voile du Palais. 2nd Edition, page [illegible].] Putting out of question the suffering occasioned by adherence to this rule, the constitutional state it is calculated to induce, cannot, I think, be favourable for the proper elaboration of the adhesive process by which the cure is to be effected. Besides, the number of persons to whom the operation would be applicable would be much limited if the observance of that rule were indispensable, for all young persons and delicate females would be excluded. Happily, however, more recent experience (the important suggestion being due to Sir P. Crampton) has, in a great measure, proved that a fair allowance of food after the operation does not interfere with the favourable progress of the case. But, supposing for a moment the present amount of experience to be insufficient to establish the propriety of allowing the patient a moderate quantity of food, we may, I think, still show the presumed necessity for entire abstinence to be not well founded. For what, in fact, is the position of the two halves of the fissured palate during deglutition? We have seen already that they were drawn together during the muscular effort which belongs to that process. It was, indeed, the observation of this very fact that first suggested to the mind of M. Roux the possibility of uniting the two pieces by suture. He states that, while he was engaged in inspecting the mouth of the medical student (Mr. Stephenson) on whom the operation was first performed, but without contemplating the possibility of affording any relief for the malforma-



tion, he happened to observe, "during an involuntary movement of the isthmus faucium, rendered necessary, doubtless, by the necessity of swallowing a little saliva, that the two parts of the velum, for an instant, came into contact by their free borders." —("Mémoire," &c. P. 12.)—"This," continues M. Roux, "was a flash of light for me." From this single fact he inferred the possibility of effecting the closure of the palate by operative procedure. Now, seeing that such is the effect of the effort of deglutition on the parts of the palate before they are brought together, why should there be so much apprehension respecting that act after the sutures have been inserted? It is, to be sure, highly probable that frequent disturbance of the parts would interfere with the process of adhesion; and it is also likely that solid food would be injurious by its actual pressure on the velum as well as on account of the continued movement of the muscles during mastication. But this would be an argument not so much for entire starvation as for confining the patient to the use of soft food administered at considerable intervals. The course, therefore, that I recommend is this:—The patient is to take a meal about an hour before the operation, that space of time being allowed to intervene lest vomiting should be brought on by the necessary interference with the fauces if the stomach were encumbered with recently taken food. Some nutriment may subsequently be allowed in a few hours, six or eight, according to circumstances, and repeated every eight hours. Modifications of the plan will, of course, be made according to circumstances, including the age and strength of the patient. For example, upon the continuance of oozing of blood from the edges and back part of the velum, as it has a tendency, after the operation has been completed, to cause a degree of nausea, or even sickness,—(this occurred in the patient, Turner,)—I prefer delaying the concluding step of the operation for a couple of hours to completing it at once. This pause is allowed where there only remains of the operation to draw the ligatures from one side of the velum into the other, and to tie the knots. In this interval cold water ought to be often used to wash out the throat, and some soft nutritious food should be given; after which the parts are cleansed of clots and put together. The last step of the proceeding is advantageously timed towards the close of the day, (while, however, there is still good daylight,) for then food need not be taken again till breakfast on the following morning. The aliment is to consist of milk, with tea or coffee, if desired, or beef-tea thickened with bread-crumb, arrow-root, or other farinaceous substance; and it is to be continued of the same kind during several days.

The Effect of the Operation on the Speech.

It must not be expected that a person who, during his preceding life, has spoken very indistinctly, shall at once assume all the consequences of the possession of a complete organ. Every one's experience furnishes him with sufficient proof, that even where there is no malformation whatever, at least none that is appreciable, much practice, as well as aptitude, is necessary to the attainment of really distinct articulation. From the operation, even when completely successful, all that can properly be expected is, to place the patient in such a condition, that he may effectively practice to attain the art of speaking with distinctness. The lad Turner, it should be stated, had less than average facility in speaking, even as compared with other persons affected with the same malformation. He failed especially in pronouncing letters which are formed with the tip of the tongue, and with the aid of the teeth. Hence such words as "sister," "Thames," &c., when sounded in his way, were scarcely to be recognised. It seemed, in watching him, as if the muscles of the fauces were engaged in preventing the voice from passing through the nose, while those at the anterior part of the mouth were not called into action at all, or very ineffectually. Notwithstanding, however, the manifest want of aptitude in the patient, the amendment, which is stated in the narrative read to you to have been apparent when the sides of the palate had been completely closed, became a clear improvement after he had been engaged with his family in practising the pronunciation of some words, of which Mr. Jackson, his dresser, kindly gave him a list. The improvement, as might be expected, is more decided and rapid when the person is placed under the instruction of one of those gentlemen—(Mr Poett, for example)—who devote themselves to correcting faults of pronunciation. But, from this advantage hospital patients are excluded by the expense.

So far we have been engaged with a case of "cleft palate," in which the malformation consisted only in the division of the velum palati without any complication. The second case of imperfect palate, which was under your observation at the same time with the foregoing one, comes now to be noticed. This is its history, abridged from Mr. Gay's report in the Case-book:—

J. W., a female, aged 23, admitted into hospital on account of a congenital deficiency in the palate. When an infant, during the act of sucking, the milk used to pass into her nose. She could not speak at all until she was two years old, and then very indistinctly. In her childhood she was able to whistle and sing a little, and could blow out a candle. She could not, and cannot now, pronounce the letters *g, h, j, k, q, t*; but still she speaks with tolerable clearness. Her general health has not been very good. She has suffered some years from irregular menstruation.

The appearance of the soft palate is represented in this sketch.

The soft palate is entire at its middle, but the uvula is fissured, the two parts hanging close together, and at the upper end there is an oval opening measuring more than half an inch in length. At each side is an elongated elevation upon the surface of the velum; this, at first sight, seemed to me to result from increased thickness, owing probably to the presence here of greater amount of muscular substance; but on examining it with the finger, I came to the conclusion, that the appearance arose from a degree of looseness in the part, caused by the position into which it fell when under examination. Except at the lower part of the uvula, the whole structure was much thinner and paler than usual, and this condition was especially apparent at the edges of the oval opening, which seemed to be formed of nothing more than the double mucous membrane.

The back part of the hard palate is defective, being widely notched up to within an inch and a half of the incisor teeth. The patient states, that the opening in the velum was originally round, and about the size of a pea, and that it had no more than this size till about two years ago, when an operation was performed by a surgeon with a view to close it. According to her own account, she has since that time experienced more difficulty in pronouncing words. She adds, that while at all times she was obliged to be careful in eating, she has, within the period referred to, been compelled to be much more so; and now, unless she holds her head up when in the act of drinking, the fluid passes into her nostrils.

The Treatment of the Case.—A single suture was passed through the uvula after the edges had been pared. The parts became united in a couple of days without any difficulty. At a subsequent period, a stopper of India-rubber—"obturator," as it is termed in more dignified language—was inserted into the aperture, and the patient then left the hospital. Two months afterwards, the following entry was made in the Case-book:—"She attended for inspection this morning. She cannot keep the stopper in its place for more than four days at a time, her mouth then becoming sore; she has no difficulty in removing and replacing it. Her pronunciation is evidently more distinct. She can pronounce all the letters that she previously could not, with the exception of the letter *t*."

To judge the better respecting the peculiarities presented by this case, it should be understood that the variety noticeable in the malformations of the palate usually consists in the more or less extensive deficiency of the hard palate, whereby the nasal fossæ open into the mouth; the soft palate being at the same time cleft, and its parts wide asunder in their whole length. These preparations are different degrees of the deformity.

Comparing with these the palate in the case of J. W., the deformity is at once seen to be altogether different in kind. The latter is, indeed, in some respects, very unusual, if not peculiar in its characters. The hard palate is defective at its back part, but unlike the condition in the preparations, the defect in the bone is only discovered with the finger, for the investing membranous structure being continued uninterruptedly across the roof of the mouth, it forms a complete barrier between the nasal and buccal cavities. Practically, then, the defect in the bone is of no material importance, as the process of deglutition, and the production of speech, would not thereby be interfered with.

But, as regards the imperfections of the soft palate, there could have been no doubt that the edges of the lower fissure might be united by suture, the parts being fully developed in all respects. On the contrary, the velum was so thin around the upper opening, that an operation would most probably fail in consequence of defective nutrition. All question, however, as to an operation on the part, was set to rest in my mind, by the consideration that there was here not a mere fissure or want of the union of parts otherwise complete, but an actual loss of substance. Under these circumstances, after the lower fissure had been closed, I advised the use of a simple form of obturator for the opening which still remained. But, had the soft palate been of the usual thickness, and had there been also no material loss of substance around the opening, sutures would have been applied with every probability of a favourable result; and, considering that in this case, a large part of the velum was perfect, it would not, in my opinion, have been necessary to attempt the division of any muscle. An incision to a considerable depth, outside the ligature holes, would, however, be useful on the principle explained at a former part of this lecture, viz., to diminish the effect of traction, and the consequent tension of the parts.

ORIGINAL CONTRIBUTIONS.

ON THE EMPLOYMENT OF ETHER AND CHLOROFORM IN CASES OF MIDWIFERY.

By CHARLES WALLER, M.D.
Obstetric Physician, and Professor of Midwifery to St. Thomas's Hospital.

The time appears now to have arrived, when a calm and deliberate opinion may be expressed, as to the safety or propriety of employing anæsthetic agency in the practice of midwifery. The intense excitement produced by the astounding announcement, that a female might be relieved from the pains and the perils of child-birth, by a certain and safe remedy, has, to a great extent, subsided, the charm of novelty has passed away, many authenticated cases, with their results, have been reported, and we are therefore in a position to form something like a correct judgment, inasmuch as we have *facts* upon which our calculations may be founded; and, although I unhesitatingly confess, that I have not considered it to be my duty to employ means of such acknowledged power, unless there were some very pressing necessity for their use; yet, as these

published facts become the common property of the Profession, I offer no apology for making the experience of others the basis of my own practical deductions.

And here I would observe *in limine*, that the observations I am about to make have no reference whatever to the use of anæsthetic agents where severe operations are required; I leave this to those more conversant with the subject than myself. The condition of the body, in a state of disease requiring a surgical operation, is, to my mind, so entirely different from that which generally obtains in the parturient female, that no analogy can be fairly drawn between them. In the former there is often great prostration of the vital powers, with a high and painful degree of nervous susceptibility as a consequence of such debility; added to which, the *fear* of the operation required has a most injurious effect, inducing the patient to postpone the dreaded occurrence, until the disease has assumed a most formidable character. Again: the *shock* of the operation, in such individuals, may retard or altogether prevent their recovery. It should also be remembered, that some chirurgical operations require to be performed with such extreme care, that an involuntary movement might be productive of serious mischief. This observation applies with more than ordinary force where an infant or a young child is the subject of such treatment. I do not, however, wish to be understood as advocating the use of ether or chloroform, indiscriminately before performing surgical operations, experience having demonstrated, that dangerous and even fatal effects have resulted from such administration.

Widely different, under ordinary circumstances, is the condition of the parturient female: in perfect health, the bodily powers not diminished by long-continued suffering, the pain not the result of organic disease, but merely produced by the altered physiological condition of the uterus, usually unattended with danger, although it may be severe and prolonged: the strength, recruited by intervals of comparative, if not of perfect ease. Under such circumstances, I apprehend that every man of prudence would pause before he exhibits a medicine which is occasionally followed by the most disastrous results.

Various objections have been made to the employment of anæsthetic remedies in midwifery; some of them scarcely tenable, whilst others are of more solid weight. Some have objected, on religious grounds, believing that the curse pronounced on our common mother, on her dismissal from the garden of Eden, "In sorrow shalt thou bring forth," was meant to be enduring; and that any attempt to alleviate the pain attendant upon human parturition was in direct contravention and in open rebellion to the will of the Almighty. I cannot support such an opinion as this, as, by so doing, I must of necessity deprecate the attempt to relieve any of the numerous "ills which flesh is heir too," all of which resulted from man's primæval disobedience. The words of our Saviour, "they that be whole have no need of a physician, but they that be sick;" and his constant practice of "healing all manner of "sicknesses" sufficiently answer such an objection as the one under consideration.

Whilst I thus express myself, however, let it not be supposed that I am satisfied with the "answer" to the religious objections first published by the Professor of Midwifery in the University of Edinburgh, and since acquiesced in by some in our own country. His attempt to explain away the generally received import of the Hebrew word *etzebh*, translated "sorrow," in our common English version, is, to my mind, exceedingly unsatisfactory. In noticing the circumstances under which the sentence was pronounced, he observes, "the curse" is triple. I am at a loss to conceive what punishment or "curse" could be implied in the words which the learned Professor considers to be the proper translation of the Hebrew word *etzebh*, "with muscular effort," or "with toil," shalt thou bring forth. In a great majority of instances this "muscular effort" is only required for a few hours at the most, and not continuously, but with intervals of rest from muscular effort, if not too long prolonged, is attended with pleasurable rather than with painful sensations. Again, I apprehend, that the distinct meaning of the "curse" may fairly be inferred by the effects which immediately followed its proclamation,—and what were these? In the first place, intense suffering. To prove this, it is only necessary to refer to the various texts quoted by the Professor himself, which clearly demonstrate, that, under almost an endless variety of circumstances, whenever a state of unusual suffering was described or predicted, reference was made to the state of a parturient female. The following expressions will suffice:—"Pains"—pangs"—"fear"—"anguish"—sorrows"—being "in sorrow, and crying out in her pangs."

But the puerperal period was, at this early age, not a state of suffering only, but a state of danger. Rachel died immediately after giving birth to Benjamin? But, some may say, why multiply these instances—who doubts their truth? I reply, simply to show that *mere* muscular effort was not intended, but that pain and danger immediately followed the utterance of the "curse."

Let us now inquire into the physiological effects produced by the inhalation of ether or chloroform, and carefully examine the results which have followed their exhibition, that we may arrive at a satisfactory conclusion regarding the perfect freedom from danger claimed by many who have advocated this course of proceeding. If it be proved, that in many cases, serious, dangerous, and even fatal symptoms have ensued, then it requires but little argumentation to convince a thoughtful mind, that urgent and pressing necessity can alone justify the use of remedies which are capable of producing such disastrous results—no one will deny that such occurrences have taken place: the time has gone by, when it can be said, "there is no evidence to show that the ether has any bad influence on the mother." But, what is the effect produced by these anæsthetic agents on the general system? The immediate effect of ethereal inhalation is twofold: in the first place, the contact of atmospheric air with the blood circulating in the pulmonary capillaries is prevented; but this is not all, for, in addition to this negative evil, of shutting out air fitted for the due and proper performance of the respiratory function, that which is positively deleterious is introduced in its stead, and, in point of fact, it is upon the action of this injurious principle that anæsthesia depends. The blood is charged with carbon, and becomes, at *first*, unfitted to sustain the actions of animal life; and, if the process be carried too far, or continued too long, the organic actions are similarly affected. In the one case, there is loss of sensation and voluntary motion; in the other, the respiratory and circulatory systems suffer, and death is the result.

In experiments upon animals I have noticed the three following results: first, agitation, amounting, in some cases, to convulsions; secondly, anæsthesia; thirdly, death, and this not preceded by any symptom indicating the approach of a fatal termination nor as a consequence of a long continued use of the chloroform. Can it with truth be asserted, that these results have only been witnessed in the inferior animals, and never observed in the human subject? Would that experience (the best of teachers) would warrant such a statement. The records of cases, published in our public journals, testify to the contrary; death has occurred after a very short inhalation, in some cases suddenly, in others preceded by convulsions. In my own practice, I have seen delirium produced of so violent a character as to render the patient for some time uncontrolable. In another case, a very "horrible feeling of oppression" about the præcordium was produced, attended with a feeling as though the "heart would burst," then followed unconsciousness. On her reviving from this state, the lower extremities were paralyzed to a considerable extent, and for the two following days this lady was unable to move about. This happened about two years ago, and from that period my patient informs she has never been in perfect health. In two other instances the attempt at inhalation produced such a feeling of suffocation that it could not be persevered in. Two cases of death, one during, the other immediately following labour, have been reported to me; another wherein serious hæmorrhage occurred. Dr. Montgomery states that in his own practice he has known the proper muscular action of the uterus for a time suspended.

I am fully aware that a ready, though somewhat flippant reply may be offered; it may be said, these cases were exceptions to the general rule, or the remedy was improperly administered, or that a too powerful dose was employed. All this, to a certain extent, may be true, but still the practical difficulty remains. I know that, where every reasonable precaution has been taken, hurtful and fatal consequences have followed, and this is sufficient to prevent *me* from employing these agents indiscriminately, and without a conscientious belief that of two evils I was choosing the least. Having proceeded thus far, it will scarcely be necessary to add, that in cases of strictly natural labour, where nothing is to be gained but unconsciousness of pain, and that at the risks before alluded to, I should never consider myself justified in making use of means which can only accomplish the object intended by reducing the patient to a state of mere organic existence by paralysing those portions of the brain from whence the nerves of sensation and voluntary motion derive their influence; and especially since the fact is well established, that occasionally the nerves of respiration and circulation are alike paralysed, when death must inevitably ensue.

It is extremely difficult to determine with precision what is the effect of this narcotism upon the action of the uterus. If we could credit the accounts which have been published from time to time, the following conclusion must necessarily follow: that the system generally, and the parturient organs locally, are made so remarkably tractable, that they accommodate themselves to the exigencies of the peculiar case, and to the wishes of the practitioner. Thus we are told, that under the use of chloroform the most opposite effects have been produced; in the one instance it will contract, in another it will relax; in a third, where everything is going favourably, no special action ensues. The inhalation is, therefore, proper, whether we wish to expedite labour, to prevent hæmorrhage, or to render the uterus quiet for the purpose of introducing the hand in cases of difficult turning. Again, it has been said that perfect insensibility on the part of the patient is a great boon to the practitioner in cases of instrumental midwifery, inasmuch as the operation is unattended with pain, and no sudden movement of the female will obstruct the progress of the delivery. During an extensive midwifery practice of nearly thirty years, I do not recollect ever to have been resisted by these movements except once, whilst on the other hand I cannot but consider that perfect susceptibility to pain may sometimes prevent the infliction of serious injury upon the maternal soft parts. The teachers of midwifery should remember, however simple and easy obstetric operations have become to them in consequence of their frequent performance, that their recommendations and opinions will influence the practice of those who have not, and never can have the same opportunities; and that what may be perfectly safe in the hands of the few, may not be equally so in the hands of the many.

As regards myself, I have a very decided objection to the use of chloroform in instrumental midwifery, especially where craniotomy is performed in the more aggravated cases of pelvic deformity, where it often happens that a rough edge of fœtal bone comes into contact with the soft parts of the mother, and to which the attention of the Practitioner is probably first directed by a complaint that "something is scratching." I must not, however, forget that the production of anæsthesia is destined to explode that barbarous operation, and that henceforth patients, whose cases require craniotomy, are to be placed under the influence of chloroform, the infant turned, and violently dragged through the

contracted pelvis; as if, with the loss of sensation, there would be no danger of injuring the soft parts by the exercise of any degree of force necessary for the accomplishment of the desired object!!

From the foregoing observations the following conclusions may be fairly deduced:—

1st. That the inhalation of ether and chloroform has been followed by injurious and fatal results.

2nd. That in natural labours no reason exists for the employment of a remedy, the efficacy of which is at least doubtful, and its action often hurtful.

3rd. That the action of the uterus is sometimes suspended; but the published accounts are so contradictory, that it is impossible to form an accurate judgment on this point.

4th. That the production of anæsthesia in operative midwifery is likely to be injurious rather than beneficial.

I will merely add, in conclusion, that the only cases which appear to justify inhalation are the following:—

1st. Where there is an unusual degree of nervous excitability and sensitiveness. I should, however, not be inclined to produce perfect insensibility, but should be satisfied with *diminishing* the powers of sensation.

2nd. Where there are severe muscular pains in the neighbourhood of the uterus, interfering with its action. This state has been well described by Dr. Power under the generic term "myopathia," of which he describes several varieties. In these cases I should recommend moderate inhalation, and not the production of perfect narcotism.

3rd. In very difficult cases of turning, some benefit might *possibly* be obtained, although in many instances, a dangerous amount of force might (unless great care be taken) be employed in extracting the child when the patient is in a state of insensibility.

Finsbury square, Oct. 27, 1849.

RESEARCHES ON INVOLUNTARY SEMINAL DISCHARGES, AND THE DISORDERS ATTENDING THEM.

(Continued from page 86.)

By H. J. M'DOUGALL, Surgeon, Fellow of the Royal Medical and Chirurgical Society, formerly House-Surgeon to University College Hospital.

In the following case, which I translate from the work of M. Donné, on the Microscope, the patient, a medical man, describes so fully and accurately the distressing mental feelings to which I alluded in my last paper, that I make no apology for relating it, as a prelude to cases of the same description which have come under my own notice. M. Donné's high reputation, as a microscopic observer, and his being, at first, opposed to M. Lallemand's views are additional reasons for drawing a case from such a source, as it cannot be suspected of prejudice. The details are related in the form of a letter, addressed to M. Donné:—"You promised me, my dear friend, to become the confidant of all my troubles. Do not expect the brilliant and dramatic misfortunes of a modern hero, of romance; I have only to recount one sad, continuous, monotonous, overwhelming misery. I shall not enter into a detail of the sufferings of my stomach; they are everything that you have ever observed, everything that you have ever read, and much more besides. But you cannot conceive with what unfortunate facility the sufferings of my stomach pass to my head, and how they disorder all my relations in life. Hence I suffer less still in the stomach than in the head. After sleep, I experience, for an hour at least, a sense of cerebral weight, with congestion, so nearly resembling drunkenness, as to have been mistaken for it. If I have taken food slightly too stimulating, I feel more or less intense general irritability, sometimes extreme, with itching in the skin, and especially the scalp, susceptibility to the slightest light or least noise continued anxiety and agitation, unfortunate inclination to quarrelling and revenge, furious rage on the least contradiction, and nightmare instead of sleep. This is not a fanciful picture, but a faithful portrait. If I have, on the other hand, taken food a little too mild, I fall into a deplorable state of depression,—a great body without a mind; and when one of the attacks of hunger to which I am so subject comes on, I experience pain and deep exhaustion, as though my being were dissolved. After such violent attacks, so frequent during so many years,—after the sad isolation in which I have lived,—how can my brain have escaped being injured, exhausted, paralysed? Hence, heat and cold, drought and damp, all are to me jarring and painful. I have also moments when everything enrages me. At the least trouble I become suddenly flushed, trembling, and stupid. My intellect vacillates like my motions; and this embarrassment, of which I am ashamed, and which I cannot conquer, increases still more if any one observes me. On these occasions I might indeed be taken for an imbecile and a coward. . . . . Believe me, it is very sad, and very humiliating, to feel all one's faculties, when most required, and notwithstanding every effort to retain them, escape suddenly, and to feel oneself falling into such a state of imbecility at the age of firmness and vigour. The idiot, at all events, has no knowledge of his idiotcy. . . . . If my sufferings pass rapidly from my stomach to my brain, they are transmitted no less rapidly from my brain to my countenance. Everything which deranges my stomach and brain, disorders my countenance also. If exposed for a short time to sharp cold, my features become contracted, and my whole face resembles a vast chilblain. After great heat, when the air is overcharged with electricity, especially after fatigue, my features show disorder and agitation with congestion. In damp weather they are pallid, and show my depression. During the short intervals my attacks grant me, my countenance appears jaded, with an air of timidity and stolid awkwardness. This expression of face follows my disease as its shadow attends my body. It appeared and developed itself with my malady, and will yield and end only with it. Wherever I go people laugh and point at me. I hear indirect mockery uttered around me, and must unceasingly submit to a thousand marks of contempt sufficiently evident for me not to be able to avoid seeing them, but not evident enough to permit of my being revenged. It is true, that these mockeries, like the physical disorder, belong to my disease, for I have always noticed the three circumstances—disease, physical disorder, mockery—follow constantly in the same order, and with the same variations. The appearance of misery and awkwardness must be striking indeed, that so many people should receive so powerful an impression from it, and that they should manifest that impression immediately, spontaneously, and as if the same idea had animated them. All these mockeries render me more susceptible of ridicule and more ridiculous."

I need not make any further extracts to complete this picture, at the time of writing which, the patient himself was not aware of the cause of his disorder. This it was reserved for M. Donné to discover and to treat.

The following case is that of a young man, twenty two years of age, also studying medicine. Premising that he contracted the habit of masturbation at school before puberty, and subsequently practised it frequently for about three years, I give his own description as contained in his consultation letter. After various unsuccessful attempts and numerous relapses, he succeeded in abandoning masturbation. He says:—

"This was more than three years since, and precisely as I discontinued engineering, and entered the medical profession, my more serious troubles began. I had a long-continued illness, with ague, and then another, of neuralgia; but a visit to the country restored me for a time. I began to suffer more and more from involuntary emissions. Last summer I returned into the country, to prepare myself for the then coming winter session, and, in apparently good health, I went to London. From the first day until Christmas I worked *very hard*, both in the dissecting-room and in my own rooms. A fortnight after entrance, I was seized with an alarming giddiness at lecture, and was obliged to leave the theatre. It threatened to return once or twice, but I did not allow it to interfere with my plan of study. Shortly before Christmas, my nervous system evidently began to give way. I got so morbidly sensitive as to fancy, (in spite of my better knowledge,) that a merely casual remark at lecture applied to my own case, &c. All at once, if I caught a student's eye wandering to me, I have felt the colour flying into my face. At dinner it was worse, and I knew it to be a matter of observation. In brief, Sir, I can give you no idea, nor can I bear to recapitulate the misery I suffered. I missed lectures, *read in-doors*, and walked vigorously for an hour before dinner. Still I was very little better, and suffered occasionally from dyspepsia. I have passed the summer at home with very little benefit. The nervous affection of the heart returns, and I seldom feel *well*. I am distressingly irritable at times,—have no great appetite,—suffer much from dyspepsia,—have a constantly irregular pulse,—a peculiarly disagreeable sound, as of a distended vessel, in the neighbourhood of the right auditory canal. Dizziness, languor, *muscæ volitantes*, also contribute to make me wretched. My personal appearance is but slightly improved; but, worst of all, the atonic condition of my genital organs is the same, or, if I may judge by the frequency of involuntary emissions, my state is worse than ever. I have *entirely renounced* the habit of masturbation for a long time."

The above is one of the common cases, in which immediate ill effects do not follow masturbation. The patient acquired the habit before puberty,—by no means an uncommon circumstance, and, in my opinion, very pernicious in its after effects,—and continued it for several years, when the involuntary emissions commenced, after which his health first began to be seriously affected. Probably the alteration of his habits, from an active life to a course of close study, assisted materially in deteriorating his health.

In another case, masturbation for a short time, followed by severe study, had most injurious effects. The patient, who had taken high honours at a public school, after describing his bodily sufferings, and deploring the loss of his sexual powers, expresses himself as follows:—

I complain more of my mind than of my body. I am perfectly apathetic, and am subject to a most overwhelming timidity in company. I am in a wretched state always at meal times. I never speak a word, but yet I like to have some one in my room to talk to. I have never been into society at all, which probably is the reason. *I cannot look any one in the face steadily*, and am very much afraid of contempt or ridicule. I have no energy to do anything, and no resolution."

In another case, the patient, a clergyman, exhibited the restlessness arising from spermatorrhœa, in a very marked degree. The origin of the complaint was masturbation in this case also, and the patient complained of being constantly persecuted by a feeling of the deepest and most acute remorse. He could not remain five minutes in the same occupation, and, from his attacks of passionate bewailment, he was a source of very serious uneasiness to his friends. He never slept at night, sleep being partly kept off by the great irritability of his bladder, which required relief every hour at least.

It is astonishing, how rapidly, in these well-marked cases, all the mental symptoms disappear after the arrest of the pollutions. Indeed, in some cases, their previous condition becomes almost a matter of unbelief to the patients after recovery. In the last case to which I have alluded, the patient, in whom I was much interested, and of whom I saw more than is usual in such cases, coolly looked back on his condition after he had recovered, and discussed what he remembered of his feelings, and the motives of his actions. He admitted that he had frequently thought of ridding himself of existence by suicide, but that he had not sufficient moral courage to perform the fatal act. I believe this state of feeling to be by no means uncommon.

I might add extracts enough, from cases either drawn up by the sufferers themselves, or entered in my note book from their dictation, to fill a whole

number of the *Medical Times*. There is, however, a great sameness in such statements, and I think sufficient has already been brought forward to illustrate the chief points to which I called attention in my last communication.

In my next, I shall consider the effects produced by spermatorrhœa on the stomach and intestines.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

Our Medical Session commenced yesterday, under more promising auspices than could have been expected, after the distress and agitation of the last two years. The attendance of pupils was much greater than we had anticipated, and the number of distinguished practitioners, from all quarters of the capital, helped to fill up any vacancies which were left by the timid or tardy students.

The official programme of the Faculty is generally, as you know, simple in the extreme—an opening discourse by one of the Professors, closed by a distribution of prizes.

On the present occasion the usual routine was slightly interrupted by the reading of a letter of excuse from M. Dumas, whose recent appointment as Minister of Commerce prevented him from being present among his brother Professors. This letter, in which a just tribute of praise was freely bestowed on the students for their admirable conduct during the cholera, was received with enthusiastic applause.

The opening discourse of M. Denonvilliers was exclusively devoted to the eulogium of Professor Blandin, removed by a premature death, in the fiftieth year of his age, on the 16th of April last. Blandin was one of the few eminent men whose names still continued to render the Parisian school illustrious, after the irreparable losses of the last ten years; and we look in vain, amidst the rising generation of young surgeons, for one who may worthily fill his place.

M. Berard, the new Dean of the Faculty, delivered an interesting discourse on the proposed changes in Medical Institutions, alluding more particularly to the threatened attack on the "Concours," to the abolition of officers of health, and to quackery. He would ever defend the Concours as one of the principal causes of the eminence which the French School of Medicine had attained. Though retired from practice, and, consequently, a disinterested party, he was prepared to insist on a law for the protection of legally-qualified medical men from the plague of charlatanism. Finally, he was also prepared to support the project for suppressing the second order of Practitioners in France, although such suppression must be a fatal blow to the preparatory schools of medicine. M. Berard then explained the measures which he had employed for obtaining recompenses for the students distinguished during the cholera. No solicitation, indeed, had been requisite, and the Minister had shown himself so liberal that the Dean thought it prudent rather to moderate than excite his munificence. One interne received the cross of the legion of honour; fifty pupils were decorated with medals, and three, in addition to the medal, received their inscriptions *gratis*.

This discourse of the Dean, who appears to be as popular amongst the students as Orfila was detested by them, elicited marks of universal applause.

But the honours alluded to by Professor Berard are not the only ones which have been distributed to the members of the Medical Profession for cholera service. Professor Rostan, M. Merlier, M. Boudin, of the Roule, and M. Worms, of Gros-Caillou, have been promoted to the rank of officers of the Legion of Honour; six military surgeons and two apothecaries are named as chevaliers twelve physicians, one from each of the twelve arrondissements, are likewise decorated, and 782 medals have been distributed amongst physicians, students, Sisters of Charity, and other persons whose conduct during the epidemic appeared to merit reward. It is an example worthy of imitation amongst you, and the opportunity is propitious; but in England, for some reasons difficult to discover, no one is thought worthy of a distinction unless he has worn epaulettes.

The cholera, I regret to say, still continues its ravages in the south of France and in Africa. I have just seen a letter from the Director of the Military Hospital at Oran, in which it is mentioned that 400 patients and 29 infirmary attendants have already been cut off by the disease. The Spanish attendants refuse to bury the dead, and it has been necessary to send for the soldiers under punishment in the condemned companies, to perform this last duty.

SELECTIONS FROM FOREIGN JOURNALS.

PHYSIOLOGICAL AND PATHOLOGICAL INQUIRIES INTO THE NATURE OF PHLEBITIS.

By Dr. C. A. MEINEL.

The specific characters of phlebitis are very imperfectly understood.

Fourteen experiments on this subject were made by the author at the Physiological Institution of Gottingen, under the direction of Professor Vogel. They consisted in the section of the veins, in the injection of different substances into them, (water, starch, sand, pus, &c.,) the introduction of foreign bodies, (as pieces of wood, wire, needles, quills,) and in irritation of the walls of the vein, or pricking it by a wire.

Dr. Meinel considers, that the anatomical researches of Professor Henle are too minute in a pathological point of view. The external coat of the vein is cellular, containing vessels and nerves. The middle tunic is produced almost insensibly from this, and is formed by elastic fibres disposed transversely (the annular or circular coat). On examining more interiorly, the number of the elastic fibres of the vessel diminish in number, and are replaced by fibrillæ united to the cellular tissue, assuming a longitudinal direction; this is the internal tunic which seems in some degree amorphous. As for the epithelial membrane, according to the Author, it is only seen in the recent vein immediately after death, and does not appear all throughout.

It is generally agreed, that the nutritious vessels penetrate as far as the middle tunic; but in a small degree, and without forming any capillary network; they simply follow the course of the fibres. Vessels, whether in the sound state or in the diseased conditions of the veins, were never seen by Meinel, which agrees with the observations of Henle, Vogel, and others.

Our author raises his voice against the pretended analogy between the internal membrane of vessels, and the serous tissues; for the latter are formed by an ample cellular tissue permeated largely by vessels and nerves. Nothing of the kind is to be discovered in the internal coat of the blood-vessels: it is, therefore, a fallacy, to assume this analogy, as illustrative of the facility of inflammation of the internal coat.

Avoiding the discussion of what is meant by inflammation, our author submits the two following propositions for our consideration;—

1. What are the changes undergone by the various tissues during the morbid process, termed inflammation?

2. What is the nature of the exudation in the interior of the vessels?

In answer to the first proposition, it is useful to consider attentively, the changes in the wound made by venesection. Our Author recites the various researches made on this topic, and in particular those of Trousseau, and Pigot, so early as 1827; and he asserts, with them, that in wounds of the veins, the internal tunic is altogether passive; that it never exhibits any injection nor change in texture; that it is not in the least degree involved in the process of organization, which is effected solely in the coagulum and the walls of the external tunic. These observations were confirmed by experiments on various animals; the internal tunic was invariably found by him uninjured, even by the action of the most powerful irritants, while the cellular membrane, and the exterior laminæ of the middle tunic, were observed to be red, swollen, and softened; often, indeed, it was easy to detach the middle and external tunics from each other, a sufficient proof of softening. The internal coat, therefore, can never be said to be the subject of inflammation.

The remarks just now made supply an answer to the second proposition; for, if there be no inflammation in the internal tunic, how can there be any exudation in the interior of the vessels? The Author replies in the negative, for he does not allow that the matter exuded as a consequence of inflammation of the cellular tissue, could pass by exosmose or by capillary attraction into the channel of the vessel.

After the preceding remarks, it is impossible, our Author observes, to consider phlebitis as an inflammation of the internal coat of the veins, accompanied by exudation into the interior of the vessel, and, finally, as a poisoned condition of the blood. But, this negation is insufficient: as the inquiry is to determine how these changes, which are effected in the venous blood arise, and the relations which subsist between them, and the changes in the coats of the veins. We are impelled to admit a primary condition of the blood—a peculiar diathesis, and to hold the phlebitis as altogether secondary. Rokitansky is of this opinion, and many of the French school. Doctor Meinel, however, goes further; he even denies this distinction of the celebrated pathologist of Vienna, believing that the false membranes, the fibrinous concretions, and the pus met with in the veins proceed directly from the blood. The production of false membranes, for instance, is explained satisfactorily enough, they are immediate metamorphoses of the fibrine; and are effected in the same way as obliteration of an artery. It is also according to the same laws that the fibrous laminæ are produced, which are discovered between the two layers of the arachnoid in cases of intrameningeal apoplexy.

In all the cases there is no occasion whatever to admit the intervention of the walls of a cavity in which these deposits may be formed.

One of the facts which more especially lead to the adoption of the term phlebitis, in the legitimate sense of the term, is the existence of pus in the vessels. It has been long a prevalent opinion (in which many individuals at present concur) that the appearance of pus necessarily establishes the existence of previous inflammation. But this inflammation does not take place, and yet the presence of the pus is indisputed. The pus cannot be derived from without; in several of the illustrations given by the authors, the veins opened into a purulent deposit, and still the vessel was full of blood. Again, it cannot be conceived that the pus, with its large globules, has permeated the walls of the vascular membranes. Dr. Meinel, confining himself to the determination of the anatomical fact, shows that the fibrine of a clot, within a vessel, is converted into pus, under certain conditions, and in a specified time. The first of these propositions was ascertained by Vogel, who opposed the views of Donné and Gendrin, that the blood corpuscles themselves were transformed into purulent globules. Gluge and Rokitansky followed Vogel, and referred to a particular kind of fibrine, named *croupal*, this disposition to pass into pus. By the use of the microscope, Kœslin and Nasse have given further proof of the fact.

The decomposition, or rather the solution of the fibrine, precedes the production of the pus; it passes into a matter highly granular, amorphous, containing masses of varying size. This is the incipient stage of the production of the pus; the solution of the fibrine being a preparatory step to the generation of pus.

The subsequent facts which appear to bear upon the question are these:—

1. The absence of the phenomena of inflammation.

2. The fact, that almost invariably the softening

which precedes the solution of the fibrine commences in the centre of the coagulum.

3. The appearance of pus in the middle of the fibrinous clots found in the pulmonic heart, without any purulent production in the rest of the body.

A remarkable case is given by the author of these fibrinous concretions of the heart, discovered in a female after phthisis. Both ventricles were full of coagulated black blood. After removing these clots, there were found, only however in the right ventricle, white clots composed of pure fibrin, but not in any way adherent to the substance of that organ. They were soft in the middle, and formed of a finely granular amorphous matter, containing much fat, fatty globules free or conglomerated, a mass of rounded granules, and pale round cells, of the size of pus globules, but having only one nucleus.

In the further explanation of the changes undergone by the cellular coat, our author remarks that the functional disturbance which that membrane suffers is the chief cause of the change of its structure. The explanation will be readily understood, if it be admitted with Naumann, that inflammation is "the sudden check of the normal nutritive process." As to the cause which excites this functional disturbance, we must look for it in the coagulum within the vessel.

The chief results of the author are embraced in the four following propositions:—

1. The internal membrane of the vessels is not susceptible of inflammation; it is destitute of blood vessels; as an elementary tissue of a very low degree of organisation, it is liable to other laws of the nutritive process.

2. Wounds of the veins heal independently of the internal and middle coat, by inflammation of the cellular tissue, and by the partial organization of the clot external to the vessel.

3. In the case of phlebitis, the cause which affects in so injurious a manner the current of the blood does not originate in the walls of the vessels. The clots and fibrinous concretions termed inflammatory false membranes, ought to be deemed as deposits from the fluid blood which subsequently coagulate.

4. That constitution of the blood, which, in its early stage, determines these coagulations, explains, when in its advanced state, the presence of these masses of purulent matter found within the veins, and likewise affords the *rationale* of the purulent accumulation, noticed in the most marked *pyemic* affections on the surface of serous or mucous tissues.—*Gazette Medicale.*

ON THE CHANGES WHICH THE BLOOD UNDERGOES IN CONSEQUENCE OF EXTERNAL INJURIES.

By Dr. ZIMMERMAN.

The matter discussed in this paper, is for the most part novel. The observations of Andral and Gavarret, with those of Popp, are all we know on this question. The experiments were made on dogs. The following were the results:—

Consequent on slight external injuries or chemical irritation of the integuments, the blood is always changed, the amount of its solid particles being diminished. In one case, for instance, 1000 grammes of blood of the jugular vein contained 198·7 of solid matters; and in 1000 grammes of serum these amounted to 88·3. Three days afterwards, the blood in the jugular vein contained 171·6, and the serum 83·6 parts. The loss of the solid particles in the serum was not in the same proportion as in the solid matter of the blood. The decrease was chiefly in the globules, the ratio of which, prior to the experiment, was 119,037, but only 93·150 after. The amount of fibrine had increased—being, before the trial, 2·069; and after, 2·350. After wounds the quantity of fibrine always increases, but it diminishes some time afterwards.

Further, the blood is not merely modified as to the quantity of its constituent particles; but its character is changed. Hence the colouring particles show a greater disposition to attract each other. The colourless particles also attract each other, and agglutinate; and the young cells, not yet developed, exhibit the same attractive force. As regards the fibrine, it coagulates more slowly. If in consequence of a wound, suppuration ensues, and the animal suffers from a purulent and bloody discharge, attended with fever, the amount of fibrine is still more increased, (3·580 fibrine, 70·500 serum, 14·820 blood corpuscles,) and the fibrine in that case coagulates slowly. The serum presents a striking appearance; at first clear, it becomes suddenly clouded by the production of a great number of fatty particles.

THE PANCREAS OF FISHES.

Until lately a glandular pancreas has not been found in those fishes which possess appendices pyloricæ, whence these latter structures have been regarded as their equivalents.

This was universally believed until Alessandrini found both existing together in the Sturgeon.

Muller announced the presence of a glandular pancreas in the Lota, but afterwards retracted the statement.

More recently Wagner stated, that in the Trout a glandular pancreas co-existed with numerous pyloric appendices. But no other details (as to its duct, &c.) having been given, the statement remained unnoticed.

Without knowing of this, in March, 1846, the Author discovered a glandular pancreas in the Salmon and Turbot. He announced his discovery orally to Muller and Schultz, the former of whom had recently been able to confirm the truth of Alessandrini's statement. On continuing his observations, the Author was able to verify a glandular pancreas in many of the native fishes provided with pyloric appendices. The details of these observations are contained in an Inaugural Dissertation by Dr. Brockmann, "De pancreate piscium." The following are the general results:—

1. A glandular pancreas exists in Salmo Salar (the Salmon), Clupea Harengus (the Herring), Gadus Callarias, Cottus Scorpius, Perca-Fluviatilis (the Perch), Pleuronectes Platessa and Maximus, Belone Longirostis, and Cyprinus Brama (the Bream). Some of these have the appendices; in others, as Pleuronectus, they are abortive; finally, in Belone and Cyprinus they are altogether wanting.

2. The pancreas of the Salmon is broad, thin, and composed of numerous lobes; it is solid, small, and compact in the Sturgeon, the Perch, and the Sole. In the Belone it is broken up like a bunch of grapes, the stalks of which would represent the numerous efferent ducts.

3. In the Sturgeon, Perch, Bream, and Pleuronectes maximus, the short pancreatic duct enters the duodenum close to, but separate from, the bile duct. In the Salmon and Pleuronectes platessa, it is longer, and apparently united with the bile duct; but more exact observation shows the latter apparently single duct to be composed of two tubes, the bile and pancreatic duct, closely united to each other. In the belone, the two ducts really unite, and open into the duodenum by a common aperture.—*Professor Stannius in Muller's Archiv.*, p. 405.

QUARREL IN THE FRENCH ACADEMY.

Rather a fierce quarrel has arisen in the Parisian Academy of Medicine, between M. Levy, the author of a clinical and statistical work on Cerebro-spinal Meningitis, and M. Gaultier de Claubry, one of the Commission, to whom the work was entrusted. On the 3rd of October, M. Gaultier de Claubry read a long Report, stating, that M. Levy's work was deserving of commendation, but was not founded on sufficiently minute observations. M. Levy has indignantly protested against this opinion, and Begin and Piorry who were the other members of the Commission, declared that M. Gaultier de Claubry had never consulted them in drawing up his Report, and that they disowned it. Thereupon ensued a very pretty quarrel. We shall give a short analysis of M. Levy's paper in our next Number.—(*Gaz. Med.* Oct. 20, and *L'Union Med.* Oct. 18.)

ABSORPTION OF EFFUSED SEROUS FLUIDS DURING CHOLERA.

At a late meeting of the Société Medicale des Hopitaux de Paris, numerous cases were given in which the effused fluids of ascites, pleurisy, and anasarca had disappeared rapidly during an attack of cholera; in one case mentioned by M. Gillette, ascites, consequent on liver and heart disease, disappeared during cholera, and re-appeared after convalescence. M. Gendrin published a case of this kind in 1832. In this country the fact of absorption of dropsical fluids has been noticed, and would seem to imply that absorption is not so rapidly diminished, except in so far as the intestinal mucous surface is concerned, as has been supposed. M. Hourteloup has observed, that encysted dropsy of the ovary is not thus dissipated.—*L'Union Medicale.*

RESOLUTION OF INFLAMMATIONS DURING CHOLERA.

A case in which pneumonia appears to have been cut short by cholera, has been given by M. Tardieu. M. Bouvoir has related a case in which the symptoms were only suspended, and returned when the cholera had ceased. The expectoration was at once suppressed. M. Valleix has seen pneumonic patients attacked by cholera. There was no rapid abatement of the pneumonia, but gradual improvement after three or four days. In two cases which occurred to M. Gillette, the pneumonia seemed totally unaffected by the cholera.—*L'Union Med.*

DEATH FROM CHLOROFORM.

Another death from chloroform has lately occurred in Paris, and has been reported by M. de Confevron. The patient, a woman of 33 years, who had been some time before etherised without ill effects, inhaled chloroform previous to the extraction of a tooth. The chloroform was given very carefully and slowly. After insensibility had been apparently produced, the operator was about to commence, when the patient perceiving herself not sufficiently affected repulsed his hand and made signs for more chloroform. She pressed the handkerchief to her mouth, and made four or five deep inspirations. Almost immediately the face became pale, the face contracted, the pupils horribly dilated, the teeth clenched, and the head thrown back. Ammonia, galvanism, artificial respiration, and other means did not restore her. On *post-mortem* examination no structural disease was discovered; the cerebral vessels were congested; in all the larger veins at the base of the cranium there were many bubbles of air. The left auricle of the heart contained black fluid, in which also were air bubbles. The large veins contained black fluid blood. M. Confevron refers the bubbles of air to the strong insufflations he practised; he considered the death to have resulted from the directly noxious influence of the chloroform upon the nervous system.—*Gazette Medicale*, Oct. 20.

MUSCLES IN THE SIGMOID VALVES.

M. Monneret has described the muscular fibres seated in the sigmoid valves of the aorta and pulmonary artery rather differently from most writers. He makes two sets, antagonistic of each other. One muscle, visible to the naked eye, passes from the superior angle of the valvule, and descends to interlace with the fibres coming from the other side. The function of this muscle is to raise the valvule. The other muscle runs from the free to the attached border of the valvule; the fibres are very fine, and behind the corpus aurantii very numerous. Its function is to depress the valvule. The fibres of both are pale and unstriped.

M. Majendie denies these functions to the muscular fibres, and contends that the valves are raised and depressed solely by the mechanical force of the blood. M. Monneret has deduced the functions of the glands merely from their apparent course and attachments.—*Gaz. Med.* Oct. 20.

SUGAR IN CHOLERA PERSPIRATION.

M. Pousson has, like M. Doyere, found sugar in the sweat of an old woman dying of cholera. It was easily detected by the copper test. It appears however that the sweat was taken from the face, and that the patient had been drinking sugared liquids, so that there may have been a fallacy.—*L'Union Medicale*, Oct. 18.

RESPIRATION AND ANIMAL HEAT IN CHOLERA.

M. Doyere has recently presented some observ-

ations on the above subject to the Academy of Sciences. They are the result of more than 300 analyses of the air expired by cholera patients. The author remarks, that if we consider the relation between the development of animal heat and the composition of the expired air, we must distinguish two well marked periods in Asiatic cholera. In the first period these two classes of phenomena bear a direct relation to each other: in the second period, this relation becomes inverse.

The first period is the cold stage, when it leads speedily to death, or to rapid convalescence. During this stage, the proportion of carbonic acid contained in the expired air constantly falls, and sometimes in a very remarkable degree; but the fall is not uniform: it undergoes many oscillations. The limits of the diminution are between 10 and 20 per cent. of the normal quantity. The cases appeared to be more dangerous, and death imminent, in proportion to the low degree of carbonic acid in the air of expiration. Thus, in one case, which terminated most rapidly, the carbonic acid was reduced to a three-thousandth (3·1000) part. The second period, according to M. Doyere, is that which precedes death by one or two hours; in fact, it is the agony. Here the proportions of carbonic gas expired, and of animal heat developed, are in inverse ratio to each other. The absolute quantity of the gas falls as before, but the animal caloric rises in a most striking degree up to the very moment of death The rise of animal heat may be general, or confined to some internal region; or to an external region, such as the axilla, back, &c. Generally it does not exceed 1° or 2° Cent.; but, in one case the author noticed a development of animal heat from 37° to 42°.

In another case, that of a woman whose body had been exposed in the dead-house for six hours, without any other covering than a sheet, the heat of the interior of the pelvis was 41·7°, while the skin of the chest gave a heat of only 33·4°. Five hours previously to the death, the heat of the axilla was 37·2°, while under the masseter it was 29·4°. The heat of the room was about 23° or 24°.

The above observations are calculated to explain the popular belief relative to the body becoming hot after death *from cholera*. The author does not think that this ever occurs; but that the animal heat becomes displaced from one part of the body to another, and thus gives rise to the error. In all the cases which he examined, the rise of temperature, when once begun, continued up to the moment of death; the heat then remained stationary for fifteen or thirty minutes, after which it fell. The most careful analysis of the expired air did not lead to the discovery of any other change than that in the proportion of carbonic acid now indicated.

Death of Edgar Poe.—The papers announce the decease of Edgar Poe, at Baltimore, United States, on the 7th of last month. Mr. Poe was known in America as an author and a poet; the Medical Profession in this country are more acquainted with his reputation as a mesmeriser. A strange pamphlet written by him was republished in this country a few years ago, in which he detailed the results (?) of his mesmeric experiments on a dying friend. He stated that, having been long desirous to ascertain the effects that would be produced by such a proceeding, he applied to a strong-minded friend, who was dying from consumption, and obtained his consent to the experiment being practised on him. Having ascertained from his medical attendant that death would occur in the course of an hour or two, he began the mesmerising process, and succeeded in producing the mesmeric condition. While in this state death is said actually to have occurred, and to have been announced by the corpse himself. The process of putrefaction was kept at bay, according to Mr. Poe, by the mesmerising agency, and the body remained fresh and undecomposed for a lengthened period of time—we believe about a year; but not having the pamphlet at hand, we are not certain. The demesmerising process was then commenced, and carried through; on the completion of the last pass, the body be- [illegible]

credit can be given to the statements it contains.

Complaints having reached us of the irregular delivery of the Medical Times *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the Medical Times, *147, Strand."*

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, Wm. S. Orr and Co.

THE MEDICAL TIMES.

SATURDAY, NOVEMBER 10, 1849.

Some future Macaulay, two centuries hence, may possibly attempt to trace out the impression which the gradual progress of commerce and manufactures has made on the social condition of our poor. The attempt would be easy now to us, under whose eyes the system has been developed; it will be almost impossible to the Macaulay of the 21st century, who can but excavate half-obliterated images from the buried monuments of former eras, and, with delicate but erring chisel, retrace the faded lineaments. But, if he be able to attain to anything like real knowledge on this subject, he may sum up the results of this investigation somewhat as follows:—

"In the year 1848 the unprecedented commercial activity of the preceding century had borne its fruits. The age of great cities had commenced. London, Manchester, Liverpool, and Glasgow had shot up like Jonah's gourd. In the morning, it was a seed placed in fertile earth; in the evening, a large tree in which the fowls of the air roosted. The wealth of these cities astonished the world. The people symbolized the abundance of riches by saying that the streets were paved with gold. The desire for wealth grew with the wealth itself. Unbounded efforts were made to add to the already fabulous store. Trade and manufactures were carried on with an energy unknown in the annals of mankind. The goods of England glutted the markets of the world. England was the gigantic money-lender to whom all nations were the bounden debtors. Yet, in the midst of all this wealth, there were signs which made men pause and tremble. From time to time, murmurs as of earthquakes rose from beneath this mighty structure, built so royally, and startled the dwellers in the upper air. The music of the feast was sometimes harshly mingled with the groans of distress and the curses of want. For, while the tree spread its stately branches to the sky, there was rottenness at its roots. The bulk of the people were no partakers in the national grandeur. The hovels of the poor formed a strange contrast to the palaces of the aristocracy, and the mansions of the middle class. The taxes of Government had enforced a rigid economy of light; the landlord had been equally penurious of his space; the great Water Companies neglected the districts from whose miserable inhabitants they could gain no profit. No sufficient means were taken to remove from the dwellings of the poor the refuse and offal, which are the breeders of pestilence. The dead, barely covered by decent earth, corrupted in the midst of the living. No superintendence was exerted over the retail dealers of food to the lower class. These men, as formerly, pursued their nefarious trade, and the poor, as formerly, suffered from their adulteration. Government dreaded to impede trade by legislating for manufactures, so, except in a few flagrant instances, the factories poured their refuse into rivers and sewers, and their smoke into Heaven's atmosphere. No care was taken to remove the unhealthy influences of unhealthy trades; therefore, in some towns, the average duration of life was fearfully reduced. The mortality of these large cities rose surprisingly over that of the open country. If an artisan left his native town to live in London, he gave up the chances of several years of life. The amount of sickness, entailing destitution and poverty, was immense. Thence ensued an enormous Poor-rate, which pressed heavily on the smaller shopkeepers. In some towns there occurred a frightful number of deaths among infants, and, on inquiry, it was found possible to refer this mortality only to the unhealthy influences to which these children were subjected, or to the prevalence of a fearful crime which human nature shrunk from contemplating. In the midst of all this, a wide-spread famine in Ireland hurled into the English towns the most improvident and careless class of Irishmen. In every large town, in Glasgow, in Liverpool, in London, the Celts crowded together and formed an Irish quarter. They brought into their new homes the recklessness, filth, and misery of their fatherland. They made the dirty and wretched inhabitants among whom they crowded, appear, by contrast, clean and comfortable. Beneath the lowest deep they disclosed a lower still. Their diseases followed them, and the spotted typhus tracked their footsteps like a gloomy shadow. At length the magnitude of the evil aroused inquiry. Earnest and powerful men laid bare the secrets of these lower grades of social life, and urged upon the Government the necessity of reform. In the midst of these entreaties, it began to be rumoured that that terrible sickness, than which none with more appalling features had ever afflicted humanity, had again commenced to pass from its Oriental birth-place towards our northern and colder climes. The approach of the Cholera, in fact, swept away the scruples of statesmen and the opposition of interested partizans. The Government determined to grapple with the grave circumstances of the case, and in 1848, that which was destined to be the great social revolution commenced—the Board of Health was constituted."

Such, possibly, may be the facts of the picture which the historian two centuries hence may, in language infinitely finer than our rude words, place before his contemporaries. And now, accepting these facts as true and un-

exaggerated,—and that they are so, is but too well known to those who have penetrated into the vile purlieus of this, or other cities,—let us return to the present time, and observe the measures by which the condition of our poor is attempted to be improved.

In 1848 the Public Health Act received the Royal Assent. The Government, in framing it, had met with extreme opposition from many parties who fancied that their interests might be affected, and from many individuals who, in their ease and luxury, refused to acknowledge as possible the frightful reports which were laid before them. Fearful of failing altogether, the Government, as usual, resorted to compromise, and a mutilated Health Act was placed on the statute-book.

Without entering into the details of this Act, suffice it to say that it is ineffective. The only part which is at present worked out, is that which relates to the making of sewers. It appears, indeed, as if everything else had been sacrificed to this; so imperfectly are the clauses worded respecting water supply, intramural burials, regulations of public buildings and lodging-houses, superintendence of factories, and trades. The great subject of adulterations of food is almost passed over—a single clause providing that bad meat shall not be sold. As might have been expected, since the passing of the Act, its incapability of dealing with the great questions at issue has been abundantly proved, and amendments which have been made in it have left it little better than before.

One compromise which was resorted to is so characteristic that we must refer to it. Instead of applying the Act to the whole kingdom, without reserve, the Government yielded to the opposition of the local authorities, and the Bill, as it passed the House of Commons, was to apply only to the towns which might, of their own accord, petition to be purified. Subsequently, in the House of Lords, a clause was introduced, we believe, by the Bishop of London, by which it was provided, that if the mortality of any town should exceed the proportion of 23 to 1000, such town should come under the operation of the Act. Now, inasmuch as the very principle of this clause was based on the supposition, that the improvements contemplated by the Act would reduce the mortality below 23 per 1000, the proposal to allow the mortality to reach 23 per 1000, was an absolute throwing away of mens' life. The parties who opposed the Bill were so far justified in their opposition, because they believed, or, at least, it is to be presumed they believed, that the Act would not produce the benefits its advocates contended. But that the sanitary Reformers, who affirmed that they could, even in the large cities, reduce the mortality to 20 per 1000, should have consented to this arrangement, is actually no better than being accessory to murder. They should have rejected the Bill altogether, rather than have admitted such a clause.

In the matter of sewers only did the Act appear to be efficient; and, even here, the mechanism was as clumsy as could be. The Act was empowered to make sewers in towns which petitioned, or whose mortality was more than 23 per 1000, except in the case of the City of London, the Metropolitan Commissioners of Sewers, and the Commissioners of the Sewers of the Regent's Park. Therefore, while all the rest of England was committed to the General Board of Health, the principal city which required more sewerage than any other, and which under the old system had been worse sewered than any, was exempted from the control of the Health Act. To lessen this difficulty as much as possible, the Metropolitan Commission of Sewers was re-organised, and the Members of the Board of Health (nominated by the new Act) were made the prominent members of a new Commission. By this compromise a certain amount of uniformity was apparently gained. The Board of Health, who superintended the sewers of York, of Leeds, or of Manchester, would also, as being Metropolitan Commissioners of Sewers, superintend a great part of the sewers of London. But unfortunately, from causes into which we shall enter at another time, the new Metropolitan Commission of Sewers came to an untimely end, and, when the Government reconstituted it a few weeks back, the Members of the Board of Health were excluded. The Board of Health then discovered very sufficient reasons why they should be altogether separate from the Commissioners of Sewers; although it may be observed that the same reasons were operative a year ago in respect of the metropolitan sewers, and are operative now in respect of all the other towns whose sewerage is, or is to be, under their superintendence.

But at the present moment, the original discrepancies are in full force. One set of people are to make sewers for the City of London; another for London without the City; a third for the Regent's Park; a fourth for some other parts of England; and Scotland and Ireland are presumed to do well enough without any sewers at all. From this system nothing but confusion worse confounded can be expected; and the only thing we can pray for is, that no unlucky and unusual desire to do their duty, may stimulate the several Commissioners of Sewers to any activity until the whole matter can be again fairly considered by the Legislature, and, if possible, a wise and comprehensive scheme be devised.

In reflecting upon this subject, it is apparent that the present failure of the Health Act is owing to two capital errors. In the first place, the thing admitted of no compromise. If the great principles of Sanitary Reform are true, everything must give way to them. There is no necessity that vested interests should be needlessly sacrificed, or that more changes should be introduced than are necessary; but still nothing should stand in the way of the rule, that where the interests of Landlords, of Corporations, of Water Companies, or of other parties, are opposed to, and are subversive of, the health of the people, those interests must be surrendered as being unjust, and pernicious to the public weal. It may be said, that the advent of the Cholera drove the Government to this Bill; and this may be admitted as an argument for them; although, be it remembered, that the Board of Health have, almost literally, been enabled to oppose no bar to the disease. For this we do not blame them; it was beyond their power, but it is ample proof that, after all, the compromise profited little.

The second capital error was in the choice of the men to administer the Health Act. Without disparaging, in the remotest degree, the present Members of the Board of Health, we must again express the opinion we have before avowed, that the Medical Profession, and of that Profession its most worthy members, are the only persons who can grasp the subject in all its width, assign to each condition its proper importance, and proceed, with the aid of the highest science, to the determination of the scheme which is to affect so deeply the social condition of this people.

Into the nature of this scheme we shall enter in an early Number. We may so far anticipate it as to state that the plans which have been hitherto devised, or in part acted upon by the Board of Health, have evidently originated from men who, whatever their abilities, are biassed in one particular direction. But partial measures to remedy the giant evils under which we labour can only be compared to those mounds of sand which children heap up on the shore to bar the progress of the sea.

THE CORONER FOR MIDDLESEX AND THE INQUEST ON MR. MORTON.

We announced last week the sudden and unexpected death of Mr. Morton, of University College. Since our paragraph was written, the disclosures of the Coroner's inquest have rendered more painful still, this painful subject. We cannot avoid lamenting, that the detail of the causes which led to this terrible suicide was permitted to find its way into the daily Press. The ends of justice did not demand, that the secret failings of this unfortunate gentleman, if he had any, should be made the subject of vulgar comment; that the confessions of a debasing vice which, acting on a temperament originally susceptible, impaired and perverted the faculties of so fine a mind, should be chronicled for the pleasure of scandal-mongers, and paraded before the world for the edification of its gossips. A single good result, may, however, arise from the publicity which has been given to the transaction. Should the implied charge be true, and the strongest ground for admitting the belief that it might have been so, is found in the declaration of the very man who heard the depositions,—that the unfortunate gentleman was the subject of *delirium tremens*,—we can then have no difficulty in conceiving what may have been the grounds on which the Council of University College refused on a recent occasion to promote this unfortunate gentleman. It is evident that the Council may have been but too well justified in the course they adopted; and when we remember the attacks to which, in consequence, some members of the College were exposed, we cannot speak too highly of the gentlemanly feeling and friendly forbearance, which would not permit the sacrifice of the reputation of a colleague by making known the real grounds on which they acted.

We should not have recurred to an event so little attractive to us, either as Journalists or as Medical men, had there not appeared, last week, a statement on this sub-

ject, in the pages of a Medical Journal supposed to be under the management of the very Coroner before whom the inquest on Mr. Morton's body was held, and by whom, therefore, those affecting and melancholy documents, which testified to the real cause of this frightful event, had been officially examined. When, after reading this Article, in which Mr. Morton's death, as well as the deaths of Potter, Liston, Thomson, and Cooper, were attributed "to the blighting influences of the atmosphere of University College," we turned to the columns of the daily *Times*, and found it there reported, as a remark of the Coroner, that the evidence before the jury "showed that a very small quantity of any spirituous liquor would produce these distressing symptoms in the morning—symptoms which, in fact, were those of *delirium tremens*,"—we had some difficulty in persuading ourselves, that the leading Article alluded to and the Coroner's Report, as given in the *Times*, referred to the same person. But when it became clear that they *did* refer to the same person; when we were satisfied that in a paper presumed to be under the direction of the Coroner, a statement had been inserted, to which the report of the Coroner's own proceedings in the Daily papers gave a direct denial, we did not know which most to wonder at, the bitter hostility which makes University College ever the target for its shot, or the ridiculous oversight which permitted the issue of an assertion to which the proceedings before the Coroner himself furnished a damning contradiction.

And when we reflected that Potter died from a dissecting wound, Liston of aneurism of the aorta, Thomson of a chest disease, and Cooper of gout and general decay, we were inclined to marvel at the variable effects of this "blighting atmosphere," which can kill in so many ways. Let us recommend the *ingenious* writer of the Article,—which we will not insult the Coroner by attributing to his really able pen,—to reflect whether this same "blighting atmosphere," which he has evidently inhaled in its proper locality, may not have exerted its baneful influence even upon *himself*. Possibly, as it has so many modes of action, it may not limit its effects to the physical health; perhaps, it may touch the moral. If a little obliquity, a little difficulty of distinguishing between right and wrong, truth and falsehood, have been thus produced, it would account to us for the very peculiar view which the Writer takes of the share which University College had in Mr. Morton's death. We should like to investigate this curious point, and may possibly recur to it more in detail on another occasion.

But to return, from the subordinate to the Coroner. We cannot hesitate to condemn in the strongest terms the conduct of this individual. Holding an office of no mean importance,—being called upon to exercise, if any man is, qualities of candour and truthfulness in those difficult investigations which fall under the jurisdiction of the Coroner, it would seem that he has yet penned, or permitted to be penned, and to be published in the paper under his control, a statement which, in effect, gives a false account of an investigation which he himself conducted.

We have another word to say in our capacity as Journalists. When Milton composed his magnificent "speech for the liberty of unlicensed printing," he did not overlook the fact, that men would arise who would use basely the liberty for which he prayed, and would turn the beneficent instrument of progress and civilisation into a weapon by the which they might hurl upon their nobler opponents the vile slander which *could* not be cast back. But Milton believed, and justly, that the licentious slanderer, and, as he termed it, the "lurking railer," would be held in check by the firm determination of honest and honourable men, to permit no unlawful tampering with the mighty instrument he sought to free from the shackles of authority and restriction.

And this is, indeed, the case. Sooner or later the censure of his fellow-men will light on him who uses, for unworthy purposes, the power which has been given for the common benefit of all. Sooner or later, the unjust writer, who attacks his enemy from under the secret covert of a public journal, will be detected and exposed. We will warn Mr. Wakley, that he has not been sufficiently careful in the selection he has made of the individuals who address the public through his pages, and we foresee, that unless he speedily exert a more careful superintendence, few men will care even to acknowledge to others, that they are readers of the *Lancet*.

THE CHOLERA REPORT OF THE COLLEGE OF PHYSICIANS.

On a more attentive consideration of the Cholera Report of the College of Physicians, we do not hesitate in expressing our opinion, that the fungous theory of Cholera, as developed by Dr. Budd, is set at rest for ever. Our readers will remember that the following points were essential to the very foundation of this theory; viz., that the so-called cholera fungi should be present in all cholera discharges and cholera atmospheres, and should be absent in all other cases. Now, the numerous experiments of Drs. Baly and Gull prove satisfactorily that these bodies are not always to be found in cholera atmospheres, and that they are no essential part of cholera dejections. And in this latter case, the evidence of two such experienced microscopists, to say nothing of Mr. Busk, Dr. Parker of the London Hospital, Dr. Bennett, and Dr. Robertson of Edinburgh, and others, is not only negative, but positive evidence, that the "cholera cells" did not exist in the cases examined. If we reject all the other observations, these decide the case. The cholera cells must be incidental only, not necessary and indispensable. But to back this evidence we have the observations of Drs. Jenner and Baly on the typhoid stools, showing that the cholera "fungi" are not peculiar to cholera. There cannot, therefore, be a doubt on the subject; and as the Bristol observers have not, for the most part, been guilty of false philosophy, since they only chronicled what they saw, and did not draw the extravagant inferences from their experiments in which some of their friends indulged, we trust there will be no difficulty in considering the question closed.

But another point remains behind, of considerable interest. It seems settled, that annular bodies, of peculiar form, exist often in both cholera and typhoid stools, although they are frequently absent from the former, and probably also may be from the latter. Now, what is their nature? whence are they derived? what do they signify? These inquiries are not, we think, satisfactorily settled by the College of Physicians, and, indeed, it was not their object to go into them; but they are well worthy of consideration; and, if the Bristol observers will diligently attempt the solution of the problem, the temporary error into which they, or rather their friends, have fallen, they may still bring forth fruits of no mean importance to science.

We cannot avoid again congratulating the College of Physicians on the zeal and ability which their Committee have shown in this matter. In common with the great body of General Practitioners, whose organ we are, we are happy to see useful and valuable results proceeding from a body who have it in their power to do so much to promote the advancement of Medical knowledge. The College, at the present moment, is in a position, if it proceed on *wise* and *liberal* principles, to place itself in its proper place, at the head of the Profession, and to lead the van of Science. Let it be just to all grades of the Profession of which it is a part, and we will cheerfully accord it our best assistance.

ROYAL COLLEGE OF SURGEONS.

We are enabled to state, that the Council of the Royal College of Surgeons of England, on Thursday night, determined to apply to the Secretary of State for power to grant relief to members of the College, of twenty years' standing, desirous of being admitted to the Fellowship.

At the present moment we can do little more than congratulate our brethren of the College of Surgeons, on this the first step taken to neutralize the injurious tendency of the Charter of 1843. But the date of membership is too far back. In common justice, all members before 1843 should be admissible to the Fellowship, and those who passed the College examination subsequently to the granting of the new Charter should become Fellows only on the Fellowship examination, or by a seniority of twenty years' membership and the requisite testimonials. *Le bon temps viendra.*

DRAINAGE.

While the state of the public health has been duly chronicled in the columns of the *Medical Times*, our readers will do us the justice to recollect, that we have not only been zealous in the cause during periods of epidemics, but we have never lost an opportunity of advocating all such measures as seemed likely to promote sanitary improvement of a permanent kind. Now that the cholera has left us, we hasten to turn our thoughts towards the best means of preventing its recurrence, and at the same time to develope a progressive system of extensive improvement as respects the cleanliness of our abodes, and the salubrity of the air we breathe when abroad in the streets.

With this view we propose to give a series of

articles on DRAINAGE, which shall imbody practical outline of the whole of this subject, and comprise a summary of its many important bearings upon the health, wealth, and morality of society.

PAYMENT OF MEDICAL REFEREES BY ASSURANCE COMPANIES.

We have more than once alluded to this subject. It is one which should never have needed discussion. The payment of Medical Men by Insurance Companies should be the rule, and not the exception, as we regret to say it is. The principle of equitable remuneration is, however, gaining ground, and those offices who resist it must do so to their own loss and discredit. It requires only the reasoning of common sense to see that the most valuable information, as well as the best safeguard, are given to the Company by the confidential report of the private medical attendant of the proposed life, and such information ought not to be afforded without adequate professional remuneration. We are led to notice the Prospectus of a new and apparently highly respectable Office, because we see that the Directors have resolved to pay the usual *honorarium* for inquiries, without respect to the result. The London Mutual Life and Guarantee Society has adopted a course which reflects credit upon its projectors; for what can be more absurd than to refuse to pay for information which shall induce them to reject a life. If any information is important, surely that is, which leads to such a result; for the only value in the Report, is to ascertain from the regular Medical Adviser the real physical condition of the proposed life.

THE OPERATIVE SURGERY OF JOHANN FRIEDRICH DIEFFENBACH.

Edited by

ALEXANDER URE, Esq.,

Fellow of the College of Surgeons of England, and Surgeon to the Westminster General Dispensary, &c.

(Continued from page 339.)

OF TYING THE INFERIOR THYROID ARTERY.

Rieke recommends this artery to be tied between the two slips of the mastoid muscle; and Dieterich follows nearly the same course. He makes an incision two inches and a-half long at the inner border of the clavicular portion of the mastoid muscle, beginning above the clavicle; then a second from the lower angle of the wound to the upper border of the clavicle, running outwards, an inch and a half in length. The platysma myoides, fascia, and both portions of the mastoid muscle are detached, and the clavicular slip loosed from its bony insertion, in order not to injure the phrenic nerve. In penetrating through the cellular texture, the transverse artery of the scapula is found running horizontally with the subclavian vein. The former is to be followed inwards and upwards as far as the inferior thyroid artery, and the latter tied above its origin from the subclavian.

This operation, if resorted to for the cure of bronchocele, is fraught with greater danger than the disease, inasmuch as the internal jugular vein, par vagum, great sympathetic and phrenic nerve, are all in the way. It can scarcely be undertaken, moreover, on the left side, owing to the thoracic duct. The anatomical difficulties are not evaded by adopting either of the plans proposed by Langenbeck, Colles, Sir Charles Bell, or Velpeau.

OF TYING THE INTERNAL MAMMARY ARTERY.

The tying of this artery is attended with some difficulty between the first and second ribs, from its proximity to the border of the sternum, and from the risk of lesion to the veins; lower down it is easily tied. The incision is made in the intercostal space an inch and a half long, commencing from the edge of the sternum, and from the upper border of the rib below, and winding outwards and upwards towards the under border of the rib above, without approaching too near, or implicating the intercostal artery. On reaching the aponeurosis of the greater pectoral muscle, this is to be cut across upon the subjacent muscle. Beneath are thin cellular and ligamentous texture. These, together with the internal intercostal muscle are to be separated, then the cellular envelope of the artery slit open, the artery insulated from the vein, surrounded with a thread passed by means of a small eyed-hook, and the knot made. The ligature is most easily applied in the third and fourth intercostal space, because there the artery is larger, runs about three-fourths of an inch from the sternum, and lies upon the tendinous expansion of the triangularis sterni muscle. Velpeau makes a very free incision, about three inches long, parallel with the lateral border of the sternum. Despite the length of this incision, however, there will not be room enough to penetrate into the intercostal space. Chelius, on the other hand, very judiciously exposes the artery, by an incision, beginning from the lateral margin of the sternum, and running directly in the middle of the intercostal space. I can confirm the advantages of this procedure.

OF TYING THE BRACHIAL ARTERY.

The patient lies upon the operating table, turned to the opposite side. The arm, entrusted to an assistant, is stretched out at an angle from the body, turned at the same time rather supine, because, if prone, the margin of the biceps would lap over the artery. The ligature can be applied, according to circumstances, either in the middle of the arm, or above the bend of the elbow, at the ulnar side of the biceps.

If the former situation be selected, the skin at the middle of the arm being held on the stretch, is to be incised along the ulnar margin of the biceps; the subcutaneous fat and cellular texture are then to be separated, and the fascia is to be slit upon a director. The artery lies close by the margin of the biceps, between two veins. To its outer side is the median vein, from which it is to be detached, and then tied.

Above the bend of the elbow the operation is even more facile. An incision is made over the internal condyle of the humerus, prolonged for a couple of inches, at least, along the ulnar margin of the biceps, extending to the fascia, which is also divided. The artery is then found to the outside of the median nerve, accompanied by the two veins. After being insulated, it is tied in the usual manner.

In some rare instances there is a high division of the brachial artery. The ulnar branch, under such circumstances, permeates the fascia, and lies immediately under the skin. Therefore, in tying the vessel for hæmorrhage or aneurism, it ought to be previously ascertained that no such bifurcation exists; otherwise ligation of the sound would obviously augment the flow of blood from the wounded trunk, an event which I have witnessed.

OF TYING THE ULNAR ARTERY.

This artery may be tied either at the middle of the forearm, or at the wrist. In the former case the incision is commenced upon the other side of the forearm, three finger's breadth apart from the inner condyle of the humerus, and three inches in length, descending along the inner margin of the ulna, and dividing the skin and fascia. On penetrating into the space between the muscles, leaving the palmaris muscle and the flexor sublimis to the outer side, and the flexor carpi ulnaris to the inner, the artery is found external to the nerves. At the wrist, an incision is made half an inch above the pisiform bone, along the outer margin of the tendon of the flexor carpi ulnaris, two inches long through the skin and fascia. Upon drawing the inner margin of the wound inwards, the artery is detected at the border of the tendon, and to the outer side of the nerve.

OF TYING THE RADIAL ARTERY.

The radial artery may be tied either at the elbow or wrist. In operating at the elbow, Averill makes an incision in the middle of the triangular space betwixt the two condyles of the humerus, and the extensors and flexors of the hand, which is begun a little below the joint, and carried for three inches downwards. The artery is bared after severing the fascia. Bierkowsky imagines a line drawn from the depression between the tendon of the biceps, and the supinator longus, and terminating at the wrist, upon the tendon of the radialis internus. In this line he makes an incision from an inch and a half to an inch and three quarters within the bend of the arm, two inches in length. At the wrist an incision two inches long is made over the styloid process of the radius, which, if prolonged, would bisect the interval between the two condyles of the humerus. Directly beneath the integument, at the inner side of the tendon of the supinator longus, lies the artery.

OF TYING THE ABDOMINAL AORTA.

Sir Astley Cooper performed this operation for the cure of an aneurism, situate partly above, partly below Poupart's ligament. The nutrition of the parts inferiorly is maintained, under favourable circumstances, after such an operation, by the inosculation of the mammaria interna with the epigastric, of the last lumbar arteries with the circumflex ilii, the hæmorrhoidal, and the pelvic arteries. After relaxing the abdominal muscles, Cooper made an incision three inches long into the linea alba, giving it a slight curve to avoid the umbilicus. One inch and a half was above, and the remainder below the navel, the cut being inclined towards the left side. "Having divided the linea alba," says he, "I made a small aperture into the peritoneum, and introduced my finger into the abdomen, and then, with a probe-pointed bistoury, enlarged the opening into the peritoneum to nearly the same extent as that of the external wound. Neither the omentum nor the intestines protruded; and during the progress of the operation only one small convolution projected beyond the wound." With his finger nail he scratched through the peritoneum on the left side of the aorta, and then, gently moving his finger from side to side, gradually passed it between the aorta and the spine, and again penetrated the peritoneum on the right side of the aorta. A blunt aneurismal needle was next conveyed under that vessel, and the thread tied, with the precaution of excluding the intestines from the noose. The wound was then closed by means of the quilled suture and adhesive plaster. (S. Cooper.) The patient survived forty hours. Sir Astley Cooper mentioned, that had he been called to perform the operation again, he would have cut off the two portions of the ligature close to the knot on the vessel, because the irritation of the bowels caused by them seemed a source of considerable danger. James operated after the same manner for an aneurism of the external iliac artery. The patient died in three hours. After Murray's operation the patient lived twenty-three hours. According to Murray and Langenbeck, the incision ought to commence three fingers' breadth across, above the superior spine of the ilium, opposite where the cruralartery lies on the pubes. I believe with Blasius, that the common iliac artery may be tied from below, according to Guthrie's method, without lacerating the peritoneum.

OF TYING THE INTERNAL ILIAC ARTERY.

Dr. W. Stevens tied this artery successfully for an aneurism of the gluteal artery. He made an incision, five inches long, through the abdominal walls in the direction of the epigastric artery, but half an inch to its outer side, as far as the peritoneum; he then detached it, with his finger, from the internal iliac and psoas muscles, searched for the vessel at the usual depth, and tied it half an inch below its origin. According to Hodgson, the centre of the incision ought to be opposite the superior anterior spine of the ilium, and its termination an inch and a half

above Poupart's ligament. Bujalsky makes a slant incision, beginning a finger's breadth above the anterior superior spine of the ilium, and running in the direction of Poupart's ligament. If the above incision is inadmissible, owing to the bulk and profundity of the aneurismal tumour, one may be made more outwards, above the spine and crest of the ilium.

OF TYING THE SUPERIOR GLUTEAL ARTERY.

The patient is placed on his face, with the toes turned inwards. The incision commences from the superior crest of the ilium, is carried, for the length of three inches, in the course of the fibres of the gluteus maximus, and towards the greater trochanter. After penetrating between the muscular fibres of the gluteus medius to the lower margin of the ilium the artery may be reached and tied, (Zang.) Lisars and Harrison lay down another but more difficult mode of procedure.

OF TYING THE ISCHIATIC ARTERY.

The patient is placed as in the preceding operation. The incision commenced under the posterior inferior spine of the ilium, is prolonged, for two and a half inches, in the track of the fibres of the gluteus maximus, towards the outer side of the tuberosity of the ischium. On exposing the great sacro-sciatic ligament, the surgeon discovers the ischiatic artery lying upon the lesser sciatic ligament and applies the ligature. The plan proposed by Sir C. Bell is not so convenient.

OF TYING THE PUDIC ARTERY.

The patient is laid on his face. The incision, of from two and a-half to three inches long, is made by the inner side of the ramus of the ischium, dividing the fat and gluteus maximus muscle, and terminating at a layer of fat. Hereupon the erector penis becomes visible, with the artery passing along its inner margin. The vessel is accompanied by two veins and the pudic nerve, and is parallel with the transverse artery of the perinæum. After being insulated from these, it is tied (Dieterich).

OF TYING THE EXTERNAL ILIAC ARTERY.

This operation was first performed by Abernethy, in the year 1796. An incision, about three inches in length, was made through the integuments of the abdomen, in the direction of the artery, the lower extremity terminating about half an inch above Poupart's ligament. The peritoneum was then pushed upwards and inwards with the fingers, and the artery secured. Sir A. Cooper preferred a semilunar incision, having the convexity directed downwards and outwards, through the integuments. One extremity of this incision was situate about an inch and a-half from the spine of the ilium, the other terminated a little above the inner margin of the abdominal ring. Graefe commenced his incision two inches from the spine of the ilium, and continued it to within a couple of inches of the abdominal ring. After the integuments are divided, the muscles are to be cut through until the peritoneum is reached. This latter being cautiously pushed aside, the artery will be found at the outside of the vein. The safest course is to pass round the ligature above the origin of the epigastric artery, because, if applied betwixt the latter and the arteria circumflexa ilii, there is a risk of no adequate internal coagulum being formed.

OF TYING THE FEMORAL ARTERY.

This artery may be tied high up in the thigh before it sends off the profunda femoris, or at the middle third.

In order to perform the high operation, an incision of from two to three inches is to be made midway between the anterior superior spine of the ilium and the symphisis pubis, in the direction of the artery, and which can be distinctly felt pulsating. The internal saphena vein is to be drawn aside, the cellular texture and inguinal glands detached, the superficial layer of fascia lata slit open, the sheath of the vessels opened, and the artery tied.

Various rules have been given for making the proper incision at the middle of the thigh. Hunter's plan is the most simple. He directs the cut to be made in the middle of the inner side of the thigh, by the inner margin of the sartorius muscle, to the extent of three inches. Scarpa terminated an incision of three inches long at the spot where the pulsation of the artery ceases to be felt. Rust drew a vertical line down the outstretched thigh from the horizontal ramus of the pubes, two inches remote from the symphysis. The extremity of this line falls upon the middle of the thigh. Graefe drew from the centre, betwixt the anterior superior spine of the ilium and the upper margin of the patella, a transverse line to the middle of the inner part of the thigh. The terminal point of this line indicates the middle of a longitudinal incision o three inches. Averill applies the ligature near the lower apex of the triangle, as circumscribed by Poupart's ligament, the triceps and sartorius. On division of the integument, the inner margin of the sartorius is seen; underneath is the artery. This muscle is to be drawn outwards, the cellular texture overlaying the arterial sheath detached, the latter opened, whereupon the artery is laid bare. The vessel, after having given off the profunda, sometimes divides into two trunks, which subsequently unite. The ligation of one alone is, in such a case, of no effect.

OF TYING THE POPLITEAL ARTERY.

The patient is placed upon the face. An incision of three inches is made along the posterior aspect of the thigh, and which ends betwixt the condyles of the femur. The surgeon then slits the aponeurosis, and penetrates through cellular texture and fat to the popliteus muscle, till he arrive at the artery deeply seated, covered by the vein and nerves. He draws the latter outwards, bends the knee in order to obviate tension, and ties the vessel.

OF TYING THE ANTERIOR TIBIAL ARTERY.

This operation is usually performed in the middle of the leg. The incision commenced a little below the middle of the tibia, is extended from its outer margin for three inches, somewhat obliquely outwards and upwards, between the anterior tibial and extensor longus digitorum muscles. The fascia being slit, on passing into the depth betwixt the above muscles, the artery is found lying upon the interosseous ligament.

OF TYING THE POSTERIOR TIBIAL ARTERY.

This can be done in three places. (Grossheim.) 1. High up in the leg; the incision begun below and between the condyles of the femur, is carried four inches down the calf. The surgeon, after dividing the aponeurosis and fibres of the gastrocnemius, will find the artery at the inner side of the external head of this muscle. 2. At the mid-leg; the incision commenced below the middle of the leg at the inner border of the gastrocnemius, is prolonged downwards in the direction of this muscle; then the muscle, with the upper portion of the tendo Achillis, is to be raised up, and the soleus cut across. There lies the artery. 3. At the ankle: an incision of two inches is made through the skin and aponeurosis, between the inner an le and the tendo Achillis, but rather nearer to he former. Almost directly below the malleolus is the artery. (Averill.)

OF TYING THE PERONEAL ARTERY.

For this purpose, an incision three inches long is made through the skin, somewhat below the mid-leg, parallel with the fibula, and behind its external margin. After dividing some muscular fibres, the artery is brought into view.

REVIEWS.

Traité d'Anatomie Pathologique Générale. Par J. Cruveilhier, Professeur d'Anatomie Pathologique à la Faculté de Médécin de Paris, &c. Tome Premier. A Paris chez J. B. Baillière. 1849. 8vo. Pp. 735.

A Treatise on General Pathological Anatomy. By J. Cruveilhier, Professor of Pathological Anatomy to the Faculty of Medicine. Vol. I. Paris: J. B. Baillière. 1849. 8vo. Pp. 735.

A new work by the celebrated Professor of Pathological Anatomy of the Parisian Faculty of Medicine calls for more than a passing notice.

Pathological Anatomy is to Pathology what Normal Anatomy is to Physiology: it unravels the structure of morbid organizations, the phenomena attending the vital actions of which constitute Pathology.

An examination of dead matter cannot teach, nor even explain *vital* phenomena. (a) We cannot tell *à priori* from the physical structure of any viscus what its vital action will be; we cannot tell *à priori* from the vital action of an organ what its physical organization is.(b) If, however, we trace an aberration of function to a lesion of structure, we are enabled, when that aberration again occurs, to predicate the existence of the same lesion. The more rigid the process of induction by which the one is affiliated to the other, the more certain we may feel of finding the two invariably associated. Let the abnormal vital phenomena, *i.e.*, the symptoms proper to any lesion of structure, be once fixed, and from that moment we are able to correct our diagnosis by anatomico-pathological researches. If these researches prove that two lesions, conjointly or separately, are found after any given group of symptoms, *i. e.*, morbid vital phenomena, then it bids us, by more minute clinical observation of the pathological phenomena to separate those peculiar to each. Let us illustrate our position: the structural change of the kidney termed Bright's disease, includes two or more distinct anatomico-pathological lesions, minute clinical observations, conjoined with careful examination, after death, of the diseased organs, will eventually enable us to determine what peculiar symptoms, heretofore grouped under one name, are peculiar, respectively, to each of these lesions. When thus precision is given to our ideas, when, by a certain expression, we mean *constant* symptoms connected with *constant* lesions, when by one name we mean one, and only one, thing, and when, by the *same* name, we mean absolutely the *same* thing, we shall be in a position to determine positively, by observation, the treatment, for we can then compare like with like, one set of cases, of any given disease, treated by one remedy, with another set of cases, of the same

(a) We here use the expression vital phenomena in opposition to, or as distinct from physical phenomena, the *result* of vital actions; thus, the closure of the mitral valve is, in a great measure, a physical phenomenon consequent on the vital action of contractility proper to the heart, &c. Now, it is manifest, that so far as purely physical phenomena are concerned we are enabled to offer, from dead structures, an explanation of the phenomena, healthy or diseased, manifested during life. But, even this power of explanation is *very* limited. Look at Endosmosis, subject to certain known laws, when a consequence of the physical properties of dead membrane; let the same membrane be under the influence of healthy vital actions, the laws which regulated the phenomenon in the dead membrane are no longer those in accordance with which it acts; and again let disease arise, and observation must anew determine the laws it obeys.

(b) A knowledge of the phenomena attending the healthy vital action of any structure or organ cannot enable us to determine what will be the modification in the vital phenomena consequent on its action when disease has altered its textures. All we can say, before observation, is, that a departure from the healthy action will ensue; but, how much the phenomena by which the action of the organ is *manifested* to our senses, or to those of the patient, will be modified, we cannot predicate; nay, we cannot say absolutely, if they will be modified at all. Thus, half the substance of a secreting organ may be so altered by disease as to be incapable of exercising its function; and the remaining half of the organ compensating by its increased action, no abnormal phenomena ensue—*i. e.*, so far as our senses enable us to take cognizance; and no one could *à priori* have declared that this would hold true of the kidneys, but be absolutely false with respect to the lungs. No one could have told beforehand, that it would hold true if certain lesions occurred gradually, but be false if the injury were inflicted suddenly.

disease, treated by anotherremedy, we can analyse, we can count. In this way pathological anatomy advances therapeutics, but in this way only; and is because false friends to the science have strive to assign to it higher powers, have attempted to deduce, from the appearance found after death, *à priori* modes of treatment, that "Some men have not feared to say, that Pathological Anatomy has caused the science of medicine to retrograde."

"Human Pathological Anatomy," our Author states, "may be studied from three points of view, from whence are derived three very distinct species of Pathological Anatomy:—1st. General Pathological Anatomy. 2nd. Pathological Anatomy applied *i.e.*, studies with reference to diseases properly so called, to their causes, their symptoms, their progress, their termination, and their treatment. 3rd. Topographical Pathological Anatomy; which has for its object to present a complete picture of the morbid lesions which may appear in each region of the human body, without reference to the affinities or discordances which exist between those lesions."

The first, only, is touched on in the present Volume. General Pathological Anatomy is defined to be an abstract or general consideration of morbid lesions, without regard to the diseases to which those lesions appertain; its essential object to be, the determination of morbid anatomical species, and the grouping of these, according to their analogies and their differences; and finally, the uniting these species into genera, orders, and classes. For this purpose, Pathological Anatomy avails itself, not only of the scalpel, but also of experiments on animals, and of chemical and microscopical researches.

"It is," he proceeds, "in this point of view, that pathological anatomy may be considered as a science distinct from others, having its own facts, its laws, its language, its method,—*the science of anatomical morbid species.*"

Pathological anatomy teaches us three things:—the seat, the organic nature, and the organic causes of diseases.

While considering the third head, our Author explains the meaning of the expression,—the anatomical character of a disease,—to be the constant co-existence of such or such symptomatic form of disease, and such or such organic lesion. "The question of causality," he adds, "may afterwards be considered and settled;" thus, as we have on previous occasions remarked, the anatomical character of a disease and the organic cause of the same disease are distinct things. True, in some cases the same lesion may be at once the invariable concomitant of the group of symptoms called the disease, and the cause of those same symptoms; and in such cases the anatomical character and the cause *happen* to be the same, but in other cases they certainly are very different; thus the anatomical character of the symptomatic disease, *i. e.*, defined by its symptoms alone, termed small-pox, is the peculiar pustule, and yet that pustule cannot be considered as the cause of the groupe of symptoms termed small-pox.

Speaking of the power of examinations after death to throw light on the cause of death, he asks—

"In how many, especially very acute diseases, do we not meet with lesions so slight as to be totally incapable of explaining death? What! do you believe that you have shown me the cause of death when, in a case of measles, of scarlet fever, or of small-pox which proves fatal at the period of invasion or of eruption, you have shown me an injection of such or such part of the mucous membrane of the alimentary canal or of the air passages?"

He further refers to cholera, hydrophobia, tetanus, epilepsy, and certain cases of sudden death, as affording examples in which anatomico-pathological researches throw no light on the cause of death, and adds that,—

"In this way pathological anatomy leads to vitalism, from which at first sight it appeared to remove us."

In the first part of the work fourteen propositions or axioms are laid down:—

1. The number of morbid species is limited.

2. Morbid species are identical, whatever may be their seat. The differences which result from the texture of the organs in which they are developed constitute only varieties. The characters of the morbid species are as inalienable as the characters of zoological species. On this point great emphasis is laid by M. Cruveilhier.

3. Lesions, as a rule, are common to all the tissues: special lesions are the exception. This is opposed to the pathological axiom of Bichat, "Each tissue has its proper lesions."

4. Each tissue, each organ has its own morbid *affinities*. Thus the lungs and the lymphatic ganglia have a morbid affinity for tubercle, the uterus and mammæ for fibrous tumours, &c.

5. There are a certain number of special lesions, such as those dependent on the peculiar formation, structure, or function of an organ.

6. Anatomical characters ought to be the basis for the determination of morbid species, without in any way being disturbed by the rank they hold in the nosological catalogue.

7. The anatomical characters are displayed in the external conformation and in the texture of the diseased organs.

8. The study of the evolution of morbid lesions is necessary for the determination of the species.

9. Experimental pathological anatomy is one of the most fertile bases of pathological anatomy, and, consequently, of pathology.

10. Compound morbid species result from the association of a certain number of lesions, and this association occurs according to certain rules, which we call *the laws of morbid association*. Among associated lesions we must distinguish coincident, consecutive, and subordinate lesions.

11. Distinct morbid species are never transformed into each other. The importance of this proposition cannot be too highly estimated. It is in direct opposition to the generally received opinion, according to which so many morbid lesions may degenerate into cancer.

"It results from innumerable observations, that a cancer is a cancer from the first moment of its formation, that fibrous tumours are fibrous from the instant of their appearance, and will continue so thirty, forty years after. The terror that the possibility of other morbid lesions degenerating into cancer inspires, is imaginary. Surgeons ought no longer to permit the idea, that a tumour of doubtful nature may eventually become cancerous, to influence their judgment in determining the propriety of extirpating it. I know no fact which unequivocally proves that a morbid tissue, the result of acute or chronic inflammation, may become cancerous." Morbid species are no more able to be transformed into each other, than are the vegetable or animal species."

12. One species of morbid lesion may be regarded as in some measure conferring an immunity against other species of lesions. Thus, fibrous tumours of the uterus afford, in some measure, an immunity against cancer of that organ. However, the immunity enjoyed is confined *absolutely* to the fibrous tumours themselves. Thus, the whole uterus may become cancerous, the fibrous tumours themselves with which it is studded only escaping.

13. Living tissues are in themselves unalterable. Other morbid lesions, which are the most essentially disorganizing—the inflammatory, tuberculous, and cancerous—are due to the infiltration of the tissues by heterogeneous matters; the tissues which appear degenerated are nothing more than tissues, the fibres of which are separated, and more or less atrophied, or hypertrophied.

14. The immediate seat of all nutrition and of all morbid secretion is the capillary system.

Without entering into the absolute truth of all these propositions, some of which would require modification before we could admit them in the abstract, we may remark, that the 2nd, 3rd, 4th, 6th, 8th, 11th, and 13th, are of extreme importance, as forming the very basis of the science of Pathological Anatomy.

Abandoning the classification of morbid lesions he before proposed, M. Cruveilhier now adopts the following:—

Order	Class		Lesions
Order 1.	1st class	..	Solutions of continuity.
	2nd	..	Adhesions.
Order 2.	3rd	..	Luxations.
	4th	..	Invaginations.
	5th	..	Herniæ.
	6th	..	Deviations.
Order 3.	7th	..	Foreign bodies.
	8th	..	Contractions and obliterations.
	9th	..	Dilatations.
Order 4.	10th	..	Hypertrophies and atrophies.
	11th	..	Metamorphoses and analogous productions.
Order 5.	12th	..	Dropsies and fluxus.
Order 6.	13th	..	Hæmorrhages.
Order 7.	14th	..	Gangrenes.
Order 8.	15th	..	Inflammatory lesions.
Order 9.	16th	..	Strumous lesions.
Order 10.	17th	..	Carcinomatous lesions.

The present volume contains only a consideration of the first six classes. That the above classification is extremely faulty, we should think, even its Author himself, would admit; but we believe a natural, and therefore perfect classification in our present state of knowledge to be impossible.

Under the head of wounds by pointed instruments is the following unique case:—

"Opening the body of a culprit I once found a very long rusty needle thrust from before backwards in the left ventricle near the apex of the heart. One extremity of the needle occupied the anterior walls; the other the posterior wall of this ventricle; the body of the needle was free in the cavity of the organ."

There was no means of ascertaining how it reached its position in the heart, for there was no trace of inflammation of the pericardium—no appearance of a cicatrix of the skin over the cardiac region.

Some instructive cases of rupture of arteries during efforts to reduce dislocations are detailed in the chapter on Solution of Continuity.

The causes of death by primary accidents are stated to be as follows:—

"1st The lesion of an organ indispensable to life; 2 Stupor; 3. Convulsions; 4. Hæmorrhage; 5. The introduction of air into veins."

The symptoms of the second mode of death are thus described:—

"The stupor of the wounded is a state of physical and moral insensibility,—of perfect indifference as to their position. The face is without expression, profound, altered, pallid, or jaundiced; the pulse is small, contracted, sometimes very slow; there is almost invariably present a sense of agony at the epigastrium."

The two cause of this stupor are:—1st. Extensive mutilations; 2d. Loss of vital power, the consequence of pain.

The stupor consequent on extensive mutilation may be independent of all concussion of the brain.

"In March, 1814, at the battle of Paris, I saw many men wounded by cannon-balls, perish in this stupor; they were placed beside their comrades, replied to questions with difficulty. Like the soldier of Quesnay, they would have been able to answer, if amputation had been proposed to them, 'that it was *no concern of theirs*.'"

M. Cruveilhier thinks that the moral condition of the individual wounded may have some influence producing or preventing the occurrence of death from stupor. Thus, it was common in 1830, among discomforted Royal Guard, while the victorious revolutionists much more rarely suffered from it. This form of stupor is altogether independent of

pain. In fact, there may have been no sensation of pain experienced at the time of the injury. But there is a form of stupor which may cause death the consequence of intense pain. Some case are here detailed, in which death appears to have been due simply to the nervous exhaustion consequent on the intense pain of surgical operations. The phenomena of the two forms of stupor are identical. The subject leads him to speak of etherization, and of it he writes—

"To have delivered humanity from the physical suffering which accompanies a surgical operation, is one of the greatest gifts of modern surgery."

M. Cruveilhier's account of the case in which he first saw the propriety of referring visceral abscesses after operation to phlebitis, is very interesting, but too long for us to extract.

The pus, he thinks, is formed in the vessels themselves, and carried into the capillaries, where it acts as a foreign body, and excites inflammation of those capillaries. Like all modern pathologists of repute, M. Cruveilheir repudiates the idea that pus globules can, as such, be absorbed by the capillaries, as a physical impossibility. The following is our author's account of the union of bone after fracture :—

"The callus is formed by the ossification of all the lacerated soft parts which surround the fragments, periosteum, cellular tissue, muscles, tendons, aponeuroses, &c.; the ends of the bone have no part in any period in the formation of the callus. *There are not two calli, one provisional, the other definitive*, but one and the same callus, spongy and voluminous in the first period, compact and reduced in size in the second."

In a chapter headed Reunion of Fractures by Cicatrix by Fibrous Tissue, it is stated that this mode of reunion is observed under two circumstances :—

"1st. In all solutions of continuity of bone with suppuration around the fragments. 2ndly. When the fragments of the fracture are not surrounded by the soft parts necessary for their consolidation."

So that the anatomical position of the neck of the femur accounts for the fact, that bony union never occurs when fracture takes places within the capsule. Firm fibrinous union, M. Cruveilheir believes, would take place, however, under such circumstances, if the immobility of the limb were secured. And this union would, under suder such circumstances, be so complete that a cure for all practical purposes would be effected. The following appears to us to offer a practical suggestion for the treatment of these unfortunate cases worthy of attention :—

"A fact which I observed gave me the idea that immobility in a sitting position might be, at least in some cases, much more favourable for the cure of fractures of the neck of the femur than immobility in the horizontal position. The sitting position, moreover, allows the patient to discharge his stools and urine without changing his position."

The case referred to is that of an old man eighty years of age, who has fractured the neck of the femur, when 400 leagues from Paris. He found himself so much easier in the sitting position, that he refused to leave his carriage at night while travelling to Paris, on reaching which city he was kept in a sitting position till the cure was complete. Seeing the ease with which many persons, suffering from heart affections, &c., bear the sitting posture for years, we think the hint exceedingly good and practical, and, as such, would strongly urge it on the notice of our readers. Under the head adhesions are arranged congenital adhesions constituting one group of monstrosities. This chapter is particularly full. We remember when the late Mr. Brookes exhibited, as a most singular phenomenon, the body of a youth, in whose abdomen the remains of a female fœtus had been detected, many persons of rank, unconnected with the Profession, went to gaze on the wonder. The sapient remark of one excited much merriment: "Eh! eh! Mr. Brookes," said His Royal Highness, "do you think he swallowed her." The labours of Geoffrey Saint Hillaire, father and son, Himly, Ollivier, and others, have done much to elucidate the subject.

From the chapter on Luxations we must be content with presenting to our readers the following case. In the text M. Cruveilheir throws doubt on the possibility of consecutive luxation of the humerus, but he appends this note :—

"At the moment when I arranged this Article, I imagined that consecutive luxation of the humerus was impossible, because I could see no cause fitted to produce that displacement; but I have just now seen a case which completely *refutes my theory*. A cook, aged 25 years, consulted me with all the signs of a subcoracoid luxation of the right humerus. Angular projection of the shoulder, subacromial depression, spheroidal prominence in front, beneath the coracoid process, formed by the head of the humerus, axis of the humerus outwards and backwards. I thought it was an old traumatic dislocation. It was nothing of the kind. She had suffered much from pain in the shoulder for a year and a half. For a year she had been unable to raise her hand to her head; four months had elapsed since she could put her hand to her mouth. No movement, when I saw her, was possible in the humero-scapular articulation."

Our space will not permit us to follow the distinguished Author through each chapter of the work before us, which will, when complete, contain a mass of materials such as no other work on the same subject can boast, and have, moreover, this advantage, that the materials are obtained from original researches, and not simply selected from apocryphal works or from nameless authors.

REPORTS OF SOCIETIES.

MEDICAL SOCIETY OF LONDON
Oct. 15, 1849.

F. Hird, Esq., President.

CHOLERA.

Dr. Clutterbuck commenced the evening's proceedings by saying: A great deal of discussion has taken place in this Society on rheumatism and hysteria, some calling a case one of rheumatism, and others denying that it was so. This could only arise from a great defect in our language; and, indeed medical language is most imperfect, vague, indefinite, and variously defined, and no greater service could be rendered to the Profession, than by ascertaining the true meaning of the words we use. Having stated this much, I shall now make some allusions to the subject of cholera, which, I think, has now some chance of being discussed with calmness. So far as at present, nothing more indefinite or uncertain as to the nature and treatment of the disease can possibly exist, and I should be glad to hear now the cool sentiments of gentlemen on the subject, as to what we are now to conclude on the nature and origin of the disease, and what we are to do as to the treatment of it. As to the latter point, nothing could have been so contradictory and vague as that suggested, and he felt convinced that the fatality of the disease had in many cases been increased by the remedies employed, at many times most violent in their nature, and some of which, if they had been applied to persons in health, would inevitably have destroyed them. Thus, calomel had been given in spoonful, and opium recommended in poisonous doses; but the patients having survived such treatment, that fact was taken as proof of the utility of the medicine. He was persuaded, however, that the *post hoc ergo propter hoc* would not apply to many of the cases in which it had been employed. When calomel was given largely in cases where the alimentary canal could contain nothing, one could imagine why it was evacuated; and so with other medicines. I think there can be no question that the disease is one of epidemic origin; but, allowing this, we are still no nearer as to what the disease really is. Then, as to its treatment; do we know enough of it, or of the effects of various kinds of treatment, to justify us in abiding by any particular course? I am inclined to think not. All that we can say is, that we have done no good, or that we have done positive harm. If I were asked my opinion on the treatment pursued, I should say, that it has proceeded on the supposition that we are unacquainted with the nature of the disease intrinsically, and that while we know so little, our observations do not carry us far as to treatment, but should tend to make us cautious. The conclusion to which I have come is, that the disease is incurable, that we have no specific remedy for it, and that, therefore, we must come to the palliative mode of treating it, relieving the symptoms by measures that are safe. Acting on this principle, and supposing that the case was one of vomiting, I should promote that to a reasonable extent, and the same with respect to the purging; I think it unreasonable to suppress it by opiates; and feeling this, I have used the mildest form of aperients, trusting that the natural indication is the proper symptom. Thus, after evacuation had gone on, then I might palliate to a certain extent, but still by the mildest means, endeavouring to restore the diminished animal heat, and trusting to time to effect the subsidence of the disease. On the question of contagion, that is a matter still open to a great deal of observation, and is involved still in much difficulty. We are hardly warranted in denying it, and yet we are met with much difficulty in allowing its contagiousness. Epidemics generally originate in some atmospheric change, and we are very apt to attribute them to malaria. But I think this is rather to be considered as an aggravating cause than the primary one. As a matter of theory, the thing is full of doubt and obscurity; we have nothing to rely on but careful observation and experience; and that, so far as I have observed, leads to the use of the mildest means for palliation, trusting to time to effect a cure. I make these observations for the purpose of eliciting further remarks.

Mr. Dendy: I join with Dr. Clutterbuck in thinking that our definitions are defective; and I would therefore ask him what he means by the term "cholera;" if it is the developed disease he alludes to, I am sure that "time" is not the thing to be depended on. If he speaks simply of diarrhœa, I might agree with him to some extent.

Mr. Headland: I concur most fully in the propriety of the Doctor's remarks on definitions, but would remind him that my doubt as to the case of rheumatism arose from my wish to adhere closely to medical nomenclature, which holds rheumatism to be a painful affection of the joints; and it was the absence of this feature in the case brought under notice which led me to doubt; and I must also remark that Dr. Clutterbuck has fallen into the very error he reprehends as to the cholera. The word implies very inadequately what we know of it; and to consider vomiting and purging as cholera is not a sufficient definition.

Dr. Clutterbuck: In my opinion we ought to look to that portion of the nervous system connected with the alimentary canal and the organs of digestion and of respiration; these appear primarily to be the suffering parts, and which are so violently disturbed.

Mr. Headland: Although we feel great insufficiency as to the treatment of cholera, yet it is impossible not to observe that great injury has been done to medicine by the circulation of statements that the Profession are wholly incompetent to it. In my opinion, the efforts of Medical Men have been most important in the late epidemic; and I think they have not been well used by the Government. They (I mean the College of Physicians) have been talked into certain plans; the knowledge they possessed has not been made use of: and I think that, so far from admitting that the Profession are not acquainted with the disease, we ought to teach the public that we are in possession of means for staying the epidemic. It has been said by some journals, who ought to have been the last to say so, that the Pro-

fession possesses no remedy for cholera; I would ask, do they possess any at all, except it be sulphur for Scotch fiddle? We have no specific for small-pox, or any malignant disorder. It happens that cholera is dependent on certain circumstances which we are ignorant of; but this is no more than holds as to measles and scarlet fever. Now, if the Profession can deal with a large mass of human beings, as in the metropolis, I think it fair to infer, that, with such a population as it contains, and where only 14,000 or 15,000 persons died, it is a monstrous statement to call it a severe visitation of a severe epidemic; and I think that, independent of medicine altogether, the moral influence of the Profession has been vastly useful; and that it is too much the custom of that Profession to be ridden over by those who had no right to do so.

Mr. Clarke (to bring the matter more specifically before the meeting) asked whether any gentleman had tried the calomel treatment of Dr. Ayre.

Dr. Bird: After all, I think that Dr. Clutterbuck and Mr. Headland are very much agreed. Why do we save so large a number of cases of typhus? —but simply that we do not kill our patients; and so it has been with regard to cholera. I do believe, with Mr. Headland, that the Profession has been a most important instrument in stopping the disease, and in preventing the seeds of it from finding a soil. With respect to Dr. Ayre's treatment, I confess, that, if that treatment is successful in Hull, the diseases of Hull and of London are very different things: I never saw it do one particle of good. Some, indeed, have recovered, but they rather got well in spite of the remedy than in consequence of it.

Mr. Hird: In the failure of some remedies, yet I think we have other measures at command. If we can keep up the vomiting, we by that means keep up the action of the heart, and this allows the system a longer period of time to overcome the effects of the poison.

Adjourned.

WESTMINSTER MEDICAL SOCIETY.

October 27, 1849.

F. Hird, Esq., President.

Mr. Henry Smith exhibited a specimen of a diseased knee which he had removed, by amputating the thigh of a young man aged 18. The patient had had a considerable enlargement of the bone for six years; it was seated over the inner side of the joint, and had latterly increased so as to materially affect the motions of the joint. It was considered to be an exostosis. No symptom of any disease within the joint itself appeared until three months previously, when an injury was received and the joint became inflamed; and, notwithstanding the employment of leeches, rest, and counter-irritation, the disease went on, and it soon became evident that the joint was seriously affected. As the patient was suffering very much, was completely crippled, and likely to remain so from the existence of the bony growth alone, Mr. Smith, at his urgent request, and with Mr. Fergusson's approval, removed the limb. The disease consisted of a great enlargement of the inner condyle of the femur, which was so soft as easily to allow the knife to penetrate. There was pus in the joint, and the cartilages were removed from the external condyle, and were in process of separation from the whole of the root of the articulating surface. He had performed the operation close above the knee-joint, by making a short flap in front, and cutting a long one behind from the muscles of the calf of the leg, as practised by Mr. Fergusson.

Mr. Hancock considered the disease to be of a scrofulous character, abscess in the cancellous structure; the bone was enlarged and ulcerated, and the cartilages absorbed. The form of operation resorted to by Mr. Smith was first introduced by Mr. Syme.

Mr. Canton considered, that if the disease had been simply an exostosis, it might have been removed without amputation of the limb; he had expected to find in the joint exhibited an increase of growth, but, instead, found a removal of the natural parts. The enlargement present was the result of irritation, periosteal disease, &c. It is a strong objection to this form of operation that numerous arteries have to be tied, an objection obviated by amputation higher up.

Mr. Smith said that it was a rule in operative surgery to take away as little of the healthy parts as possible; by making a flap from the calf of the leg, a greater extent of the thigh would be saved. Another benefit of this mode of operating, is that the cicatrix of the stump could be brought well forward, by careful attention to dressing. The great number of vessels divided was certainly an objection which could not be overlooked; in this instance about fifteen arteries required ligature. The young man was in perfect health, save from the local disease, and did not come of a scrofulous family.

Dr. Murphy read a paper "On the Use of Chloroform in Midwifery." He had carefully used it in many cases, in the hope of determining its value as an anodyne, and its immunity from mischief to the patient, three questions presenting themselves for consideration, viz.:—1st, Whether chloroform interfered with the action of the uterus; 2ndly, Whether the safety of the child is hazarded by its administration; and 3rdly, Whether any ill effects subsequently manifest themselves by which the safety of the patient is compromised. The cases selected for the use of chloroform were, first, operation cases, in which the diminution of the intense pain attendant upon them is of importance, and the anæsthetic is employed for a short time only; secondly, natural cases, in which he had at first restricted its use to cases of intense suffering, but latterly also to relieve pain in natural cases. The operative cases were thirteen in number,—ten being forceps cases, including one, the formation of a new os uteri; two cases of arm presentation, with unusual difficulties; and one case of perforation in a pelvis having a conjugate diameter of only $2\frac{1}{2}$ inches. The cases of natural labour were eight in number. The details of these cases are published in the Edinburgh Monthly Journal for November. In the operations the patients were rendered both insensible and unconscious, and, although, in some cases, they uttered sounds as if suffering pain, they said afterwards they had felt none. In one patient, greatly debilitated by privations, it being necessary to turn the child, the uterus contracted firmly. In the other case of arm presentation, the patient was rendered so deeply unconscious, that the voluntary muscles were relaxed, yet the uterus contracted with very considerable force. In the natural cases chloroform was never given to the extent of causing unconsciousness, and was reserved till the second stage of labour: it invariably diminished the intensity of the pains without altogether removing them, the patient feeling the pains, and bearing down with them, yet perfectly conscious of the relief she experienced. In one case no relief from pain appeared to result, but the contractions of the uterus were retarded. In every instance the mothers recovered most favourably. Three of the children died, one from perforation, one putrid, and one from extreme difficulty in turning.

He did not discuss the question whether anæsthesia should be employed in midwifery at all; but his observations were directed to solve the questions which concern the value of chloroform as an anæsthetic, and the dangers which may arise from its use. The results are briefly as follow:—The uterus was not paralysed in a single case. In one case, the period between the pains was lengthened, but the action of the uterus was more efficient. In another case, the labour appeared to be retarded, and the uterine contractions came on more quickly and forcibly when the chloroform was omitted; but in all the cases, its contractile power was by no means lessened. The 78 cases recorded by Dr. Channing proved the same. Dr. Denham, of Dublin, had found the cases protracted by chloroform, yet all progressed rapidly directly the anæsthetic was omitted; therefore, Dr. Murphy argued, that no paralysis resulted from the anæsthesia. Hæmorrhage is the result of atony or non-contraction of the uterus; yet, in 600 anæsthetic cases recorded, no such accident had occurred. The child was born alive in all of 541 natural births, and in 79 operative cases, 20 died from the performance of craniotomy; 8 only from other causes; a mortality of only 1 in 7 operative cases. In no instance had subsequent ill effects to the mother followed the use of anæsthesia. He confuted the statement, that ladies had died from its use, and attributed the deaths from convulsions, &c., in which chloroform had been used, not to the anæsthetic, but to other natural causes. All the deaths really caused by chloroform have occurred suddenly, and during the narcotism. The Author then referred to the researches of the American Medical Association, who reported, that anæsthesia had been used in 2,000 cases of midwifery without the occurrence of a single fatal case, and very few untoward results.

All medicines will occasionally produce evil results, and he considered the ill effects of anæsthetics merely to come under this category. The author lastly combated the assertion, that lascivious dreams accompany the inhalation of anæsthetics. He had never observed any such appearances, nor had other Practitioners. Having expressed his belief, that the intense sufferings of parturition are not physiological or normal, but pathological or abnormal, he considered the diminution of this pain to be not only justifiable but proper, and calculated to enable the constitution to recover itself much more rapidly than it otherwise would.

Mr. J. B. Brown was very favourable to the use of chloroform in labour when used properly. Its properties are—1st. Stimulating the nerves of motion; 2nd. Arresting sensation; and 3rd. Motion. The secret of administering it is to give small doses only so as to find these several stages. If the uterus is languid, and wants a stimulus, he gives chloroform, not secale cornutum; if the expulsive efforts require help, he gives it to the second degree. When gentlemen say, that they gave it for half an hour, they never consider whether they may not have given too much. He does not give it if the labour is perfectly natural, the os uteri dilating kindly, and the external parts moist; in other words, if there is not more pain than proper; beyond this, it is not justifiable to refuse it. In hard labour, or where bleeding and tartar emetic are indicated, he has never seen chloroform fail in giving relief. He referred to the refusal of some who object to its use, to try whether it is useful or not, and said, that neither he nor Drs. Murphy, Channing, &c., had ever found any lascivious actions during anæsthesia. Dr. Tyler Smith had experimented several times on guinea-pigs to prove the effect of chloroform on the nervous centres. The first effect was hurried respiration, and slight twitching of the extremities; then the animal lay still, and the motions were confined to movements of the diaphragm. Before death, he laid open the chest and abdomen, and found the heart beating, and the uterus and intestines moving peristaltically; the sphincters relaxed. He had pushed a stillette down the spinal marrow without producing movements of the limbs, thinking that perhaps the spinal marrow died with the animal. He experimented on frogs: they became quite insensible to spinal stimuli; they were beheaded, and the stillette passed down the spinal marrow, but no movements followed; when it was passed to the origins of the nerves there was a slight movement from those nerves; pinching the nerves had no effect, and galvanism very little. He thought these facts applicable to parturition; at first respiration is hurried; push the anæsthesia further, and you lose the spinal action, so that the uterus is left to its own peristaltic action; however the sphincters and voluntary muscles are paralysed, so that there is less resistance.

Dr. Snow said, that as the guinea pig must have been almost dead at the time of Dr. Smith's observation of its uterus, he doubted whether the result of the experiment could be applied to what occurred in practice. He agreed with Dr. Murphy that chloroform, when judiciously administered, does not interfere injuriously with the contraction of the uterus; but so far as he had been able to

observe, a full dose always had the effect of suspending the uterine action for the moment, and that, consequently, when relaxation of the uterus was required in order to facilitate turning the child, it could always be produced, by inducing a full state of narcotism, and continuing it till the turning was effected. He (Dr. Snow) had lately given chloroform, in a case of arm presentation, under the care of Mr. French, and the passive state of the uterus allowed that gentleman to turn the child with the greatest ease, although the liquor amnii had been some time discharged. In this case, the inhalation being discontinued, the uterus contracted almost immediately, and expelled the placenta into the vagina. In the case related by Dr. Murphy, where there was strong uterine action during the operation, Dr. Snow believed that the narcotism had not been so complete as it appeared to be, and had certainly not extended to the fourth degree. With respect to the alleged immoral effects of chloroform in midwifery, he, like Dr. Murphy, had seen nothing of the kind. The greater number of patients who underwent surgical operations had no hesitation in relating everything they experienced; but amorous dreams were so excessively rare under chloroform, in comparison with what occurred in natural sleep, that it was evident the inhalation exerted a powerful effect of the opposite kind to the one alleged; and he had no doubt that, if trial were made, chloroform would be found to be a more efficient agent in the prevention of chordee than belladonna, camphor, or any other medicine.

The discussion was then adjourned.

CASE OF POPLITEAL ANEURISM IN THE HOSPITAL AT CANTON.

[To the Editor of the Medical Times.]

SIR,—I observe, in a Number of the *Medical Times* sent me by a friend, that you state I have succeeded in opening a hospital, and residing *within* the city walls of Canton. I cannot conjecture how such a statement has got into the public Press; it may, however, have arisen from the fact that I have succeeded, after much difficulty, in establishing myself in the *western suburbs*, which is a great family neighbourhood, and where no foreigner has ever been able to reside before, being almost as much closed against foreigners as the city itself. By correcting the above error, which is calculated rather to harm than benefit the cause in which I am engaged,

I remain, Sir, respectfully yours,

BENJAMIN HOBSON.

Canton, July 24, 1849.

P.S. In the same Journal there was an interesting case of femoral aneurism, graphically and affectingly detailed. I copy from my case-book a similar one, affecting the popliteal artery. If you think it worthy of publication, you are welcome to the following rough notes.

August 11, 1848.—230 patients came under treatment. The most important was a case of aneurism of the popliteal artery. It commenced two months ago; at first very small, but increasing daily to the present size of a goose's egg. The patient, nor any of the assistants, were at all aware of its nature. One proposed opening it. Age 56; business, a cake-maker. The leg (right) is somewhat œdematous, walks with pain, knee bent; general health unaffected. Was advised to become an in-patient. The nature of the disease was explained to him, and perfect rest enjoined.

Aug. 15.—Returned, with his bedding and a relative. The tumour is gradually increasing in size. Pulsation distinct over a large surface; under perfect command, by pressure on the femoral artery. The man was put to bed, and Weiss's new screw tourniquet applied, which it was hoped might succeed in lessening the impulse of blood and gradually consolidating the tumour; and if this did not succeed, a gradual and occasional pressure upon the femoral would serve to open a greater collateral circulation around the knee, and thus give the patient a greater chance of success, if it was found necessary to tie the femoral artery. It was found, however, that even occasional pressure could not be borne without severe pain, so that cure by this means was abandoned as impracticable. The tumour beats strongly, is hot and tender to the touch. An operation, by tying the femoral, was now recommended as the only hope. The patient said he was willing, but wished his friends to be consulted first.

18th.—The aneurism is enlarging, is red and increasingly tender to the touch, projects much at one point, and the integuments there are very thin. The full permission of the friends being now obtained, whatever the consequences might be, it was decided, after consultation with Dr. Parker, to operate the following morning. The tourniquet was kept loosely applied over the femoral, ready to be screwed up at any moment by an assistant, who was ordered to be at hand. At 9 p.m. the same evening the aneurism suddenly burst. The blood was projected to a great distance, and about two pounds were lost, when the assistant rushed to the patient and pressed with all his might on the course of the artery till I could reach. The bed was covered with blood, thin and deficient in fibrine. The patient was in a half-fainting state, but quite conscious of his danger; great consternation was impressed on his own countenance, and that of the bystanders; my presence restored confidence. The tourniquet was screwed tight, and a handkerchief was tightly bound round the ruptured tumour. After consultation with Dr. Rowe, (Dr. Parker having been obliged to leave for Macea,) it was decided, all things considered, to be the best course to give the patient the chance of recovering, by tying the femoral, and amputating, if hæmorrhage or other urgent symptoms should seem to demand it. The operation I accordingly performed, kindly assisted by Dr. Rowe, between eleven and twelve p.m. The artery was secured without difficulty or bleeding, about the middle of the triangular space. The edges of the wound were brought together by suture and plaster.

The burst aneurism was slightly dressed and bandaged, the leg elevated, and foot clothed with flannel. Two grains of opium were given to calm the nervous system and to procure sleep. The patient bore the operation without a murmur, chloroform having been administered. This produced excitement at first, causing the poor sick man to laugh and talk in a very incoherent and irrelevant manner, which, at such a time, and with such a scene before us, was strangely out of character; but he soon became calm and motionless, and evidently suffered little, if any pain, during the operation.

19th.—Has had a good night; says he feels much more comfortable than before the operation. The rollers around the limb have become slack, showing that the swelling had diminished. The leg was warm, but the foot colder than the left. Pulse had risen, tongue dry. Changed the dressings and administered castor oil.

19th, p.m.—Going on well, bowels moved, free from pain. The tumour is beginning to slough away. Wound over the femoral artery healing by the first intention.

20th.—Had a favourable night; leg hotter than natural; foot still cold, but sensible to the warm touch of the hand; pulse full and quick; the skin hot, and tongue dry. Ol. ricini, ℥i.

21st.—Patient has been uneasy during part of the night, and is now feverish; tongue dry; pulse 120; thirst; no motion or urine passed for several hours. Gave an injection of hot water, and drew off the urine by catheter. Sent for Dr. Rowe. On dressing the tumour, we found that it had become very offensive, from the large slough that was separating; foot being still cold, had it gently rubbed with flannel, kept as warm as possible. Gave an effervescent saline draught.

8 p.m.—Still feverish. Dressed and carefully supported the limb; the bowels had been freely moved, and urine voided. Complained of pain all over the limb; tender to the touch; leg swollen; foot still cold; no discolouration; gave opium.

22nd, 4 a.m.—Great pain and tension of the limb: very tender near the knee, and upper part of the leg much more swollen; colder than natural; pulse 125; skin hot; countenance anxious; changed the dressings; the tumour has a dark sloughy appearance; very offensive; put the limb in an easy position, and gave opium.

9 a.m.—Mortification has evidently commenced in the foot. The skin is here and there discoloured, cold, and boggy to the touch. There are several elevations of the cuticle, filled with dark-looking fluid. Swelling has greatly increased, and skin is very tense and painful. Pulse 130, weak, and tremulous. Patient's mind is less clear, slightly delirious, restless, and uneasy.

11 a.m.—Had a consultation. Mortification was rapidly extending. The only hope was amputation. But the prospect of a successful termination appeared so slight, that we did not think it right to recommend it. The patient being very weak, the cellular tissue and skin all round the knee becoming discoloured and emphysematous, added to danger of secondary hæmorrhage on the ligature coming away, with the doubtful termination of an amputation. These things considered, could give little, only a bare hope, of saving the patient's life, insufficient to warrant another formidable operation, especially when it was considered, that if the patient died under, or immediately after the operation, the blame then would probably fall upon the surgeon, and prove detrimental to the interests of the Institution.

8 p.m.—Much the same. The whole leg is tense, dark and swollen. The tumour in the ham even in this stage appears gradually separating. Opium 1½ grains.

23rd.—The man is passing rapidly to dissolution. Pulse very quick and feeble; mind conscious. Mortification above the knee. The poor patient knew his fate; the friends and himself were both satisfied that everything had been done that could reasonably be expected, and expressed their gratitude. He was removed, by boat, to his residence at Fat Shan, a few miles off, and soon after he arrived there died. By this arrangement his friends were pleased, and the other patients in the hospital were free, and happy to continue in their ward. If the patient had died there, not one would have dared to remain in that room; and the beds would only have been re-occupied by new patients ignorant of the event. Chloroform has a very happy effect upon the Chinese. It was administered a short time since to a man whose arm was amputated from severe gun-shot wound of the hand. In another, in the dissection of a schirrus glandular tumour from the sub-maxillary region. In both these and other cases it rendered the patients quite unconscious of pain, and was not followed by the least ill effect; the taking of such a remedy is greatly in accordance with the wishes of the people, and disposes many to consent to surgical operations, who otherwise would not dare to submit to them.

Yours, &c.

BENJ. HOBSON, M.B., M.R.C.S.

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of Gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, 1st Nov., 1849:—Joseph Hughes Hemmings, Kimbolton, Hants; John Cox Lynch, Norwood; William Ferdinand Wratislaw, Rugby; Thomas Pettit Wright, Chatteris, Cambridgeshire.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College, at the meeting of the Court of Examiners on the 2nd inst:—Messrs. Robert Hamilton, Ipswich; John Thompson Goodrich, Paington, Devon; Richard Allanson Gaskill, St. Helen's, Lancashire; Charles Anthony Floyer, Floore, Northamptonshire; William Martin Hatfield, Chilham, Kent; Henry Taylor, Bury St. Edmunds, Suffolk; John Gilby Townsend Rossiter, Bristol; Thomas Croft, Bracknell, Berkshire; John Lascelles Nowell, Liverpool; Edward M'Kellar, Madeira; Samuel Reynold's, Debach, Suffolk; and Henry Dixon, Stockton-upon-Tees.

NAVAL SURGEONS.—At the last meeting of the Court of Examiners of the Royal College of Surgeons, Mr. William Evans passed his examination for Naval Surgeon. This gentleman had previously been admitted a Member of the College, his Diploma bearing date July 3, 1846.

THE FELLOWSHIP.—We understand, that, in consequence of the new regulations from the College coming into operation in the ensuing year, making it compulsory on all junior candidates presenting themselves for the honour, to undergo examinations in the classics and mathematics, a larger number than usual will present themselves for examination at the ensuing meetings on the 4th and 6th of December.

METROPOLITAN DISPENSARY. — Dr. Edwards Crisp has been unanimously elected Physician to this excellent Institution.

SOUTH LONDON MEDICAL SOCIETY. — Mr. Charles Taylor, of Camberwell, has just had awarded to him the prize of thirty guineas from this Society, for his "Essay on Infantile Remittent Fever, with especial reference to its Diagnosis from Incipient Hydrocephalus."

HEALTH OF LONDON DURING THE WEEK.—(From the Registrar-General's Return)—The mortality of London, which fell below the weekly average of five autumns, in the second week of October, has steadily continued to decline during the three subsequent weeks. The present return shows, that only 837 deaths were registered in the week ending last

Saturday, while the average is 1,162; (allowance being made for increase of population on previous years;) the decrease is, therefore, 325. A comparison of returns made for the same week, in the last ten years, shows, that, in any of the nine weeks, the mortality has not been so low as at the present time; in the corresponding week of 1841, the deaths were 840; in that of 1848, they were 1,115, after cholera had given warning of its presence Only 11 deaths from cholera were registered in last week; in the three preceding weeks they were successively 110, 48, and 25, declining by nearly a geometrical progression. Of the 11, one occurred in Lower North-street, Chelsea; two in the workhouse of St Martin-in-the-Fields (one having been that of a girl brought from a house in Bedfordbury, the condition of which is minutely described by the registrar); one in Claremont-place, Gray's-inn lane, one in George-yard, Saffron-hill; two at No. 12, Sevenstep-alley, Gravel-lane, one in the Lunatic Asylum, Hoxton-house, one in Maidstone-place, "a very low and ill-drained spot" in Haggerstone (East), one at 4, Paternoster-row, Spitalfields, where the mother of the deceased died five days afterwards of "diarrhœa," and one in Wycombe-place, Kent-road. In the last week 40 deaths were registered from diarrhœa and dysentery (the average is 27); in the three previous weeks they were 105, 63, and 51. Two of these in the present return occurred at Jenning's-buildings, Kensington, a locality which has frequently obtained unfavourable notice in the records of the late epidemic Typhus was fatal to 37 persons, the average is 56 Other epidemics are still under the average The mortality from small-pox and measles continues unusually low A woman of fifty-seven years died of "inflammation from a plum-stone lodging, thirty-three days before death, in the colon, and producing thickening and complete obstruction "—*Post mortem* In two cases intemperance is stated to have been the cause of death.

Continental Progress of Cholera.—The epidemic has now disappeared almost completely from the North of France, but it is spreading rapidly along the southern border of Europe, and extending from the territory of Algiers to the very heart of the African desert. To arrest, if possible, its ravages in Algiers, the French Government has ordered the troops to be dispersed in rural cantonments, wherever circumstances will permit of this mode of quartering the military The measure has been followed by excellent results, so far as regards the propagation of cholera, but, unfortunately, it cannot be carried to the fullest extent in Africa, because there the mortality—contrary to what is observed in civilised countries—is much greater in the rural districts than in the towns Still it does not much exceed 50 per cent on the attacks, which appears to be about the average in almost every part of Europe Thus the most recent accounts from Lombardy, through the *Mantua Gazette*, give the following results up to the 29th —

	Attacked	Died
Mantua	276	173
Milan	900	588
Bergamo	3028	1652
Brescia	851	495
	5015	2908

Showing a mortality of 57 per cent in these four towns.

Surrey County Lunatic Asylum.—There is a vacancy for a Medical man, well versed in the treatment of insanity, in this asylum. The office is called "*The Medical Superintendent of the Female Department*" Candidates must be married, between thirty and forty five years of age, Members of a College of Surgeons, and hold the license of the Society of Apothecaries. The emoluments are 350*l* per annum, with furnished apartments and coals

Percival Kirton, Esq, has been appointed Colonial Surgeon for the settlements in the Gambia

Middlesex Hospital.—A Quarterly General Court of the Governors of this Hospital was held on Friday last, when the Report of the Secretary stated, that the balance at the banker's was 1,148*l* 14s 8d, the balance from the Samaritan's Fund being 159*l* 6s 2d Within the last three months, 540 cholera out-patients had been attended; and 58 cases admitted into the Institution. During the quarter two legacies of 100*l*. each had been received, and another of 500*l* bequeathed, but not yet paid in At the suggestion of the lecturer, the Board had resolved that a lectureship on Comparative Anatomy be instituted at the School of Medicine connected with the Hospital.

Cholera.—The *Nouvelliste* of Marseilles gives the following details on the visitations of the cholera to that city.—"The first invasion, which commenced the 8th December, 1834, and finished the 1st April, 1835, carried off 2,741 persons, or an average of 24 per day. The second invasion commenced 12th July, 1835, and ended the 19th September of the same year, and carried off 4,532 persons, or an average of 70 a-day. The third invasion commenced the 19th August and ended 11th October, 1837, and caused 2,460 deaths, or 47 per day. The fourth invasion commenced the 6th August, 1849, and up to 25th October caused 3,502 deaths, or 44 per day The duration of the cholera on its four visits has been 314 days, the total deaths 13,235, the average per day 42 The average deaths per day, in ordinary times, is 15"

Obituary.—June 19, Surgeon John Ross, Residency Surgeon, at Bagdad—Sept 9, at Barrackpore, Surgeon C Llewellyn, M D, 40th Native Infantry —Aug 27, at Lahore, of apoplexy, Assistant-Surgeon George Thomson, M D, 3rd Brigade Horse Artillery —Nov 1, Dr Henry Graham, of Edinburgh—Oct. 29, William Brice, Esq, aged 32, late Assistant-Surgeon of H M S. Blazer.—At Brinklow, on Sunday, the 4th instant, in his 31st year, Francis Allcock Oldaker, Esq, M R C S

Public Hygiene.—Beneficial results have already begun to show themselves, from the late scourge of cholera which we have experienced Those hot-beds of fever and disease, the dwellings of the artisan, in populous towns, but more particularly in London, have become exposed to public gaze and public reprobation, is alike destructive to health and morality We have at length begun to perceive, that their pestilential character affects, not only their unfortunate inhabitants, but the community at large, and, unless the evil be met and remedied, the social as well as the physical state of the country may become endangered The extensive parish of Lambeth, in vestry assembled, have unanimously determined on providing public baths and wash houses for the working-classes This is a step in the right direction But, they must go further, or their efforts will prove futile They must not allow the washed to return and "wallow in the mire" Water must also be conveyed to the humble dwelling, and, above all, closets either public or private, must be provided. The want of this accommodation has, perhaps, been more mischievous in its effects, in every way, than the want of water In a recent lecture at King's College, allusion was made to the use of peat charcoal, as the most simple effective, and cheapest method yet brought forward for the accomplishment of this reform, and the high authority of the parties making the suggestion, should most seriously draw the attention of the public to the means suggested Experiments were performed before the Medical Society of the above College by Mr Jasper Rogers, which fully proved the soundness of the principle in question, and that it was *not* one of the many quackeries of the present day We hear that the town of Windsor contemplates adopting the plan, and that Mr Rogers is in communication with the Board of Health there on this important measure We shall watch with much interest the application of this principle on an extensive scale

Revolutions and Insanity.—The agitations of the last two years have, according to the reports of medical officers, increased the number of cases of mental disease to an extent far beyond the average of former years, the fact is proved by the returns from all the lunatic asylums of Germany The same result was observed in France in 1848 Such is the statement of the *Times'* Correspondent It has long been known, however, that in seasons of great political excitement cases of insanity more frequently occur This was noticed in the French Revolutions of 1792 and 1830, as well as in 1848

Asylum for Idiots.—A General Meeting of the supporters of this Institution was held last week at the London Tavern, Alderman Sir George Carroll in the chair The Report of the Directors for 1849 gave a very favourable review of the progress of the Institution Drs Conolly and Little had given their gratuitous services as physicians, and the services of Drs Forbes and Sutherland, and Sir J Clark, were mentioned in warm terms The patients in the Institution were divided into two classes—those elected, and those who were paid for The charges were varied, from 25 to 50 and 100 guineas per annum, according to circumstances, but the paid patients were all on an equal footing—had first-class rooms, and best diet, while every branch of education, however expensive, was open to them all A marked improvement had taken place in the condition of many of these helpless beings. The present premises did not afford sufficient accommodation, and it was necessary that another house should be provided, as there were several paying patients waiting for admission, in addition to those to be elected that day His Royal Highness Prince Albert, and His Royal Highness the Duke of Cambridge, had recently honoured the Asylum by their presence, and expressed great satisfaction at the arrangements adopted. Correspondents from the most distant countries had been invited to witness the operation of the charity. The meeting then proceeded to the election of 12 candidates, from a list of 152. The names of the successful candidates were declared at the close of the poll, and the meeting separated, after a vote of thanks to the Chairman.

Rapid Bronchotomy.—M. Chassaignac, Surgeon to the Hospital Saint Antoine, at Paris, lately performed the operation of tracheotomy on a child affected with croup, in the following expeditious manner —The larynx was steadied by thrusting a tenaculum through the cricoid membrane and the skin; the subjacent tissues and the rings of the trachea were then divided by one cut of an ordinary pointed bistoury. When a canula is not immediately at hand, Monsieur Chassaignac passes through each lip of the wound a thread fastened to a needle thrust through a fold of skin on either side of the trachea.

Intra-Uterine Crying.—Professor Vannoni has just published, in a Florence paper, two cases, which tend to establish the possibility of fœtal intra-uterine crying. The Professor explains the phenomenon by the penetration of some of the air accumulated in the ovum into the trachea of the fœtus.

The Parisian Medical Session, which commenced on the 2nd November, presents little promise of being a brilliant one. Medical affairs, as well as all others, are dull to an extreme, and the hospitals and hotels suffer from the momentary collapse The former are full of patients, but all the medical celebrities have retired to the country, and treat their patients by proxy The hotels, on the contrary, are empty of students, and for the most part tenanted by their masters alone, a very unprofitable species of occupancy. Here and there in the *Quartier Latin*, a lank American or a stray English doctor, may be seen, but that once busy and joyous quarter is now comparatively a desert; hardly a French student is to be met with in its once crowded streets, and the establishments which they were wont to support, are now closed, or rapidly falling into decay This unfortunate state of affairs depends partly on the competition of the provincial Schools of Medicine, but mainly on the circumstance, that parents are unwilling to expose their children to the danger of a residence in Paris during these troubled times of disorder or insurrection,—and they are right Amongst the 15,000 prisoners cast into the forts, or buried in the caverns of the Thuilleries, after the affairs of June, were many hundreds of medical students, many have never been heard of since those terrible days, while the majority, without the shadow of trial or judgment, condemned by the military tribunals, were transferred to the *pontons* and thence transported to Africa. It will, indeed, be a long day before the country can recover the effects of that civil battle, or of the re-action, scarcely less fatal, which followed it. The monotony, however, of the Parisian Medical campaign will be somewhat relieved on the 15th of the coming month, by a *concours* for the chair of operative surgery, which has recently been added to the faculty of medicine. The *concours* will, it is expected, be a brilliant one, and bring forth nearly all the young surgeons of any pretension

Medical Geology.—A paper was lately read before the American Association for the Advancement of Science by J A Lapham, of Milwaukie, founded on a suggestion of Dr. Jackson, that cholera rages with peculiar violence in limestone districts. The limestone rock is entirely denuded in Sandusky city, soil enough to support shade trees does not exist, and here, out of a population of 2500, the deaths varied from 12 to 33 daily, equivalent to 6000 daily for the population of New York No bad illustration of the great leaps to conclusions which men take when they hunt for notoriety.

The Polar Plant.—Major Alvord has discovered a singular plant of the Western Prairies, said to possess the peculiarity of pointing north and south, and to which he has given the name of Silphium Laciniatum No trace of iron has been discovered in the plant, but as it is full of resinous matter, Major Alvord suggests its polarity may be due to electric currents

Plants of Wisconsin.—This region was first explored by Nuttall in 1816 In 1821 Messrs. Douglass and Torry published in *Silliman's Journal* the characteristics of the plants The last notice is in Schoolcraft's Narrative of an Expedition through the Upper Mississippi to Itasca Lake in 1832. The present enumeration contains 111 natural orders, 416 genera, and 840 species. Professor Gray considered the Flora as identical with that of the Great

Lakes, except in the north, where the Alpine character appears.

ZANTHIDIUM OF EHRENBERG.—Professor Agassiz maintains, that the zanthidium is not an animal, as supposed by Ehrenberg, but a plant of the family of algæ, and that the granules, considered by Ehrenberg as eggs, were, in reality, the seed capsules. The entire capsule consists of beautiful hexagonal cells. Professor Gray remarks, that it differs from any genus of the proper algæ that had fallen under his notice.

RELATIVE VALUE OF DIPLOMAS.—A contest is going on amongst some of the physicians of a country town (celebrated for giving a title to one of our dukes, and for its rich charities) for the office of Physician to the Infirmary. In a newspaper advertisement, one of the candidates appends to his name the following titles:—M.D., Graduate of the University of Edinburgh, Licentiate of the Royal College of Physicians of London, Fellow of the Royal Medical and Chirurgical Society, late Physician to the Metropolitan Free Hospital, formerly Physician to the Westminster General Dispensary, also Physician to the Chelsea, Brompton, and Belgrave Dispensary; Honorary Physician to the Shropshire Eye and Ear Infirmary, Member of the Royal Institution of Great Britain, Author of practical Observations on Cataract and Closed Pupil, On Amputation of Arm at the Shoulder joint, and on Compound Fractures Illustrated by cases. In another advertisement, the same Physician gives reasons why the Degree of M D., obtained from the University of St. Andrews "is but lightly esteemed, as evidence of superior medical attainments." We hope some means will soon be adopted to make medical education in this country more uniform, which will do much to annihilate this strife about superiority of Degrees. Why should not candidates for hospital appointments have their professional knowledge practically tested?

COPAIBA CAPSULES.—Capsules are occasionally to be met with in the market, purporting to be copaiba capsules, but which do not contain one particle of the balsam. A Correspondent informs us, that he examined some of these spurious articles, and found that they were filled solely with train oil. He further states, that his experience in this matter has been confirmed by that of others. The fraud in this instance is very reprehensible, and the dealers ought to be punished.

PROTECTION OF LIFE IN SEWERS.—At a meeting of the Metropolitan Commission of Sewers, on Friday last, Captain Dawson brought forward the plan of a very ingenious contrivance sent to him by Mr. E. Lebethan, for the protection of life in sewers. The contrivance consists of a helmet constructed like that worn by divers, and which is connected with a chamber placed on the back of the sewersman, containing a reservoir of condensed air. It was referred to the General Committee for examination.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Nov. 3, 1849.

CAUSES OF DEATH.	Total	Average of Five Autumns.
ALL CAUSES	837	1162
SPECIFIED CAUSES	834	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	211	307
SPORADIC DISEASES		
Dropsy, Cancer and other Diseases of uncertain or variable seat	37	49
Tubercular Diseases	162	178
Diseases of the brain, Spinal Marrow Nerves, and Senses	93	125
Diseases of the Heart and Blood vessels	28	40
Diseases of the Lungs, and of the other Organs of Respiration	120	211
Diseases of the Stomach, Liver, and other Organs of Digestion	48	65
Diseases of the Kidneys, &c.	13	11
Childbirth, Diseases of the Uterus, &c.	8	11
Rheumatism, Diseases of the Bones, Joints, &c.	2	8
Diseases of the Skin, Cellular Tissue, &c.	1	1
Malformations	3	4
Premature Birth and Debility	16	23
Atrophy	21	18
Age	38	57
Sudden	10	12
Violence, Privation, Cold, and Intemperance	20	36
Causes not Specified	3	4

The following is the number of Deaths occurring from some of the more important special causes:—

Apoplexy	11	Heart	37	Phthisis	113
Bronchitis ...	34	Hooping-cough	33	Pneumonia ...	70
Cholera.........	11	Hydrocephalus	27	Scarlatina	41
Childbirth	3	Influenza	9	Small-pox	9
Convulsions...	31	Liver	14	Stomach	6
Diarrhœa	31	Lungs	4	Teething	6
Dropsy	18	Measles	16	Typhus	37
Erysipelas ...	6	Paralysis	26	Uterus	4

DRAINAGE OF LEEDS.—The Town Council of Leeds, which but a little while ago dismissed the sewerage question by a *sine die* postponement, has now resolved to have the whole of the town thoroughly drained. It will be effected by means of a main trunk sewer, which will be carried under the bed of the river Aire, and extend beyond the boundary of the borough, towards the south-east, where it will have an outlet for the sewerage in the lands belonging to Mr. Dugram, of Temple Newsam.

TO CORRESPONDENTS.

THE QUARTERLY RETURN OF THE REGISTRAR-GENERAL—This valuable document came to hand too late in the week for us to give it the requisite attention; but in our next Number it shall receive our careful consideration.

"A Young Practitioner" consults us as to the safest and and the surest road to success. We reply—"Think much little.

"Studens."—We wish Studens would refer to his books. For once we reply to him. 1. In the Arctic regions distant objects are comparatively clearer, and sounds are heard at a greater distance than in other climates. 2. In air sound travels at 1142 feet per second; in water, at the rate of 4709 feet per second.

"Mr Bulley's" cases of "Billous Cholera treated by hot water applications to the abdomen will appear in our next number

If "O. Z." will favour us with an address where a private letter may find him, we will write to him. In the mean we reply to his questions. No. 1. Almost invariably. No. 2. Certainly not. No. 3. Certainly not. No. 4. Probably not.

"A Constant Reader" is recommended to apply to the Medical Protection Society, at their office, 48, Lincoln's-inn-fields, London.

"Mr. O'Neill's" application has been received and answered.

"A.B.C."—We have not lost sight of Mr. Clay's work on "Ovariotomy." We take blame to ourselves for not noticing it earlier.

"Smoke."—"The juice of cursed hebenon" was probably the essential oil of tobacco; since we learn from old Gerarde, that, in Shakspeare's time, tobacco was commonly called henbane of Peru. We quite agree with King James, that "smoke becomes a kitchen fire better than a dining chamber; and yet it makes a kitchen oftentimes in the inward parts of men, soiling and infecting them with an unctuous and oily kind of soote." "It is a custom," continues His Majesty, "loathsome to the eye, harmful to the brain, dangerous to the lungs, and in the black, stinking fume thereof, nearest resembling the horrible stygian smoke of the pit that is bottomless."

Mr. H. Hughes' Work, to which our Correspondent alludes, we have not yet received.

"Mr. Moyle's" letter, and "Mr. Leithead's," on Mr. Ebsworth's views of the communicability of the Cholera Poison from man to man, have been received, and will have our early attention.

"Mr. Daniell, of Newport Pagnell," must receive our apologies for an oversight.

"Mr. Dalrymple" writes us as follows.—"Sir,—I will thank you to correct an error which has crept into your report of some observations of Dr. E. Crisp at the Medical Society of London, on the 8th ult., and which appeared in your Journal of the 27th ult. Dr. E. Crisp is there made to say I had 'recognised as the larvæ of snails' certain vomited matters. The fact is, Dr. E. Crisp showed me some objects which had been vomited by a young lady, and which, for some time, had been believed to be living entozoa. It having been positively stated that these bodies moved when first rejected and on being placed in warm water, I immediately recognised these bodies as the generative organs of the snail, and referred Dr. Crisp to the little calcarious body to be found in the bulbous portion of these organisms. The explanation was simply that the generative organs of the snail being particularly firm, and almost of cartilaginous hardness, had not been as easily digested as the softer bodies."

"A Young Psychologist" writes to know whether insanity may be produced by an injury to the head, and how long before morbid symptoms are developed. It is possible for blows on the head, at first followed by symptoms of concussion or compression, afterwards to produce mental alienation. This may vary in degree, from a slight peculiarity of character, to the most serious dementia. Morbid mental symptoms may not be immediately developed after the receipt of an injury, for years have been, in some cases, known to elapse before the mind has become disordered. In some cases, however, blows on the head, so far from producing insanity, have been known to improve the mental powers

"G M, Boston," asks the best method of ascertaining the density of urine. By employing the urinometer, an instrument originally suggested by Dr. Prout. It has a scale divided into 60°, the zero being the point at which it floats in distilled water. The numbers on the scale, added to 1,000, give the various specific gravities Thus, if the instrument is placed in urine, and the number cut be 30, the fluid has a specific gravity of 1,030.

"Leonard."—A good plan for detecting a small quantity of nitric acid in a liquor, is, to neutralize the acid with a solution of potash, and evaporate to dryness The salt crystallizes in sharp needles, and deflagrates, when placed on ignited charcoal, heated with a little bisulphate of potash and some copper filings, it evolves copious red flames, and, with a drop of sulphuric acid and a crystal of protosulphate of iron, an olive coloured ring is formed.

"Chirurgus" inquires how long it is possible for a person to exist without food. It will depend greatly whether he has access to any liquid to relieve the intense thirst commonly experienced. A very small quantity of water is capable of prolonging life.

"Amicus."—A person desirous of having a house licensed for the reception of lunatics, must, if such house be in the jurisdiction of the Commissioners in Lunacy, give notice to them, if elsewhere, to the Clerk of the Peace for the county or borough in which the house is situated, fourteen days prior to some quarterly or other meeting of the Commissioners, or to some General or Quarter Sessions for the county or borough.

"Mr. R. C. Browne, of Tamworth," in returning our Cholera Table, writes as follows.—"I have had 171 cases of English cholera and diarrhœa, and after two or three doses of calomel and opium, found the best effects, where sickness and diarrhœa remained, from two drops of hydrocyanic acid and ten grains of soda and creta every two or three hours. I have also found it very useful in the febrile state in allaying pain and irritation of stomach externally, in the proportion of eight to ten drops of acid hydrocy. to ℥i. of water applied by means of rags dipped in it."

"Singleton's Ointment."—We are obliged by our Correspondent's polite note, and shall be glad to hear from him upon the subject.

"An Old Subscriber," dating from Hampstead-heath, inquires for the best and most comprehensive work on skin diseases. The best work hitherto published, that of Dr. Burgess, is confined to the eruptions of the head and hands. Mr. Erasmus Wilson's will, probably, when finished, be the most comprehensive.

We are obliged this week for want of space to leave unanswered many esteemed correspondents.

ERRATUM.—In the "Statistics of Cholera" in our last, p. 350, col. 1, line 5 from the bottom, for "the *least* in one day," read, "the next less in one day."

ORIGINAL LECTURES.

LECTURES ON THE CHEMISTRY OF THE POISONS; OR, ON PRACTICAL TOXICOLOGY.

SHOWING THE APPLICATIONS OF CHEMISTRY TO THE DISCOVERY OF CRIME.

By H. LETHEBY, M.B., Lond: Lecturer on Chemistry at the Medical College of the London Hospital.

LECTURE IX.

Modes of purifying sulphuric acid.—Dupasquier's method.—Haye's process.—Difficulties connected with the distillation of the acid.—Ure's directions.—Lembert's directions.—Process of rectification to be adopted in actual practice.—Fraudulent uses of sulphuric acid and its salts.—Adulteration of vinegar and wine.—Modes of discovering the fraud: Orfila's, Lassaigne's, Ure's.—Alum and other sulphates in bread.—Production of starch sugar, and its employment in the adulteration of cane sugar.—Modes of recognising the fraud.

MODES OF PURIFYING SULPHURIC ACID.

On considering the nature of the impurities which commonly exist in crude oil of vitriol, it will be evident to you that the contaminating agents cannot be entirely removed by simply distilling the acid, inasmuch as many of them are volatilized at about the same temperature as that at which the acid itself boils. It is necessary, therefore, either to fix these impurities, or to decompose them before we submit the liquid to such an operation; and several suggestions have been offered in the hope of effecting one or other of these desirable objects; for instance, Dupasquier asserts that the earthy and alkaline sulphurets afford an easy and a certain method of decomposing two of these impurities—namely, nitric and arsenic acids. He states, moreover, and so does Mr. Reuben Phillips, that the sulphuret of barium is best suited to this purpose; and he recommends it to be employed in the following manner:—

Take the crude acid from the leaden chamber, and dilute it with water until its density is about 1350. If we employ it much stronger than this, the precipitates hereafter to be formed in it do not subside very readily. Apply heat to the liquid, and when its temperature has risen to about 212° of Fahrenheit, stir in a portion of crystallized sulphuret of barium. Allow the precipitate thus formed to subside, and carefully remove the supernatant clear liquor, in order that it may be concentrated, and further purified by a subsequent distillation. The *rationale* of the operation is the following. When sulphuret of barium (Ba.S) is thrown into dilute oil of vitriol, some of the water (H O) of the acid is decomposed, and, by reason of a mutual re-action, or, interchange of elements, baryta (Ba O) and sulphuretted hydrogen (H S) are produced. The former compound immediately unites with sulphuric acid, and is precipitated as an insoluble sulphate (Ba O, S O3) while the latter escapes in a gaseous form; and, meeting with arsenic acid, it re-acts on this impurity, and produces an insoluble sulphuret of arsenicum, which, with the sulphate of baryta before-mentioned, is deposited as a flocculent yellowish white precipitate. The quantity of sulphuret of barium required for the purification of the acid must depend on the amount of arsenic contained in the liquid; and, therefore, some preliminary trials must be made in order to determine this point. As a general rule, however, Dupasquier has found that one part, or at most, one part and a half of the sulphuret is quite sufficient for the purification of 500 parts of arsenical sulphuric acid; and he recommends the use of the crystallized sulphuret, upon the grounds that its decomposition is more slow and steady, and that the liberated gas is, therefore, enabled to act for a longer time, and to a greater extent upon the arsenical impurity. You may, however, have to encounter some difficulty in procuring the crystallized salt. Under such circumstances, I advise you to resort to the common sulphuret of this base,—a preparation which is easily obtained by igniting a mixture of sulphate of baryta and wood charcoal. In point of fact, you will find that this very accessible compound is in every way suited to the purpose intended, and that it will readily dearsenicate a large portion of impure acid at one operation. To procure this sulphuret you are to mix sixty parts of powdered sulphate of baryta with thirty of wood charcoal, and ignite the mixture for ten or fifteen minutes in a well covered crucible, taking care that the ignition is complete, and that the atmosphere is properly excluded. If you do not attend to the latter precaution, the sulphuret will be again oxydised and converted into sulphate of baryta, which is an inert compound. A second mode of purifying the crude acid has been recommended by Mr. Hayes, an American chemist; but I apprehend that the process is too uncertain, and too difficult of management for very general use. I will, however, give you an outline of his mode of operating. He takes the acid at once from the leaden chamber,—when, as he says, it contains sulphurous acid, muriatic acid, hyponitric acid, arsenious acid, oxides of lead and iron, alumina, lime, soda, and organic matter; and to this impure acid he adds a little nitrate of potash, which destroys organic matter, and raises the sulphurous and arsenious acids to a higher state of oxydation. He then adds about the 1-300th part of sulphate of ammonia, which removes any trace of hyponitrous acid. After this, the liquid is evaporated, until it reaches a density of 1780, and when cold, it is poured into deep leaden vessels, which are kept at a temperature of 32° Fahr. Here the insoluble impurities of the acid subside; and when the supernatant liquor has become perfectly clear, it is run off into shallow lead vessels, which are cooled down to the temperature of zero. By this means the acid is frozen, and large crytals of the binhydrate of sulphuric acid are formed. When these have increased so as to about half fill the vessel, the unfrozen portion of the liquid is rapidly poured away, and the crystals are washed with some acid of a former freezing. These crystals, according to Mr. Hayes, afford, on melting, an acid which is nearly pure.

The acids obtained by the foregoing processes have yet to be distilled, before they can be regarded as pure; for they may still contain certain saline matters which have not been eliminated during any of the operations to which they have been subjected; and in order to effect this you must proceed with considerable caution. "I take," says Dr. Ure, "a plain glass retort, capable of containing from two to four quarts of water, and put into it about a pint measure of sulphuric acid, and a few fragments of glass, connecting the retort with a large globular receiver, by means of a glass tube four feet long, and from one to two inches in diameter. The tube fits very loosely at both ends. The retort is placed over a charcoal fire, and the flame is made to play gently on its bottom. When the acid begins to boil smartly, sudden explosions of dense vapour rush forth from time to time, which would infallibly break small vessels. Here, however, these expansions are safely permitted, by the large capacity of the retort and the receiver, as well as by the easy communication with the air at both ends of the adapter tube. Should the retort, indeed, be exposed to a great intensity of flame, the vapour will, no doubt, be generated with inconceivable rapidity and break the apparatus. But this accident can proceed only from gross imprudence. It resembles, in suddenness, the explosion of gunpowder, and illustrates admirably Dr. Black's observation, that, but for the great latent heat of steam, a mass of water, powerfully heated, would explode on reaching the boiling temperature. I have ascertained that the specific caloric of the vapour of sulphuric acid is very small, and hence the danger to which rash operators may be exposed during its distillation. Hence, also, it is unnecessary to surround the receiver with cold water, as when alcohol and most other liquids are distilled. Indeed, the application of cold to the bottom of the receiver generally causes it, in the present operation, to crack. By the above method, I have made the concentrated oil of vitriol to flow over in a continuous slender stream, without the globe becoming sensibly hot."

A modification of this process has been recently recommended by M. Lembert, who says, "I introduce into the retort some pieces of *quarzite*, a variety of granulated quartz, resulting from the conglomeration of particles of that substance, probably under the influence of a high temperature. It is important to choose this variety, the others giving far less satisfactory results. The shape of the pieces is by no means a matter of indifference, with reference to the success of the process. I have remarked in a great number of distillations, that the fragments obtained by striking on the edge of a former cleavage facilitate the distillation better than very thick pieces. The number, as well as the size of the pieces, must also be observed. If they are too small, and in too small a quantity, the bumping may occur, because the fragments are easily lifted by the vapour which is disengaged; consequently the bottom of the retort, being no longer covered with the siliceous substance, assumes the condition of a smooth vessel, and the vapour is produced with difficulty. If they be small, and in too great quantity, the ebullition is irregular, bumping occurs without distillation, bursts of vapour take place at intervals, the liquid rises in the retort; and if the latter be rather full, it may pass over into the neck. The fragments should be at least a centimetre (one-third of an inch) in length, for the operation to succeed well. I use them generally as large as the neck of the retort will allow. Ten or twelve scales of *quarzite* of this size are sufficient to distil readily several pounds of acid. It is well to cover the retort,—that is to say, to distil in a reverberatory furnace, furnished with a dome; without this precaution, the distillation would proceed very slowly, although the ebullition might be very brisk, because the vapour of sulphuric acid being very heavy, and only existing at a high temperature, would condense before reaching the neck of the retort. This process, which is very simple, is especially advantageous, since it may be applied to the distillation of many other liquids. In fact, the substance employed to facilitate the ebullition is unalterable by nearly all chemical agents, and for the last three or four years I have employed it in nearly all my distillations.

In the process just described, the quarzite acts by its numerous rough surfaces in facilitating the formation of the vapour; but theory shows that the same result might be obtained, that is, the distillation without bumping, if the acid could be made a better conductor of heat. To this end, M. Lembert proposes to dissolve from one to two ounces of sulphate of potash, or of well dried sulphate of soda, in each pint of the oil of vitriol, and then to distil over about two-thirds, or at most three fourths, of the acid, leaving the remainder in the retort to be mixed with more acid for another operation. If the distillation be carried beyond this point there is some danger to the retort; for the temperature at which the liquid boils rises in proportion as the acid solution becomes more concentrated; and if it be concentrated too much, that is, if the distillation be carried too far, there would remain little more than the bisulphate of the alkali; under which circumstances the residue would become so hot as to endanger the solidity of the glass. In fact, the softening and bulging out of the retort will often take place even at an earlier stage of the process than this is.

Of these two processes, says M. Lembert, I prefer the first; and although it may be sufficiently efficacious, since those to whom I have shown it, and who have practised it, have been astonished at the facility with which the acid distils by this method, yet the process may be rendered more easy still by combining the two, that is to say, by putting into the cucurbit both the sulphate and the quarzite. Then, except the elevation of temperature, the sulphuric acid boils as easily and with as much regularity as water.

There are, however, two precautions connected with this process, which I ought to mention to you. First, you are not to distil your acid too frequently from the same quarzite; for the angles and points of the mineral are very liable to become rounded; and, secondly, do not expose the neck of the retort to currents of cold air; for if you do so, the sudden

alteration of temperature will infallibly break it. Every time, says M. Lembert, that my retorts have been broken in distilling sulphuric acid, the accident has happened in this way. Lastly, I ought to inform you of the results of Mr. A. Rose's investigations into this matter; for he has examined the subject with great care, in order to discover a means of separating the compounds of azote and oxygen from sulphuric acid. This chemist states, that when strong oil of vitriol, holding binoxide of nitrogen and nitric acid in solution, is distilled, water and nitric acid first pass over into the receiver, then follows pure sulphuric, and lastly sulphuric acid and binoxide of nitrogen are vaporised. If, however, the oil of vitriol be diluted with about twice its bulk of water before it is introduced into the retort, then the nitric acid, water, and binoxide of nitrogen of the liquid are the first products of its distillation, and by changing the receiver as soon as these have flowed over, pure sulphuric acid may be collected until the process is at an end.

I have been thus minute in recounting the experience of our most practical chemists, and in detailing the processes which have been suggested by them for the purification of oil of vitriol, in the hope that you may fully perceive the difficulties connected with the subject, and be enabled to deduce such an amount of information therefrom, as will enable you to conduct these operations with safety and success; for, as I need hardly tell, however cautious and careful you may have been in making choice of the sulphuric acid to be employed in your analytical researches, you will frequently be perplexed by an inability to obtain a strictly pure article; and under these circumstances you are compelled to rectify the acid for yourselves.

Taking advantage, therefore, of the various suggestions which have been offered to us, we may proceed to purify sulphuric acid in the following manner:—Take the crude oil of vitriol of commerce and mix it with twice its bulk of water; this will produce an acid having a specific gravity of about 1350, and the mixture will acquire a temperature of about 200° of Fahrenheit. Into this you are to stir, while it is still hot, the requisite quantity of sulphuret of barium; and I recommend you to use five grains of sulphuret for each fluid ounce of the crude oil of vitriol employed. Allow the mixture to stand for twenty-four hours, during which time all the solid impurities will have subsided, then pour off the supernatant liquor, and distil it in a capacious retort, using the precautions recommended by Ure and Lembert; that is, to distil it, with some fragments of glass or flint, in the retort, to cover the vessel with a hood or cone, in order that the vapour of the acid may not be cooled before it reaches the neck of the vessel; and lastly, to change the receiver when you have drawn off a little more than one half of the liquid; for, as I have already said, the first portion consists of water, sulphurous acid, nitric acid, and binoxide of nitrogen; and it is only after these have been removed that pure sulphuric acid begins to distil over.

Should the acid thus obtained be still contaminated with a small quantity of sulphurous acid—an impurity of some moment to you as medical jurists, you can very readily dispose of the perplexing agent by adding a few grains of pure nitrate of ammonia. You must take care, however, that you do not add too much of this oxydizing agent, or you will render the liquid unfit for employment in Marsh's apparatus.

FRAUDULENT USES OF SULPHURIC ACID.

Sulphuric acid and the sulphates are not uncommonly employed as sophisticating agents; for example, alum and sulphuric acid are used for the purpose of increasing the acidity of wines and vinegar; sulphuric acid is employed in the manufacture of a saccharine compound, which is used in the adulteration of cane sugar; and alum, plaster of Paris, and sulphate of copper are frequently resorted to for the purpose of whitening and increasing the sponginess of bad bread. All these adulterations are matters of very serious moment both to you and the public, and the discussion of them is, in my opinion, very properly suited to this course of lectures. I shall, therefore, direct your attention to them in a very pointed manner.

All the Vinegars of English commerce contain free sulphuric acid, inasmuch as the vinegar manufacturers are permitted by law to employ a certain portion, viz., the one-thousandth part by weight of oil of vitriol, for the purpose of checking the putrefaction to which the gluten of the liquid is subject; but, as Dr. Ure very properly remarks, "this is a miserable shift, or pretended necessity, in the present advanced state of organic chemistry. It offers, besides, an easy source of fraud, since neither the retailers nor consumers of the article are competent to distinguish how much of the sourness is derived from the mild fermented acid, and how much from the corrosive mineral. All the pickles in which our *bourgeoisie* so much delight are polluted by the same sophistication. Not long ago," continues Dr. Ure, "a sample of vinegar was submitted to me for examination, said to be that supplied by contract to the British Navy. I found it to contain little more than half the fair amount of *proof* vinegar, with much gluten, and a copious supplement of oil of vitriol." Here, also, is a sample of cheap vinegar, which I have just obtained from one of the retailers in this neighbourhood, and you will notice that it yields a copious precipitate with a soluble salt of baryta; it contains, in fact, as much as 0·65 per cent. of sulphuric acid, and a fluid ounce of it yields very nearly nine grains and a half of sulphate of baryta, in place of one grain and fourteen hundredths which are allowed by law.

On the Continent, also, manufacturers are accustomed to adulterate vinegar, and many varieties of low red wines, with alum or sulphuric acid; and the fraud has become so serious, that chemists have thought it necessary to inquire into the matter, in the hope of being able to point out a ready mode of detecting the imposition. To this end Orfila directs that the suspected liquid should be agitated with ether; and, after standing for a short time, the etherial solution is to be decanted and tested for free sulphuric acid. It does not appear, however, that this mode of proceeding is a very satisfactory one; for, as I have already informed you, upon the authority of Dr. Christison, ether will not remove sulphuric acid from an aqueous solution. Guibourt, in fact, has put this to the test of actual experiment in the case of one of the liquids in question, and he has drawn from Orfila an admission, that ether will only take up a trace of the poison. Lassaigne, also, states that, in an examination conducted by MM. Ossian Henri, Bayard, and himself it was not possible to separate, by the action of sulphuric ether, four or five-thousandths of sulphuric acid added to red wine, and, consequently, that this method of operating would not answer for the detection of the impurity.

In the London Pharmacopœa, it is directed that the quantity of sulphate of baryta precipitated from a fluid ounce of vinegar by the addition of a soluble salt of baryta should not exceed 1·14 grains. But this rule, however applicable it may be to the composition of malt vinegar, cannot be applied either to wines, or the vinegars obtained therefrom; for grape juice contains very variable proportions of alkaline and earthy sulphates,—salts which will be sure to vitiate the results of the inquiry. It is necessary, therefore, under these circumstances, to proceed in a different manner.

MM. Lassaigne, Ossian Henri, and Bayard, inform us that they have, after many failures, been enabled to decide on a re-action, which is so delicate, that it will discover the presence of a one thousandth and a half of free sulphuric acid in red wine. They say, that when a piece of paper which has been touched with pure wine is dried at a gentle heat, the spotted portion is unaltered; whereas, paper which has been moistened with wine, to which a very small quantity of sulphuric acid has been added, reddens, and becomes brittle and friable between the fingers, when slightly rubbed, before the white paper becomes at all coloured.

Pure wine, to which nothing has been added, leaves by spontaneous evaporation a violet blue spot; whereas, wine to which a very small quantity of sulphuric acid has been added, (two or three thousandths) gives by drying a rose-coloured spot.

On examining into the sensibility of this simple process, the authors found that they were enabled to detect, by its means, one thousandth of sulphuric acid in red wine.

The paper most proper for the experiment is common glazed paper, containing starch or fecula. This kind of paper is well known in commerce, and it is easy to discover it by the blue colour which it assumes when moistened with an aqueous solution of iodine.

Now, although this re-action is a very delicate one, yet I prefer to operate in the following manner. Take a given portion of the suspected fluid (wine or vinegar,) evaporate it in a water-bath until it acquires a syrupy consistency, then treat it with strong spirit of wine, filter it; and precipitate the sulphuric acid contained therein by means of chloride of barium and a little nitric acid. In the course of this operation the alcohol will take up the free sulphuric acid, and will leave the neutral sulphates untouched.

Another, but not equally successful mode of operating is the following. Take two equal portions of the suspected liquid. Precipitate the sulphuric acid contained in one of them, and weigh the product. Evaporate the other portion to dryness, ignite it, re-dissolve the residue in water, filter it, and precipitate as before. The weight of this product indicates the amount of combined sulphuric acid present, while the weight of the former represents the entire quantity of acid (free and combined) which existed in the liquid. Upon subtracting, therefore, the weight of the one from that of the other, we can easily determine how much sulphuric acid had been fraudulently added to the liquid.

Again: *Bread* is often adulterated with metallic and earthy sulphates for the purpose of making it look white and spongy. Upon the Continent, especially in the north of France and in Belgium, public attention has been long called to the fact, that bakers are accustomed to employ a solution of blue vitriol (sulphate of copper) for this purpose; and M. Kuhlmann, formerly Professor of Chemistry at Lille, has collected a great number of facts which bear upon this subject. They were published under the direction of the Central Council of Salubrity of the Department du Nord; and although I think it right to allude to them here, yet I shall postpone their consideration until we come to treat of the metal which constitutes the chief ingredient of the poison.

From Kuhlmann's researches it appears, that sulphate of copper exerts a very energetic and peculiar action on the fermentation of bread. He states, that the addition of one grain of this salt to three pounds of dough will cause it to rise to a much greater extent than it would otherwise do, and thereby make the bread look white and more vesicular.

Alum is known to operate upon dough in a similar manner; for "it keeps water and rises well," as bakers express it, and so enables them to set off a very inferior and otherwise unsaleable flour. In the "Encyclopædia Britannica," and in the Dictionaries published by Dr. Ure. I find the following statement:—

"In London, where the goodness of bread is estimated entirely by its whiteness, it is usual with those bakers who employ flour of an inferior quality, to add *as much* alum as common salt to the dough; or, in other words, the quantity of salt added is diminished one-half, and the deficiency supplied by an equal weight of alum. This improves the look of the bread very much, rendering it whiter and firmer." "Now," says Dr. Ure, "we may hence infer, that the full allowance here assigned of two and a quarter pounds of alum for every two pounds and a quarter of salt, will be adopted in converting a sack of flour into loaves. But as a sack of flour weighs 280 pounds, and furnishes, on an average, 80 quartern loaves, we have 2¼ pounds divided by 80,—that is, 197 grains as the quantity of alum present in a quartern loaf. And, as I need hardly tell you, it is a very serious thing for a gentleman or lady, of sedentary habits, or infirm constitution, to have the digestive process daily vitiated by damaged flour,

whitened with 197 grains of alum per quartern loaf. Acidity of stomach, indigestion, flatulence, headaches, palpitation, costiveness, and urinary calculus, may be the probable consequences of the habitual introduction of so much acidulous and acescent matter."

My own experience is quite confirmatory of another observation made by Dr. Ure, who says, "I have made many experiments on bread, and have found the proportion of alum very variable. Its quantity seems to be proportional to the badness of the flour; and hence, when the best flour is used, no alum need be introduced.

Plaster of Paris is another agent which is sometimes used for the sophistication of bad flour. I here show you a specimen of ship-biscuit, furnished by a cheap baker to a trading captain. It contains 5·5 per cent. of sulphate of lime, which has, doubtless, been introduced for the purpose of increasing the weight and improving the appearance of a bad article.

All these adulterations may be recognized by digesting the bread after it has become very stale, in distilled water, and testing the solution with nitric acid and baryta for sulphuric acid. Good bread scarcely affords a cloudiness with this re agent, and the precipitate so obtained is too small to be weighed. Again, the last-named adulteration may be discovered by igniting the bread and weighing the residue. Good flour or bread will not yield more than 2 per cent. of ash, the greater portion of which is soluble in about ten drops of water.

The last point to which I shall direct your attention before I leave this subject, is the fact, that cane sugars are frequently adulterated with a low kind of saccharine product, obtained by the action of dilute sulphuric acid on starch. This sugar, which is identical in composition with grape sugar, is recognized by its granular or powdery appearance. In fact, it does not possess a crystalline structure; and hence it is devoid of that sparkling character which is possessed by cane, maple, and beet-root sugars. I am not prepared to tell you that the substance in question is positively hurtful to the human body, but I am in a condition to say, that the purpose to which it is commonly applied is injurious to the fair dealer, and is a gross fraud upon the public. Several chemical reactions have, from time to time, been referred to as a means of distinguishing the presence of glucose in the sugars of commerce, but in my opinion there are but two of them which possess any practical value:—1st. It was noticed by Mr Moore, and his observation has been verified by Chevalier and others, that starch or granular sugar acquires a deep brown colour when it is boiled with liquor potassæ, a reaction which is not manifested by any other species of saccharine matter. To employ this test, therefore, you take about ten grains of the suspected sugar, and heat it in a drachm of liquor potassæ; if the liquid acquire a deep coffee brown colour, it indicates the presence of this adulterating agent.

The second re-action was first noticed by M. Trommer. It is dependent on the property which glucose or starch sugar has of reducing the hydrated oxide of copper; and, to make this re-action manifest, you proceed as follows:—Take about ten grains of the suspected sugar, and pour upon it a liquid consisting of six drops of a saturated solution of sulphate of copper, and ʒij. of liquor potassæ. Heat this mixture in a test tube; and, if granular or starch sugar be present, the solution will instantly acquire a bright orange colour at the point where the flame touches the tube; and gradually, as the heat is propagated through the liquor, the whole contents of the tube will change colour, and ultimately become of a deep brown red tint.

Starch sugar, a so, frequently contains a considerable portion of plaster of Paris, the residue of the materials employed in its manufacture; hence, if you digest such a sugar in strong alcohol, the saccharine matter will be taken up, and the sulphate of lime left behind in the form of a white powder.

By adopting one or other of these means you will have no difficulty in discovering the fraud in question.

In my next lecture I shall commence the subject of nitric acid.

ORIGINAL CONTRIBUTIONS.

OBSERVATIONS ON THE RECENT EPIDEMIC CHOLERA.

By GEO. ROSS, Esq.

[Late Medical Officer of the West London Union, Author of Lectures on the Asiatic Cholera, &c., "Medical Times."]

THE INFLUENCE OF LEVEL, VENTILATION, AND CONTAGION.

The largest number of cases of cholera during the recent visitation occurred in the low lying districts, and especially in the parishes on the banks of the river. In my lectures on the former epidemic, I demonstrated this fact in respect to that visitation, with, however, the qualification, that certain central districts exhibited as high a mortality as the water-side districts,—a result clearly owing to local insalubrities. I then showed the probability, that the statistics relating to the epidemic in Paris, published by M. Gendrin, who declared that the mortality in the respective districts from cholera, was in an exact ratio to their contiguity to the river, were incorrect, as they did not accord with our metropolitan experience. The Registrar-General acting for the Government, has done for this epidemic what I essayed to do for the last, and by pursuing a similar method, has arrived at similar conclusions. In all material points, the statistics published by the Registrar-General are corroborative of those antecedently published by me; and the conclusions I then formed may be considered as established.

Those courts, in my own neighbourhood, which were chiefly ravaged by the epidemic, were composed of badly constructed dwellings, and were insufficiently ventilated. Imperfect ventilation, more than any other cause, seemed to determine the activity of the disease. Black Horse court and Poppins' court, and the lower half of Farringdon street on the west side were particularly scourged. In that portion of Farringdon-street, consisting, at that time, of thirteen inhabited houses, sixteen deaths occurred, either immediately within the walls, or after removal, whilst only one death, so far as I know, happened on the eastern side of the street.

Now, these doomed houses in Farringdon-street are inhabited by respectable tradespeople, and are generally kept clean and wholesome, but they are unfortunately built back to back with Black Horse-alley, a very narrow and dirty court, which is again built back to back with Poppin's-court; consequently there is no thorough ventilation through the whole of this district.

After this locality Crown-court and Hanging Sword-alley were chiefly attacked, and these courts, also, are built back to back. There were several other courts and alleys of as humble and dirty a character, which nevertheless escaped the rigour of the epidemic,—chiefly, I apprehend, through enjoying a somewhat better ventilation.

The consideration of the diffusion of the epidemic in particular localities leads us forward to the subject of contagion as a means of propagating the disease. I doubt if this question admit of absolute proof one way or the other; and, although facts may be piled on facts, and argument succeed to argument, yet the means of forming the "experimentum crucis" may never be attained. The question will be settled rather by common consent as the result of general experience, and of the observation of the analogies of the disease with the phenomena of other admitted contagious diseases than by positive demonstration. The contagion of small pox was at first doubted or denied; it was then admitted as the result of experience, and subsequently it was demonstrated by the actual transference of the dis- [illegible] by inoculation. Now, with the exception of [illegible] 'oof of the contagion of [illegible] that can be adduced to prove the contagiousness of one disease that will not find its parallel in the history of the other; or, to take lower ground, the arguments employed to prove the communicability of measles, hooping-cough, or typhus fever, will equally apply to cholera; and either this is communicable, or they are not. Innumerable facts have already been cited by other writers to prove the communicability of cholera, and I have observed similar facts in my own practice; but these facts have been invariably met by the objection, that the person declared to have received the disease by contagion might have succumbed under the epidemic influence of the locality, and that there is no fact to prove that such was not the case. Granted: but does not this objection apply equally to measles or hooping-cough? What constitutes an epidemic influence? It is not necessary for our purpose to inquire into the origin of "first cases," because it is self-evident that a first case could not be derived by means of contagion; and there might be many such first cases having a sporadic origin. These prove nothing against the doctrine of contagion. We have to deal with cases in which the conditions necessary to contagion are present.

Given, then, the place and the patient, the question is, Was the disease acquired from the one or the other? In all other supposed contagious dis- [illegible] it is unhesitatingly referred to the patient; but in cholera it is assumed that the disease, migratory as it is known to be, must have visited the place as an epidemic, and that contagion is an impossibility. And this position is broadly asserted, even under circumstances where there are links of evidence tending to show that the disease was imported.

But if an epidemic influence must be assumed, then how many cases constitute the proof of it? Is one sufficient, or two, or three, or four? The Registrar-General informs us, that at Dunmow three deaths from Asiatic cholera had occurred. "A woman and her child, (6 years old,) came from West Ham, (where it was at that time very fatal,) on the evening of the 8th of September; about two hours after eating her supper, the child was attacked with severe and constant vomiting and purging; collapse took place the following morning, &c., and the child died on the evening of the 9th. The grandmother of the child, aged 62, was seized with diarrhœa, and, after three days' illness, applied for assistance, collapse having begun. She died on the morning of the 14th of September. The grandfather, aged 61, was attacked with severe vomiting and purging on the 20th; collapse ensued, and he died of consecutive fever. The mother and father of the child were also attacked, but recovered. "No other deaths," the Registrar reports, "from cholera have occurred as yet in this district." Are these cases all happening in one family a proof of an epidemic influence! If so, we must commence studying a new system of inductive inquiry.

To assume that the epidemic influence of the locality caused the disease and nothing else, is at least a *petitio principii*, and a very poor argument. Where is the proof? Nay, says the objector, but the possibility! Aye, the possibility.

Facts have been recorded to show, that nurses attending on cholera patients have, subsequently, suffered from the disease; that patients taken to distant localities have introduced the disease to the houses where they were domiciled; that the bed-clothes and body linen of cholera patients, carried away to be washed, have engendered the disease; but the objection has been pertinaciously offered, Who knows that the epidemic was not lurking in the neighbourhood before the arrival of the patient or the fomes? The facts are not conclusive, &c.

The argument of ignorance, as used against positive facts, ought not to be suffered to have much weight, for there can be no end of questioning if appeals to the unknown are to be arrayed against the known. In one house that I attended there were not less than seven deaths amongst the different families residing in it, whilst, in the next house, resembling it in every respect as regarded locality and sanitary condition, there was not one death. If such a circumstance had occurred in respect to scarlet fever or measles, we should have no difficulty in acknowledging the fact of communication by contagion. Although the case cited above was an extreme one, yet such was the rule; and, wherever one case of cholera occurred, I was very frequently

soon after called to another. Those persons nursing the sick were peculiarly liable to an attack.

I am not anxious to enumerate facts tending to prove the doctrine of contagion, because I must confess I could adduce no facts that even myself, in a sceptical mood, could not charge with suspicion, and because my chief object is, to exhibit the fallacy of the arguments that have been employed to refute it. A man is taken home from his work ill of cholera,—he dies; his wife, who nursed him, is also taken ill of the same disease, and, after her, two daughters who nursed her are stricken by the epidemic. It might be said, in explanation of these attacks, that the daughters inherited the idiosyncracy of the parents, but it cannot be assumed that the father and mother were equally predisposed by identity of temperament. Community of sanitary influences might be supposed to be a sufficient cause, or the epidemic atmospheric constitution; but this is, after all, an imposition on the judgment. Who has yet ascertained this special atmospheric poison? It is an assumption, and those who ridicule the doctrine of contagion have yet to prove that their own doctrines are exempt from error.

I have known a woman hired to nurse another, and commencing her duty in good health, eventually succumb to the disease. In this case the house was well ventilated, and she was supplied with every comfort. Very many instances, however, of the attendants on the sick taking the disease have occurred within my observation. In all these cases it may be objected that the disease was previously in the neighbourhood, and I admit it; but there are scores of well-authenticated cases of persons carrying the disease into unvisited neighbourhoods, and to all appearance communicating it to others. Such a case I have already referred to. Why should such evidence be cavalierly rejected in favour of a mere assumption?

Although I refrained from expressing an opinion upon the subject, in my lectures on the last epidemic, yet I had formed a strong conviction of the non-contagiousness of cholera, and it was only after many weeks' experience of the disease that I was led to change my opinion. I do not wish to contend about words, but, I am sure of this, that a person in attendance upon a patient labouring under cholera may receive the disease in consequence of such attendance, and through an influence exerted upon him by the morbid state of the patient. I do not presume to define this influence, or to settle whether it be by contact or inhalation,—whether by a gaseous poison acting upon the blood in the lungs, or by an effect otherwise produced. These are speculative questions awaiting facts for their solution, and I shall not touch them; but I have no doubt of the general truth of the communicability of cholera.

It is probable that cholera is contagious only in a diminished degree, as compared with the exanthemata, or even with typhus,—the contagiousness of which disease is a matter of dispute,—and that a free aeration of the apartment would very much abate the liability. I apprehend, that, with an ample supply of fresh air, the deleterious agent would be too much diluted to exert its maleficence on the animal economy, and thus the communicability of cholera can only be tested in a locality already acknowledged to be favourable to its development. If, however, cholera depend upon a specific poison, its communicability is highly probable.

In my own case, I was, in two or three instances, sensible of a poisonous influence having been exerted upon me whilst standing at the bedside of a patient, and was obliged to fly to the door to avoid the vomiting which threatened. I was generally affected with diarrhœa after such occurrences, and omitted to visit the severer cases for a few days. It is right to observe, that I had disordered bowels, nausea, &c., for six weeks during the prevalence of the epidemic, and was, therefore, more predisposed than usual to receive a malign influence. The gentlemen who assisted me, however, were sensible of [illegible] deleterious agency.

[illegible]lera is, apparently, propagated both by epidemic influence and by personal communication, though what share each cause may have in its diffusion it is not easy to determine.

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.

It is proposed, in these Reports, to give an account of some of the more important cases which have been recently discharged from, or may be still under treatment in, the surgical wards of the hospital. Attention will, especially, be directed to the interesting operations which are usually performed on the Saturday; and these will, occasionally, be illustrated by drawings. The Reports will be made as brief as possible, consistently with the design in view, namely, to furnish a general summary of the surgical news of the week, rather than a heavy detail of cases.

NECROSIS OF THE WHOLE OF THE LOWER JAW,

IN CONSEQUENCE OF LONG CONTINUED EXPOSURE TO THE FUMES OF PHOSPHORUS ACID VAPOUR, IN THE MANUFACTURE OF LUCIFER MATCHES.

The following very interesting case has attracted considerable notice for several months, and is now about to leave the hospital:—

Thomas Beckingham, aged 22, was admitted into Darker ward, under the care of Mr. Stanley, in the latter part of last January. At that time he had well marked symptoms of necrosis of the left half of the lower jaw. There was great swelling of the soft parts on the left side of the face, with one or two fistulous holes through which the probe passed to dead bone. He gave the following history of himself:—About six years ago, being then in excellent health, he became a workman in a lucifer-match manufactory. His particular business was to mix the phosphorus with resin and chlorate of potash in a vessel placed over boiling water, during which process the phosphorus evolves copious fumes. After being employed in this occupation for about two years and a half, his health began to suffer. The first symptoms of indisposition were occasional attacks of griping pain in the abdomen, followed by diarrhœa. Such attacks, he says, are by no means of infrequent occurrence, in other men engaged in the same work. In the course of a few months, he began to suffer from toothache, and swelling of the gums on the left side of the lower jaw. He always suffered more when at his work, but felt relieved when he left the factory at night. The symptoms gradually increased in severity, till at length, scarcely ever free from pain, and in a sickly-looking, deplorable condition, he sought relief at the Hospital.

Soon after his admission into the Hospital (in January last), the teeth dropped out one after the other from the left half of the lower jaw, and, about the middle of the summer, this half had perished, and was sufficiently loose to be removed. Subsequently, the remaining half of the jaw became affected with necrosis, in a manner precisely similar to the other, and has been removed. Thus, the whole of this man's lower jaw (with the exception of one condyle which was absorbed), may be seen in the museum of the Hospital. Those who are curious enough to inspect it, may observe that the necrosed bone is partially covered by irregular masses of newly-formed osseous substance, in colour and texture not unlike pumice-stone.

Considering the loss of so large a portion of the bony framework of the face, it might naturally be imagined, that the countenance of the individual would be greatly altered. But this is so far from being the case, that, on mere superficial observation, one would hardly recognise anything unusual about it. How can this singular circumstance be accounted for? Certainly not by the formation of any new bone, but rather by the formation of a kind of ring of firm fibrous tissue, which occupies the place of the lower jaw, and serves to support the soft parts. This ring can be felt distinctly at the chin, and inside the mouth, and is, moreover, so hard and solid, that one would really suppose it were bone. At all events, it is a beautiful provision made to supply the loss of the old bone; for it not only preserves the contour of the face, but also serves as a fixed point for the action of the muscles concerned in mastication, deglutition, and in the movements of the tongue. Thus, the patient is enabled to open and shut his mouth, and to put out and retract his tongue as before. With regard to the mastication of his food, this, of course, is a matter of some difficulty, but, even in this respect, he manages tolerably well; so that, upon the whole, it may fairly be said, that our patient is not, even with the loss of the entire jaw, worse off than many an elderly person who has lost his teeth.

For the history of the case we are indebted to Mr. Thornton, one of Mr. Stanley's dressers.

Other cases of disease in the lower jaw, in individuals engaged in the manufacture of lucifer matches, have been, from time to time, in St. Bartholomew's Hospital. But they are much more prevalent in the London Hospital, in consequence of the number of lucifer-match manufactories in that neighbourhood. In the manufacture of these matches, it appears that a large quantity of phosphorous acid vapour is given off, especially in the drying rooms, and that persons employed in these rooms have been attacked with necrosis of portions of the lower or upper jaw. Mr. Stanley, who enters at length into this subject in his work on diseases of the bones, considers, that long exposure to the fumes of phosphorous acid gives rise to inflammation of the periosteum of the jaw, and thus produces the death of more or less of the bone. The first indication of the disease is toothache; subsequently the teeth drop out; then the affected portion of the jaw dies, producing abscess and fistulous passages in the soft parts, with extremely fetid discharge. Under such circumstances no reproduction of the bone ensues. When the disease has once set in, nothing can stop its progress. All that we can do is, to support the patient during the tedious and debilitating process of separation of the necrosed bone, and to remove it as soon as it is sufficiently loose. Fortunately, however, a discovery has lately been made, which may prevent, for the future, the occurrence of this formidable affection. Mr. Stanley mentioned this discovery to the students in the wards of the Hospital. It appears, that if plates or saucers, filled with turpentine, be placed in sufficient numbers in the drying rooms, the noxious vapour of the phosphorus will be taken up and dissolved by this fluid, so that the air of the rooms may be breathed with impunity.

In connexion with this subject, it may not be out of place to mention a somewhat analogous disease in the bones produced by arsenic. There is an excellent example of this in the museum of St. Bartholomew's Hospital. (First series, sub-series A., No. 156.) We may there see several bones from cows fed in meadows near Swansea, in the neighbourhood of which there are copper works. In melting the copper ore, fumes of arsenic are so copiously disengaged that no animal or vegetable can long live within the sphere of their influence. The animals become disabled from disease in their bones, which become enlarged, porous, and spongy, and covered by unhealthy osseous deposits. It is probable that, the arsenic, contaminating both the air and their food, excites inflammation of the periosteum and bones, of a character resembling that which occurs in the jaws of persons employed in making lucifer-matches.

NECROSIS OF AN OSSEOUS GROWTH PROJECTING INTO THE ANTRUM OF THE UPPER JAW.

For the report of the following remarkable case, which is still in Darker Ward, under the care of Mr. Stanley, we are indebted to Mr. Harry Thorold, one of the dressers:—

George Alworthy, aged 34, a well-built, healthy-looking man, was admitted into the Hospital, during the middle of last summer, on account of a disease of the right upper jaw. There was an obvious enlargement of the nasal portion of the bone, together with a conspicuous bulging of the front wall of the antrum; the arch of the hard palate on the corresponding side was depressed, and the respiration through the nostril of the affected side was completely impeded. So far the disease looked like an enlargement of the antrum, by the projection of

some morbid growth into its cavity. It was probable, however, that more or less of the alveolar portion of the bone had perished, because the second incisor, the canine, and both bicuspid teeth were loose, the corresponding gums pulpy and swollen, and presenting two or three suppurating openings, through which the probe passed down to bare bone. The man stated, that his disease commenced about three years ago, when he first noticed a hard prominence by the side of the nose, for which he could not in any way account. For a long period this bulging did not increase, nor occasion any pain or uneasiness. But, about May last, he observed that his face began to swell, and this was soon followed by painful swelling of the gums, which induced him to apply for relief at the Hospital.

Such being the symptoms, the question arose, whether the case were one of simple necrosis of a portion of the upper jaw, with an enlargement of its nasal process, or whether this enlargement were but part of a general osseous growth, with a supervening necrosis of the alveolar border of the jaw. Under this doubt it was agreed to defer any operative proceeding. Our patient had been in the Hospital about two months, when a large abscess formed in the cheek just below the orbit, and, when this was opened, a quantity of fetid pus was evacuated, and a considerable portion of the jaw was felt bare and crumbling. Soon after this occurrence, it became evident that the dead bone was moveable, and Mr. Stanley decided on removing it. Without much difficulty the bone was removed with the forceps, and with it, to the surprise of all present, there came away a ball of necrosed bone which filled the antrum. When this bony mass was removed, there remained a large cavity, communicating widely with the nose and the mouth, with its walls covered by granulations. The growth itself consisted of a mass of firm and finely cancellous bone, of nearly spherical form, and about one inch in diameter. The case is now proceeding very favourably; granulations are rapidly filling the cavity, and the patient will soon be in a condition to leave the Hospital.

The case, therefore, has proved to be one of rather rare occurrence, namely, the spontaneous separation of an osseous growth from its surrounding connexions. Baron Boyer makes mention of two instances of the kind. (a) Another case has been recorded by Mr. Hilton, in which a large ivory exostosis separated spontaneously from the bones of the face. (b)

RESTORATION OF THE LOWER LIP AFTER THE EXTIRPATION OF AN EXTENSIVE LIP CANCER.

This operation has recently been performed by Mr. Skey with success, and in a manner which is rather novel. The patient, a man beyond the middle period of life, had allowed a cancerous ulcer of the lip to extend so far, that it had involved nearly the whole of the lower lip down to the chin. Besides this, there was a small indurated knot in the right cheek, and a small glandular enlargement a little below the angle of the jaw. These were both of them removed. The cancerous ulceration was then carefully extirpated by two semicircular incisions, commencing at the corners of the mouth and meeting at the chin. A portion of skin, of suitable form and size, was then dissected from the front of the neck, immediately below the jaw, and then raised up so as to fit into the place of the removed lip. The vitality of this flap of skin was maintained by two bridle-like slips of integument, cut obliquely, one on either side, out of the lower part of the cheek. These slips not only supplied the flap of skin with blood, but also permitted it to be raised into its new position with greater facility. The parts were then properly brought together by sutures. Everything has proceeded favourably. The wounds have united by the first intention, and the patient has just left the Hospital, quite satisfied with the result of the operation.

(a) Traité des Maladies Chirurgicales, Tome III. p. 554.

(b) Guy's Hospital Reports, Sept., 1836.

The restoration of the lip after the removal of a labial cancer, has been repeatedly performed by Dieffenbach. (a) But his operation consisted in bringing together the edges of the wound, after having loosened the skin on either side from the ramus of the jaw. He was also in the habit of using needles instead of sutures.

IMPORTANT VARIETY IN THE COURSE OF THE INTERNAL PUDIC ARTERIES.

In demonstrating the anatomy of the perineum in an adult male subject, Mr. Coote met with the following very important variety in the course of the internal pudic on both sides. After re-entering the pelvis through the lesser ischiatic knotch, the artery, instead of ascending, as usual, behind the ramus of the ischium and the pubes, passed on by the side of the rectum towards the so-called triangular ligament, and then gave off its three terminal branches, namely, one to the bulb of the urethra, another to the crus penis, and lastly, the dorsal artery of the penis. Had lithotomy been performed upon this subject, the pudic artery would have been unavoidably divided; and it might possibly have been cut through in laying open a fistula in ano. During the course of the last winter a similar variety in the course of this artery was observed. Though it is comparatively a rare occurrence to meet with such variety in the course of the main artery, yet is it by no means uncommon to find that one of its chief branches, namely, the artery of the bulb, arises lower down, (that is, nearer to the anus,) than usual, and then runs transversely across the perineum to the bulb; consequently, it is directly in the way of the incision in lithotomy. There is a preparation in the Museum which displays this point remarkably well. In the body already alluded to, several other unimportant anatomical varieties were also observed. Perhaps the most curious was the absence of both subclavius muscles.

In our report of next week, we propose to give the particulars of a case of compound dislocation of the ankle, and also a case of compound fracture of the leg, both of which cases have required amputation. An account, illustrated by a diagram, will also be given of an operation performed on Saturday by Mr. Lloyd, for the restoration of a lower eyelid, partially destroyed by ulceration.

KING'S COLLEGE HOSPITAL.

Reported by DUNCAN FERGUSON, Esq., late Physicians' Assistant King's College Hospital.

SYPHILITIC PSORIASIS AND CORYZA.

1.—Frances Kelly, aged 5 months, was brought as an out-patient under Dr. A. Farre, July 27. The child was born at full time; was of the usual size; had no cutaneous eruption; took the breast well; was troubled with what the mother called "the snuffles."

Father's age is 25, a healthy-looking man, has had syphilis before and after marriage. Mother's age is 25, healthy; nutrition good; has not any sore on genitals, but, at present, has sore throat; married eighteen months.

At present, the child is smaller than usual at five months and has lost flesh lately. The snivelling is severe; the nose is tender when touched, and the bridge concave; the Schneiderian membrane is inflamed, and secretes a muco purulent discharge, which concretes and occludes the nostrils. Patches of psoriasis are seen on the chin, cheeks, eyelids (which are deprived of hair), neck, chest, and arms. They are very plentiful around the anus, pudendum, and nates.

Tongue coated, bowels relaxed, restless at night, skin hot and dry.

℞ Hydrarg. cum cretâ gr. j., pulv. cinnam. co. gr. ij., o. n. s.

℞ Ung. hyd. ammon. chl., bis die appl.

℞ Lot. plumbi, sæpe utend.

℞ Mist. ammon. cit. ℥ij.; vin. ant. pot. tart. ʒj.; M. Capt. ʒj.; 4tâ horâ.

(a) Chir. Erfahr. über die Wiederherstellung Zerstorter Theilé. Berlin, 1834.

August 1.—The child has much improved; the eruption is much less; appetite good; coryza continues.

Sept. 7.—Convalescent. (Omitti mist. and ung. Rep. pulv.)

2.—William Goddard, aged 11 weeks, was brought to Dr. A. Farre; is a first child born at full time.

Father's age is 26; has not had syphilis since marriage, which took place eighteen months ago; health good. Mother has never had syphilis; nutrition good.

When the child was born he had an eruption on the skin which soon disappeared. At present, the face is almost covered with patches of psoriasis; they are also seen on the trunk and extremities, around the anus and over the scrotum. The angles of the mouth and nose are fissured. Has had coryza since three weeks old, and the discharge is now very profuse. Appetite very good, bowels regular, and, in other respects, pretty well.

The treatment, in this case, consisted in the exhibition of small doses of grey powder at night, white precipitate ointment over the patches, and lead lotion constantly applied over the nose, and now and then injected up the nostrils.

Sept. 21.—The child is much better. The psoriasis is disappearing; the fissures have healed.

Oct. 15.—Convalescent.

3.—George Wasmith, aged 4 months, was brought to Dr. A. Farre, July 1. Father is a healthy-looking man; had syphilis before marriage. Mother is a delicate, anæmic-looking woman; has not had syphilis. She has had five miscarriages early in gestation, and one child besides the patient, who is 9 years old, and has always had good health; married twelve years.

The patient was born at full time, and was thought to be a fine healthy child. At present he is much wasted, and has a sickly, blanched appearance.

The body is covered with psoriasis, and he is much troubled with coryza. There is thickening of the periosteum of the bones of the left forearm.

The same remedies were adopted; the child, however, was under treatment for two or three months, when he was discharged cured.

4.—Edward Cutforth, aged nine weeks, was brought to Dr. A. Farre, July 18; mother's age is 24; has been married two years; enjoys good health; never had syphilis; has had two miscarriages. Father's age is 26; had not had syphilis since his marriage.

The child is small for its age, is much troubled with snivelling, which commenced at birth, and has continued ever since. The mother describes the child as being "like a spotted leopard;" patches of psoriasis are extensively diffused over the body.

Sept. 30.—The child has perfectly recovered.

5.—Mary Ann Hickman, age nine weeks, was brought as an out patient under Dr. A. Farre, Oct. 3.

The mother's age is twenty, when pregnant three months with the present child, her husband gave her the venereal disease, for which she was under treatment six weeks; seems now in good health.

The child, when born, was in good health. At present it is delicate looking; has severe coryza, and the body is covered with psoriasis.

Treatment as in the former cases.

Nov. 4.—The child is now convalescent.

Remarks.—Cases like the above are very common in the out-patient room at the King's College Hospital, and are generally very amenable to the treatment adopted. Now and then, however, in spite of all remedies, the child loses flesh, becomes more fretful, irritable, and frightfully emaciated; the bones of the nose become diseased, and ozæna is the consequence. The child, under these unfavourable circumstances, very soon dies.

The venereal poison seems, from the cases I have related, to affect the fœtus in utero, when either parent has a syphilitic taint. In most of the cases I have investigated I find the mothers are subject to continual miscarriages, no doubt from the diseased condition of the fœtus. It is remarkable how one child escapes, and all the others become more

or less affected. In the case of Wasmith, the wife had never any syphilitic symptoms, nor had the husband for twelve years, and still the poison tainted, during and after that time, all the offspring with a single exception.

The symptoms are very uniform. The child is born in apparently good health, with the exception of a slight cold, which, however, generally persists. This coryza may not appear for a few weeks, and is soon succeeded by a scaly eruption on different parts of the face, and around the anus and genitals. The lips and angles of the nose crack. The nose is tender to the touch, and always unusually concave. The mucous membrane is red and inflamed, and a copious discharge runs from it, which, if not constantly wiped off, blocks up the nostrils, and adds to the child's distress. Now and then there is purulent ophthalmia and cough. The child is generally restless and fretful, sleeps badly at night, unless dosed with Godfrey's cordial; loses flesh, becomes shrivelled and dies, unless some efficient treatment be adopted to stay the progress of the malady. In all such cases *mercury is the remedy.*

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

In alluding to the opening of the Medical Session here I should have mentioned, that two of the Sessional Prizes were awarded to foreigners. Mr. Robert Hamilton, of Cork, obtained the prize of the "Ecole Pratique," and one of the Egyptian students carried off that of the School of Pharmacy. Nothing is more calculated to encourage scientific research or the acquirement of sound knowledge, than this liberality, which throws open the contest for honours to the whole world.

At the recent distribution of rewards connected with the National Exhibition, only two individuals, —and these but remotely connected with Medicine,—received the Cross of the Legion of Honour. They were the Messrs. Kestner and Lacroix, manufacturers of chemical products at Thann and Chauny. Charriere and Samson, the surgical instrument makers, were decorated, if I remember right, after the former exhibition, in 1844. It is astonishing what energy and perseverance are engendered by the hope of obtaining this scrap of red ribbon; yet, like all other good institutions, it is sadly abused. Our President, for example, bedecks himself with the blue sash of the grand-cross wherever he goes, though everybody knows that he got it while in swaddling clothes; and many a medical man here wears the distinction with anything but honour to himself, because it was obtained by intrigue, not won by merit. It was curious to observe how all these false colours disappeared after the Revolution of February.

The Academy of Medicine has been occupied for the last three meetings by an important discussion on engorgements and deviations of the uterus. All the principal members of the Academy took part in this interesting debate, an analysis of which I shall not fail to forward you as soon as it shall be completed.

From the Institute we have little worthy of notice, except a report from M. Pagen on a new mode of preserving milk, which appears to be completely successful. The mode is simple enough, and consists merely in evaporating down the milk to a certain degree of consistency. It is indispensable to operate on milk of the best quality, and the quantity operated on should, as nearly as possible, be drawn at the same time, in order to avoid the changes produced by the atmosphere. From 75 to 80 scruples of sugar is mixed with each quart of milk, and the fluid then evaporated in very flat pans by means of steam, which circulates in a [illegible] envelope. The milk is never raised above [illegible]ng point, and the evaporation is aided by [illegible] of the mass. When reduced to two-[illegible]ths of its original bulk, the mass is placed in tin [illegible]s, which are hermetically sealed. M. Pagen and [illegible] Commission have tried this preserved milk in a variety of ways, and found that it answers the object perfectly. When diluted with a certain quantity of water, it is difficult to distinguish it from common milk.

ARTERIAL VARIX OF THE HEAD.

M. Maissonneuve related an interesting case of this kind at a recent meeting of the Surgical Society. A young female had received a blow on the right temple, which was followed, in about fifteen days, by a small tumour simulating aneurism. Compression was first tried, but failed. The tumour continued to increase, whereon M. Maissonneuve proceeded to take up the external carotid artery. This operation failed likewise. The internal carotid was next tied, and then the common carotid, in consequence of persistence of the hæmorrhage. This latter operation was immediately followed by hemiplegia of the left side of the face, which soon became complete, and terminated in death. On examining the body, a considerable portion of the right hemisphere of the brain was found softened, almost gangrenous.

The result of this case would appear to confirm the opinion of many surgeons that ligature of the primary carotid exercises no influence on varicose aneurism of the branches. But M. Robert called the attention of the Society to a case which demonstrated the contrary. It was the well-known case of a man on whom Dupuytren operated in 1819 for an erectile tumour behind the ear. Dupuytren took up the primary carotid and announced the patient as cured; but this was not quite true. The man was relieved, not cured. M. Robert saw him in 1829, and a short time ago also. He had had secondary hæmorrhage only three times since the operation, and the tumour appeared to be stationary. In 1846 an analogous case, followed by similar results, presented itself in the practice of M. Robert. Ligature of the carotid artery, not only suspended the hæmorrhage, but arrested the growth of the tumour. M. Robert therefore expressed his opinion, that extirpation of the tumour, as practised by many foreign surgeons, should be rejected.

It may be observed here, that M. Robert appears to have confounded together aneurismal varix and erectile tumour of the scalp, two diseases which may reasonably be distinguished from one another. The erectile tumour may be cured by ligature of the carotid; it has been cured by vaccination and many other modes of treatment; but it admits of doubt whether aneurismal varix can be cured by any other treatment than ablation of the tumour. This is the opinion of Mayo, Johnson, and many other surgeons of eminence. Besides ligature of the primary carotid is not so grave an operation as one might conclude anatomically. Norris has collected 140 cases, of which only 48 proved fatal. On the other hand, of 31 cases in which the primary carotid was tied for erectile tumour, 18 were cured, 8 ended fatally, and 5 were partially cured.

TREATMENT OF CROUP.

A new mode of treating this formidable disease —new at least in France—has been proposed by M. Miguel, and, it is said, tried with much success at the children's hospital, by MM. Trousseau, Blache, and Guersant. The treatment consists in administering large doses of calomel alternately with alum. M. Miguel gives every two hours and alternately 2 grains of calomel and 2 grains of alum. He thus produces rapidly mercurial stomatitis, which, it is said, appears to act as a powerful derivative on the original inflammation. The quantities of calomel and alum are varied according to the nature of the case, age, of the patient, &c., and in all the diphtheritic inflammation was remarkably modified. Thus, in one case, where the child appeared on the point of suffocation, and tracheotomy was about to be performed, M. Guersant administered 24 grains of calomel, and the same quantity of alum within the twelve hours. At this period the child appeared much relieved; salivation set in on the second day, and the child is now well. The only inconvenience of the treatment is that arising from rapid salivation. This is occasionally severe; but in so destructive a complaint as croup extreme remedies must be resorted to.

CURE OF CANCER.

Some curious experiments are now going on here under the superintendence of the Medical Society, and relative to Dr. Tanchou, who for many years has professed to cure cancer and several other intractable diseases.

On the 8th of March last Dr. Tanchou presented two patients to the Society, and requested the members to examine them. They did so, but strange to say, no two members could agree as to the real nature of the disease; nor would Dr. Tanchou, himself, undertake to pronounce a diagnosis. He merely affirmed, that they were cases of a "mauvaise nature." However this may be, the Doctor proceeded to treat the patients after his own fashion, and again presented them to the Society on the 5th ult. One of the patients had an open sore on the skin, which some said, was cancer, others lupus. The second patient laboured beyond all doubt under open cancer of the mammæ, and was, moreover, in a very bad state of health. Dr. Tanchou brought back the first patient cured. As to the second one, the ulcer of the breast was nearly healed; the cancerous diathesis had disappeared, and the patient had become fat. These were incontestible facts, and it may be worth while to relate how such results were obtained, although the worthy practitioner's treatment smells strongly of the charlatan. The treatment of the lupus patient lasted three months and a-half. It consisted in a substantial diet and frequent exercise in the open air. These were aided by a great variety of remedial means; first, tincture of iodine, then Fowler's solution, and then arsenic and iodine alternately. The sore was occasionally washed with tar-water, tincture of iodine, decoction of poppies, &c., and finally cauterized with nitrate of silver, creasote, and iodine. The cicatrix is now sound and healthy-looking.

The treatment of the second case was conducted on the same principles, but only gave rise to considerable amelioration. Even this, however, may be regarded as a progress, insomuch as the majority of the members of the Society had pronounced both cases absolutely incurable when first submitted to them.

ANOMALY OF THE CERVICAL VERTEBRÆ.

M. Dubreil, Professor of Anatomy at the University of Montpellier, relates a very rare case of anomaly of the cervical vertebræ. It consists in the existence of a supernumerary vertebra, and occurred in the person of a Swiss drum major, whom M. Dubreil had often remarked during his life time, on account of his extraordinary stature. A careful examination of the skeleton leads the author to conclude, that the anomaly consists in a duplication of the sixth vertebra of the neck. M. Geoffroy St. Hilaire never observed a case of this kind, and it appears the only one to be found in the annals of Medicine. I remember, however, when a student at Edinburgh, that a well known member of the Medical Society, remarkable for his height, was said to possess a similar deformity.

GERMANY.

[From our own Correspondent.]

GERMAN MEDICAL JOURNALS.

The convulsions which the length and breadth of Germany have lately undergone seem to have affected the progress of medical science much less than they have the political rights and relations of its professors. The four-and-twenty German Universities are in full operation, and redolent with spirit and with life; and if revolutions have not added to the stores of medical science, they have certainly not lessened the love of its students, or impeded the progress of its cultivation. After all that has been written about the stagnation of literature, and the impediments which the troubles of the times have thrown in its way, your readers will scarcely believe that Germany has still sixty principal medical periodicals, which fill a yearly mass of 3500 sheets—56,000 pages! The annual subscription to which amounts to 250 thalers, or about 37*l.* 10*s.* English.

Almost every branch of medical science has several publications devoted to its interests; but, strange to say, there is no journal that devotes itself exclusively to any of the large German Universities or Hospitals. The "Charité" at Berlin attempted to establish an organ of its own, but the idea met with little encouragement, and was abandoned.

CHOLERA COMMISSIONS.

The Bavarian Government has lately established a Commission, consisting of physicians and chemists, to inquire into the nature of cholera, and particularly as regards its connexion with atmospheric and telluric influences, electricity, magnetism, &c. Von Walther, the well-known Professor of Surgery in Munich, is the President.

ICHTHYOSIS CONGENITA.

We have a specimen of this rare disease at present in one of the Berlin Hospitals, in which no part of the body is free from the complaint, except the inguinal regions. The patient is a young child, who is otherwise in good health.

SYPHILIS AND MISRULE.

Syphilis and misrule would seem to advance together. Since the good-will and pleasure of the State decreed that brothels should be no longer licensed, and that the visitation and examination of prostitutes should cease in Berlin, syphilis has increased to a fearful extent. In 1845, when the laws regarding prostitutes were repealed, the number of patients treated for syphilis in "La Charité" amounted to 1135; in 1846, the numbers were 1310; in 1847, 1655; in 1848, 1814; and in the present year, it is said the returns will show an increase of 60 *per cent!*

SCOTLAND.

[From our Edinburgh Correspondent.]

Last week the winter session in the Edinburgh Medical School commenced. There is a good show of students. Edinburgh is again rising to the position it formerly held in medical education, the period of greatest depression being already past some years ago. For three or four sessions, notwithstanding that there have been seasons of almost unexampled pecuniary distress in the country, the number of matriculations in the medical department of the University has been progressively increasing. It is gratifying to think, that among the causes contributing to this return of prosperity, not the least is the present efficiency of the Medical Faculty of the University; and a like efficiency marks the extra-academical branch of the Medical School. In the University, to the names of Alison, Christison, Syme, Ballingall, and Trail, who represent the older part of the Medical Faculty, are now to be added those of Simpson, Miller, Gregory, Goodsir, Bennett, and Balfour. Since Mr. Goodsir's appointment, nearly for the first time in the memory of the present generation of medical men, the University of Edinburgh has enjoyed the benefit of an efficient Professor in the important department of Anatomy. And beyond all doubt it was the failure in Anatomy by the conjoined effect of the inactivity of the Professor, and the extreme scarcity of subjects, before the era of the Anatomy Act, that first diverted the current of medical students from Edinburgh. The facility of access to the Continental schools concurred with the decay of Anatomy in the University to bring down Edinburgh from the pre-eminence which it had so long enjoyed. Now, by a singular coincidence, these several causes of this decline have nearly at once become inoperative, for Mr. Goodsir is all that can be desired in a Professor, the supply of subjects is abundant, and the Continental schools are confessedly in a very unsettled state. As to the other departments of medicine, they never were on a more satisfactory footing. The Extra-academical School, too, is making vigorous efforts to maintain an honourable rivalry with the University. The new apartments close to the College of Surgeons, in Nicolson-street, for the accommodation of the chief part of this School, were opened last week. The arrangements in every part of the house are excellent. An able opening lecture was delivered by Dr. Alexander Wood to a crowded auditory. In this the example of the Principal in the University was followed, who now gives an annual lecture to the students at large on the first day of the session.

Besides the bustle consequent on the opening of the medical courses, other causes of excitement were in operation last week among our Professional brethren. Of these two deserve to be noticed, namely, an entertainment given by the College of Surgeons, and a proposal made by the Medical Faculty of the University to the managers of the Infirmary, to put the Clinical courses on an entirely new footing. The entertainment given by the College of Surgeons was on the occasion of Mr. Syme's election to the President's chair. It must be very gratifying to Mr. Syme, so soon after his return to Edinburgh, that the choice of him for the chair was unanimous. The entertainment was happily managed. It was in the evening, and took place in the hall of the College. It was numerously attended by the Fellows of the College; and among the guests were the Medical Professors of the University, many Fellows of the College of Physicians, and Medical officers of the public service on duty in the Castle and at Piershill. Mr. Syme made an excellent Chairman, and every one departed well pleased with the convivial amusements of the evening, and the sentiments expressed in the short speeches with which the toasts were prefaced and responded to.

The proposal for an alteration in the University clinical department of the Royal Infirmary has not yet been made public; but the snatches of it which have transpired have created no small excitement among certain parties whose interests are likely to be more or less affected, if some parts of the alleged proposal be carried into effect. As far as can be judged at present, the plan proposed by the Medical Faculty is not objectionable in itself, having for its effect simply to give greater facilities to the Professors of the University for clinical teaching. The objections arise out of its expected interference with other interests than those of the Infirmary itself. It may be regarded as a plan alternative with another project of the same body formerly announced in the *Medical Times* as in contemplation, namely, the establishment of a separate Faculty or University Hospital. This project, we may presume, they abandon, if their new proposal is acceded to by the managers. They are said, then, to ask in the first place, that 150 beds be placed at their disposal for clinical teaching in the two departments of medicine and surgery. This demand can create little difficulty, as the Clinical Professors can already command, by the present arrangements, within a small fraction of that number. Next, they ask that a ward should be set apart for uterine diseases, under the charge of the Professor of Midwifery, and a male ward for skin diseases. To the demand for these two wards no material objection can arise. Again, they ask for a resident clinical clerk, or superintendent of the clinical wards. This, we understand, has been already granted. Another demand is for the choice of patients out of the waiting-rooms, on four days out of the seven days of each week. As to this demand probably little difficulty will arise, since this extension of choice does not exceed one day more in the fortnight than the Clinical Professors are entitled to at present. Another demand is for an out-door relief of patients, to be taken charge of by the Clinical Professors alternately, with the ordinary Physicians of the house. Such an arrangement would probably extend the means of clinical instruction, both in the University and in the extra Academical School. With the exception of some minor points, these are understood to be all the demands applicable to the purely medical department of the Infirmary. In the surgical department at present the Professor of Clinical Surgery has about sixty beds, and the Professor of Systematic Surgery, as one of the acting surgeons of the Infirmary, has about twenty beds. The new scheme seeks, after a time, to diminish the number of beds held by the Professor of Clinical Surgery, and to give twenty beds permanently to the Professor of Systematic Surgery, after his period of service as an acting surgeon has expired; it moreover asks two small wards for male and female syphilitic patients; also a few beds for eye diseases, to be placed under the charge of the Professor of Anatomy. Nothing can seem less objectionable than these demands, there being but a few beds asked for the University Clinical School beyond what it is at present entitled to. But as Edinburgh has but one great hospital, there is but one field in which, in particular, surgical operators can acquire the confidence of the public. At present no more than four years' active duty is allowed to any one in the surgical wards of the Infirmary, with the single exception of the Professor of Clinical Surgery, who alone is a life surgeon of the Institution. But the arrangement proposed makes two additional life-surgeons, namely, the Professor of Systematic Surgery and the Professor of Anatomy. This the Fellows of the College of Surgeons are inclined to regard as equivalent to establishing a monopoly of the pure surgical practice in these Professors of the University. Hence, no doubt much opposition will be offered to the new scheme, unless some plan can be fallen on by which this objection can be neutralised.

The only kind of compromise that seems available to reconcile the contending interests in this case, is to hold out some sort of compensation to those Fellows of the College of Surgeons, who, by their special turn for surgery, feel themselves entitled to look forward to acquiring the confidence of the public of Edinburgh in pure surgery and as surgical operators. For example, the College of Surgeons might be allowed the privilege of recommending to the Managers a Fellow of their body, to be appointed senior acting surgeon for some such period as ten years, stipulation being made that the candidate should be of a proper age, say between thirty-five and forty-five, and that he had served previously as acting surgeon in the Infirmary for the period of four years, as fixed at present; and there might be a like arrangement for the recommendation of an ophthalmic surgeon, under appropriate regulations for a similar term of years. These should be extra appointments, so that there might still remain two acting surgeons and two assisting surgeons, under the same regulations as exist at present. All that is required for the working of such a double scheme as is here supposed, is a small increase of surgical patients, and that may be looked forward to in the natural progress of things. One thing, the Managers of the Infirmary must take care to secure, in the event of the University scheme, or any part of it being carried into effect, namely, that such a control be left in their hands, as may enforce the efficient performance of the hospital duties undertaken by the Professors. For it must not be assumed, that the same energetic activity by which the University is distinguished at present, will remain unabated in all time to come.

SELECTIONS FROM FOREIGN JOURNALS.

CHOLERA IN THE HORSE.

A communication has been addressed to the editor of *L'Union Médicale*, on Cholera in Horses, by M. Liegey, of Rambervilliers. It is stated, that both cholera and the epidemic cerebro-spinal meningitis have attacked many horses. One case is described, but not very fully; the symptoms of the developed malady are said to have been, suppression of the urine, borborygmi, flux, rapid emaciation, extreme tenderness in the region of the lumbar vertebræ, and trembling of the limbs.—(*L'Union Med.* Oct. 27.)

CHOLERA IN THE CHIMPANZEE.

La Presse Médicale (Bruxelles) states, that in August, while the cholera was prevailing at Antwerp, a magnificent Chimpanzee, which is in the Zoological Gardens of that city, was attacked with cholera. It had cramps, vomiting, rice-water stools, general coldness of the body, and an extremely feeble pulse. It was treated with laudanum and sinapisms, and was cured in three days.—(*La Presse Médicale*, Nov. 11.)

SUGAR IN CHOLERA PERSPIRATION.

In four cholera patients the viscous sweat, collected with care from the forehead, the cheeks, arms, and fore-arms, was found by M. Doyère to contain a substance which decomposed the salts of copper in the same way as sugar. M. Doyère hesitates to decide that this substance is sugar, without more certain evidence. The sweat which was not thus thick and viscid, the serum of the blood, the urine, and the stools gave no trace of sugar. The matter vomited by a patient who had taken only Seltzer water gave a considerable precipitate of the red oxide of copper.—(*Archives Générales*, Sept., p. 108.)

THE FRENCH AT ROME.

The *Gazette Médicale* gives an account of the medical state of the French in Rome. Marsh and typhoid fevers (Dothinenterite) are prevailing together with great intensity; and so far from the doctrine of the antagonism of these diseases being true, it seems absolutely overthrown by the manner they are now raging together. Dysentery is uncommon. Phthisis pulmonalis at present seems to be unfrequent, so that the hypothesis of an antagonism between it and marsh fevers has not at present been tested.—*Gazette Medicale*, Oct. 27.) The French surgeons are strongly reminded of the diseases of Algeria.

IMPAIRMENT OF THE SIGHT IN BRIGHT'S DISEASE.

Since the statement of M. Landouzy, that there is impairment of vision, or complete amaurosis in granular disease of the kidneys, M. Levy has minutely investigated three cases. Two of these had no alteration of sight; the third had a slight impairment.—(*Gaz. Med* Oct. 27.)

The following were M. Landouzy's conclusions at the end of his paper read before the Academy:—

1. Dimness of sight is an almost constant symptom of albuminous nephritis.
2. It is an initial symptom preceding all others.
3. It disappears and returns at the same time as the albuminous deposit in the urine.
4. That the ganglionic system of nerves is particularly affected.

M. Forget, of Strasbourg, has published three cases of Albuminuria, in some measure confirmatory of M. Landouzy's observation of the frequent occurrence of amaurosis. In the first case, the anasarca was very considerable; the albumen in the urine in large quantity, the amaurosis nearly complete. The amaurosis had preceded the dropsy, and had been ushered in by obstinate vomiting. In the second case, the feebleness of vision came on gradually in the course of the malady, three months after the dropsy appeared. The urine was very albuminous. In the third case, the patient had suffered from cephalalgia for six years; the amaurosis followed a year after the commencement of the headache. A few months later acute pain in the loins came on, followed by acute superficial pains in the lower extremities. Dropsy and albuminous urine succeeded these symptoms. After death there was considerable hypertrophy of the heart, old pericarditis; the kidneys small, lobulated; the cortical substance deepened, not anæmiated; the pyramids diminished in size, but the kidneys were not, apparently, granular. The head was not examined. The Author thinks that the cephalalgia, the amaurosis, and the darting supeficial pains, probably indicated a cerebro-spinal lesion. In regard of M. Landouzy's conclusions, M. Forget remarks, that where amaurosis exists, it is probably closely allied with the albuminuria, and is not simply a fortuitous and accidental coincident. But he does not admit that it is, as M. Landouzy asserts, almost a constant and an initial symptom. He also doubts whether it disappears and re-appears when the albuminuria temporarily ceases and returns,—for in one of his cases the amaurosis disappeared while the albuminuria continued to advance. He considers M. Landouzy's opinion, that albuminous nephritis results from an alteration of the ganglionic system of nerves, as a mere hypothesis.—*L'Union Méd.*, Nov. 1.

THE TRANSFORMATION OF SUGAR.

M. Bernard seems to have arrived at the conclusion, that cane sugar is transformed into glucose by the action of the gastric juice; but, if it be in too great a quantity to be so transformed, it passes into the vena portæ unchanged, and undergoes its transformation into glucose in the liver. The functions of the liver appear, in part at any rate, to consist of this formation of glucose or assimilable sugar.—*La Presse Médicale*, Oct. 21.

PRODUCTION OF CHOLERA.

M. Pellarin, of Givet, has forwarded to the Académie des Sciences numerous documents on the cholera at Givet, which, he considers, prove that the gases from necessaries and cesspools are the cause of cholera, and that the exhalations of the intestinal discharges are the ordinary agents by which the malady is transmitted.—*L'Union Méd.*, Nov. 1.

REMEDIES AGAINST DRUNKENNESS.

L'Union Médicale states, that the following severe laws against drunkenness have been recently enacted by the Swedish Government with a view of checking the spread of this vice. For the first conviction of drunkenness, a fine of 15 "rix dollars;" for the second, 30 rix dollars; for the third and fourth times, heavier fines, loss of right of voting and of being elected, and, on the following Sunday, public exposure in the pillory; for the fifth conviction, six months' imprisonment and hard labour in the house of correction; for the sixth, imprisonment for a year. A person convicted of making another drunk is fined 15 "rix dollars," or a double sum if the person made drunk be a minor. An ecclesiastic committing a fault of this kind loses his benefice; a layman holding an important post is suspended or dismissed. Drunkenness is never accepted as an excuse for acts committed under the influence of intoxication, and a man who dies drunk is not allowed to be buried in the common cemetery. —*L'Union Med.*, Oct. 30. (The Daily *Times* having copied this from a foreign journal, was informed by a Correspondent that it was incorrect.)

LIGATURE OF THE COMMON CAROTID FOR ERECTILE TUMOUR OF THE FACE OR HEAD

In a discussion in the Academie de Medicine, on this subject, M. Lenoir gave the following summary of the results of the operations which had been performed, viz., out of thirty-one cases in which the common carotid had been tied, there were eighteen cures, eight deaths, and five unsuccessful, but not fatal cases. M. Lenoir remarked on the necessity of making a correct diagnosis between true erectile tumour, and arterio-venous aneurism following injury. In this latter case, the ligature of the common carotid does no good, and the artery involved in the disease must be tied above and below its point of communication with the vein.—*L'Union Médicale*, November 3.

UTERINE DISEASES.

A long discussion has been carried on in the Academie, which presents to us conspicuously the well-known fact, that in the Paris school, where the non-organic diseases of the uterus have received so much attention, very great difference of opinion prevails as to their nature. There are scarcely two academicians who adopt the same view. The principal opinions which have been yet advanced are the following:—

Some Academicians, with M. Gibert, attribute the congestive uterine diseases to a general previous condition of the system, of which these uterine affections are but the expression. A treatment purely general is to be used in all cases. Velpeau and some other Academicians believe, that, putting aside carcinomatous, fungous, and fibrous alterations, the uterus presents few organic pathological alterations. They deny the engorgement of the body of the uterus, since it cannot be observed on *post-mortem* examination. They admit the engorgement of the neck only as an exception; but they say, that, when the neck is affected with vegetations and granulations, —these must be combated by a treatment purely local.

M. Malgaigne, on the contrary, believes engorgement of the neck to be very common.

MM. Roux, Morcau, and Jobert, (de Lamballe,) admit both the congestions of the body and the neck as usual maladies, and praise the application of the actual cautery in some of these cases.

M. Robert admits not only lesions of the uterine tissue, but has described new diseases of the uterine mucous membrane. The most important of the affections of the mucous membrane consists in granulations and little tumours, seated chiefly on the posterior face of the organ, and especially near the Fallopian tubes. These are simple hypertrophied portions of the mucous membrane, or new developments of areolar and fibro-plastic tissue. M. Robert gave no marks by which such a disease could be diagnosed.

The most important speech on the subject was made by M. Huguier, who has treated many uterine cases at the Hospital of Lourcine, and who believes that engorgements of the neck are, with sub-acute and chronic metritis, and uterine folliculitis, the most common diseases of the uterus in our large towns. He appears almost to have established incontestably the fact of the existence of engorgements of the body and neck of the uterus, and has preparations showing its existence after death. Out of 2527 cases, he collected 131 observations of engorgements of some part of the uterus. Of these, 8 were of the body and neck together; 13 of the body alone; 106 of the neck alone; and 4 were undetermined.

M. Huguier admits eight species of engorgements.

The discussion is still going on.—*Gazette Méd. et l'Union Méd.* for Oct. and Nov.; *La Presse Med.*, Oct.

TREATMENT OF CHOLERA.

M Baudrimont (Bordeaux) has recommended, in strong terms, the employment of the bicarbonate of soda in cholera. He explains its utility by presuming that it restores the fluidity of the blood, and acts as a true antidote.—*L'Union Méd.*, Oct. 23.

CHOLERA IN A NEW-BORN CHILD.

M. Homolle has reported an instance in which a woman in labour was attacked with cholera. An infant, apparently asphyxiated, was born, but, after proper remedies, was roused, passed meconium and urine, and appeared to be doing well. Twenty-four hours after its birth, there came on suddenly serous diarrhœa, vomiting, and all the gravest symptoms of cholera, and it died in a few hours. M. Homolle puts the question, whether it was infected with cholera in the womb or after birth. He inclines to the former opinion.—*L'Union Méd.*, Oct. 23.

THE BENEFITS OF CHOLERA.—The dreadful visitation which will soon have swept over the face of all Europe, has brought with it many a lesson, that, it is to be hoped, we shall not forget when the evil has passed away. In England it will accelerate the abolition of that abominable and disgraceful nuisance, interment in towns. On the Continent, it has demonstrated the necessity of instituting parochial medical relief, and measures have been taken already in some of the European states, for the supply of gratuitous advice and medicine to the poor. Thus, in Belgium, for example, the Government proposes to create a class of "district physicians," analogous to our Poor-law medical officers, who are to receive salaries varying from 600 to 1,000 francs, or from 24*l.* to 40*l.* per annum. Even Turkey, as we lately reported, does not remain behind hand. The Ottoman Government has recently published a decree for the appointment of physicians to be paid by the State. They are bound to treat gratuitously all—both rich and poor—who shall demand advice; but, if the medical man show any preference to the rich, he will be punished severely. The State physicians are also bound to send in quarterly Reports of the number of sick treated by them; of the prevalent diseases; of deaths and of the meteorological phenomena observed during the quarter. Finally, the decree contains popular directions relative to the conduct to be pursued during epidemics, and "regulations for the inhumation of all bodies *outside* the towns."

It is said that the celebrated anatomist and physiologist, Tiedmann, of Heidelburg, has retired from public life, from grief caused by the military execution of his son, Commandant of the fortress of Radstadt, in the late revolution.

Complaints having reached us of the irregular delivery of the MEDICAL TIMES *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the MEDICAL TIMES, *147, Strand."*

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, *Strand, or to the News Agents or Booksellers. All Post office Orders should be made payable to the Publishers,* WM. S. ORR AND CO.

THE MEDICAL TIMES.

SATURDAY, NOVEMBER 17, 1849.

DURING the last six months a wide-spread and fatal epidemic has devastated two neighbouring and powerful countries, inhabited by races which, from time immemorial, dispute the palm of civilization. Cholera has counted its victims by hundreds of thousands. They have exceeded, within that brief period, the numbers of slain in the most bloody wars; and as, during homicidal contests, the leaders often suffer most severely, so have the "officers of health" been cut off by their implacable enemy in frightful proportion.

In England, as well as in France, the members of the Medical Profession have nobly performed their duty under the most trying circumstances; they have given proofs of courage, devotion, scientific skill, patient endurance, charity, brotherly love, — in a word, of all those high qualities which most ennoble humanity. Despising danger, they hastened to combat the enemy wherever he appeared. Man after man fell; but the ranks of the survivors "closed up," with undaunted hearts, though diminished numbers. Every thing that science could suggest, experience could promise, or devoted energy supply, was freely offered in the service of suffering humanity. And all this, in a vast majority of cases, with slight prospect of either fee or reward.

The war—to continue our metaphor—is now at an end on both sides the Channel. The battle has been won; or to speak more correctly, the enemy has retired from the field, wearied with carnage. Cholera no longer exists in London or in Paris; and the interests of civilization, to say nothing of justice and gratitude, demand that the survivors of those who conducted themselves so valiantly during the contest, should reap some reward for their labours.

How far public opinion in England may induce our authorities to abandon the barbarous traditions of the Middle Ages, and consider civil services as no less worthy of honour and reward than military achievements, we cannot pretend to say. Such a reform has long been demanded by every enlightened man in the Empire; but custom, routine, and our aristocratic habits oppose it. We shall, therefore, in all probability, continue to walk in this instance in the narrow path that once led to all manner of abuses; but, in the meantime, it is some consolation to know, "that they order these things better in France." There, at least, a popular Government appears to entertain a just sense of the duties which civilisation imposes on it; and there have the members of the Medical Profession already received a small portion of the rewards to which their conduct, during the prevalence of epidemic cholera, so justly entitled them. May the example produce some effect on this side the Channel, if not from a generous motive, through very shame.

The official journal of the French Republic, for Saturday last, contains a long Report from the Minister of Commerce to the President, on the services rendered by the Parisian Practitioners during the cholera epidemic. These services are publicly acknowledged by the Minister in the most handsome terms; and he proposed, by way of recompense, a series of nominations in the Order of the Legion of Honour, which the President immediately countersigned. M. Rostan, the well-known author of a treatise on Clinical Medicine, and M. Merlier, are named officers of the Order. Mr. Stewart Cooper, a laureate of the Faculty, receives the Cross of Knight. In addition to these special appointments, the Cross has been bestowed on one Medical man from each of the twelve arrondissements or parishes of Paris, and on M. Bazet, an apothecary, whose extraordinary exertions have merited this high distinction. And this is not all. A Cholera Medal has been struck for the occasion, and distributed to 600 persons, more or less connected with the Medical Profession. Among those whom the Minister cites *nominatim* in his Report, are Rosalie Render, Sister of Charity at the Hotel Dieu, Madame Mollet and Madame de Vernon; the worthy Curate Hucqueville, and many others. All the Sisters of Charity, in fact, have received the Medal, and all the Students whose particular services entitled them to distinction amongst the crowd of their fellow-labourers.

The Military Surgeons, likewise, obtain their share of reward, but with a more sparing hand, as if this class, in common with our Naval brethren, were always to experience injustice. M. Boudin, of the Military Hospital la Roule, and M. Worms, of Gros Caillon, are appointed Officers of the Legion of Honour; and six Military Surgeons, with two Apothecaries, obtain the Cross of Knights.

Never were honorary distinctions more justly merited. And again we ask, How long shall we have to exclaim, with Sterne, "They order these matters better in France"?

SANITARY CONDITION OF BETHNAL GREEN.

WE have lately read a Work by Dr. Hector Gavin, the title of which we give below;(a) and there are, we believe, few men who could arise from its study with as light a heart as they sat down.

We wish we could say *no man*, but we cannot forget those of the City Council who find invigorating breezes in the tainted air of Smithfield; who, strong in the social feeling, are unwilling, after Atropos has cut the (*to themselves*) precious thread her Sisters spun and wove, that the fragrance of their mortal remains should be wasted on the "desert air;" and therefore desire to rest in "their ward;" to linger, if not visibly, yet still *sensibly* among living men, and to enter literally into their hearts by perfuming the breath of morning, and loading the dews of evening.

Published before the cholera invaded the Metropolis, Dr. Gavin's "Ramblings" is a most interesting and able report on the then sanitary conditions of the parish of Bethnal-green.

It consists of a general sketch of the five districts into which the parish is divided,—a particular description of a great number of streets in each district,—evidently drawn from careful personal observation,—and it concludes with a summary of the preceding sketches and illustrations, embracing a general examination of the structure, size, ventilation, &c., of the dwelling-houses, the supply of water, interments, nuisances, &c.

Plainly does Dr. Gavin depict the necessary physical consequences of the hygienic conditions in which the poor of the parish of Bethnal-green were placed.

The truth of his predictions, unfortunately, the present year has verified. Embued himself with that philanthropy which, we rejoice, is so common in our Profession, Dr. Gavin thought, in the simplicity of his heart, that he had but to lay bare the naked truth; he had but to make the upper and middle classes cognizant of the fact, "that multitudes of their fellow-beings have their health injured, their lives sacrificed, their property squandered, their morals depraved," by causes which it was in the power of those classes to remove, in order that the evils might cease; he believed their apathy arose from ignorance and not from avarice. Dr. Gavin wrote; but, alas! he wrote in vain. Eighteen months elapsed after the publication of his book, and the voice of the advocate of the poor was unheeded.

The Cholera came!

In the middle of August, 1849, Mr. Murray, the Registrar for the Hackney-road district of Bethnal-green, made the following Report to the Registrar-General:—

> "The 12th, 13th, and 14th of August will long be remembered in this neighbourhood;" "the hurried passing and re-passing of messengers, and the wailing of relatives, filled the streets with confusion and woe, and impressed on all a deep sense of an awful calamity." "The deaths chiefly happened in a space of about 400 yards by 150."

This space includes the Nichol-streets, Half, Old, and New, Nichols-row, Turville-street, and the courts, &c., connected with them. With very great interest did we turn to Dr. Gavin's account of particular streets, to see in what sanitary condition these death-struck spots were when he visited them in his "ramblings." The Cholera had not then broken out. His

(a) "Sanitary Ramblings; being Sketches and Illustrations of Bethnal-green. A Type of the Condition of the Metropolis and other large Towns. By Hector Gavin, M.D., F.R.C.S.E. Member of the Health of Towns and of London Association, &c.&c. Churchill. Pp. 118."

mind could have been biassed by no prejudices. The following is the account he gives of Half Nichol-street:—

"On the surface of this street were bountifully strewn all kinds of dust, dirt, refuse, and garbage. It is not cleansed more than once in three weeks or a month; and though cleansed (nominally) only last week, it was as filthy and dirty as if apparently it had not been cleansed for months." "The inhabitants, in order to get rid of their refuse, solid as well as fluid, are compelled to throw it on the streets, there to putrify and be mixed up with the mud. In consequence of the free exposure of the animal and vegetable remains, in a pasty state, to the sun, the muddy compost becomes most offensive to the smell, and a constant cause of disease and death to the inhabitants. *Invariably, wherever such filthy streets are found, so likewise are fever and the other zymotic diseases.* Loud complaints were made to me, that the only way of getting rid of the refuse was to throw it on the streets, as the dustmen would not take it away unless paid for so doing. The inhabitants of this street complained bitterly that "*the people in it never died a natural death, but were murdered by the fever.*" In the back yard of No. 21 in this street, the soakage from the neighbouring privies had permeated through the wall, infiltrated them, and spread itself over the yard, when the offensive soil was covered over, and, as it were, dammed up by collections of dust, cinders, and refuse. The Poor-rate collector complained of this place as a great nuisance."

In Nos. 6, 9, 12, 16, 21, and 22, of this street, eight deaths occurred during the 12th, 13th, and 14th of August. The same street of which the unfortunates who dwelt in it complained in 1848, "that its inhabitants never died a natural death, but were murdered by the fever," was the same street which formed a scene of Mr. Murray's graphic sketch in 1849.

The same house, the walls of the back yard of which Dr. Gavin said in 1848, were infiltrated by night-soil from the neighbouring privies, and the yard itself spread over with the same, only dammed in and covered by cinders and refuse,—this same house, No. 21, was one of the earliest visited by cholera in 1849.

Fever and cholera, cholera and fever, are the alternating visitors of these unhappy abodes.

In Nichol's-row, Dr. Gavin says:—

"A cellar here serves for a dust-bin and a privy."

Of Turville-street:—

"Eight houses are without any supply of water. One privy is common to seven houses. They are *all* nasty, and *horribly offensive.*"

Of Shepherd's-court:—

"Excessively dirty and foul. The privies are confined and dirty. Excrements are scattered abroad."

The other streets above referred to appear to have been in a similar sanitary condition.

Sir John Tyrrell *enjoys the honour* of being the ground landlord of some, at least, of these Fever preserves.

During the progress of the cholera, death, induced by that disease, entered two-thirds of the houses in Half Nichol-street; more than half the houses in Turville-street; nearly half those in New Nichol-street; and more than a third of those in Old Nichol-street.

"The moral bearings of the question are," says Dr Gavin, "too vast to enter on."

Yet with such facts as these before them, men proceed to the temple of an omniscient God, and, on bended knees, supplicate *Him* to remove the pestilence from among them, while *they* leave untouched those second causes, which their own intelligence, His gift, His voice, teaches them must inevitably re-produce the malady. Do they expect a miracle, that the contributions of the wealthy may be spared?

Now, as then, mankind need to apply the fable so admirably told by the enchanting and amiable La Fontaine, which we have ventured to "do" into English:—

AIDE TOI, LE CEIL T'AIDERA.

A wagon, piled high up with hay,
Stuck in a muddy road one day.
The driver raised to Heaven his eyes,
And knowing that his anxious cries
By mortal ears could not be heard,
To Hercules his suit preferred.
"Oh Hercules!"—he trembling said—
"Lend to a wretched man thine aid.
"If it be true that once thy back
"Sustained the world and did not crack,
"Place 'gainst my cart thy little finger,
"And in the mud we shall not linger."
He ceased;—and answering his prayer,
A gentle whisper stirred the air.
"Too soon," a voice spoke in the breeze,
"Thou claim'st the aid of Hercules.
"He wills that man shall do his best,
"And then he comes and does the rest.
"Look well about thee—see the cause
"Which stays thy wagon—Nature's laws
"Are simple in their working—feel
"What mud encumbers every wheel—
"Clear it away—now break that stone—
"Fill up that deepest rut. Hast done?"
"All I have done," the driver said.
"Now," said the voice, "expect my aid.
"Take up the whip." "The whip I've found,
"But, bless me! now the wheels go round.
"Hercules, thanks!" The voice replied—
"Let this truth in thy heart abide:
"*To those who help themselves 'tis given*
"*Alone to hope for help from Heaven.*"

In conclusion, if doubt yet lingers in the mind of any man as to the relation between defective sanitary regulations and the spread of epidemic diseases, we would urge him to make, from the Registrar-General's Weekly Returns, street lists of the mortality from cholera in Bethnal-green, and then to compare those lists with Dr. Gavin's account of the particular streets in the same parish. We will answer from experience, that he must rise from his task, what Dr. Gavin strives to make every man, an ardent Sanitary Reformer, convinced that he has no child's play, but God's work, to perform.

THE REPORT OF THE CITY OFFICER OF HEALTH.

A period of time has now elapsed, which may be fairly designated as the first sanitary year of the City of London. Clumsy as this epithet may seem, frightfully as it may be in appearance contrasted with the ravages of the late pestilence, still it is no less significant than true. A civil government, which has long possessed the power of taking life from the guilty, has at length asserted the right of preserving it to the innocent. At last it has legislated to this purpose; and though partially and imperfectly, and under the disadvantageous circumstances of a vast metropolis and a many-times-delegated authority, yet with sufficient effect to render it both justifiable and necessary to ask, —"What are the results of these recent enactments, and what must be the aims of the future?"

When the present Ministry first showed symptoms of yielding to pressure from without, and condescended to listen to sanitary necessities, the Medical Profession fully expected that their services would be essentially requisite to the settlement of the question. Nor was the anticipation altogether unnatural. They had shown their skill by the detection of these evils, their zeal and philanthropy by the exertions which they had made to suppress them. Their disinterestedness had merged in the claims of a common humanity that obvious relation borne by disease to the Medical Practitioner as a means of subsistence. For the Palace Courts of sickness they neither expected nor claimed compensation; nor did any vested interests induce them to abet cruelty and injustice, or harass the defenceless poor. But, being specially educated to comprehend the laws of organized nature, and to treat their deviations, they had a right to presume, that a subject which was altogether included within the range of their thoughts and lives, and excluded from the understandings of others, would be specially entrusted to them.

We need not remind our readers how these expectations have been, in a great measure, disappointed. We need not point to the astounding organization of a non-medical Board of Health,—a body which cannot possibly know what health is, even if an unwonted share of self-knowledge should give it a few stray heads of information as to the composition of a board. Nor do we care to recal the equally wonderful details of its career: it may suffice to say, that it was not merely useless, but hurtful; and that, had its zeal only equalled its ignorance, or had its official advice been as widely followed as diffused, it might have constituted a powerful auxiliary to the very disease against which it was nominally organized. As it was, the wholesale poisonings which were attempted, both in diet and medicine, rendered it necessary for the first Medical Body in the Kingdom to interfere. So exposed and frustrated, the Board of Health may be best dismissed with quiet contempt. Its ludicrous quackery deserves no severer punishment, than that it should be stamped—either with incapacity or thirteen-pence-halfpenny, — we hardly know or care which were best.

Our present object, however, leads us to far other and more agreeable duties than that of dispensing the justice of the Press to this useful and scientific Commission. Some members of our Profession have been appointed agents of Sanitary Reform; and one of those, the Officer of Health to the City of London, pre-eminent both in himself and in the magnitude and importance of his duties, has just laid before the Court of Sewers his Annual Report; while, through the daily papers, this Report has reached the public, backed by the useful help of able leading articles. By this time, we doubt not that many thousands have read it with an interest commensurate to the importance of its contents,—contents which, while they accurately record the fatal events of the past year, also bid fair to render it a recognised manual of sanitary science.

At present we shall neither enter into the details of this Report, nor attempt to abbreviate its brevity in the Procrustean bed of an ordinary newspaper analysis; the less so that we trust there are few of our readers who have not studied it with care. Nor do we intend to load it with its well-earned tribute of critical praise. That it is clear and lucid in arrangement, full

but condensed in its matter, cautious and truthful in its statements, and, in fine, admirably written, is what we can rarely say of the writings that come before us; but is, in this instance, no exaggeration. Still all this might have been expected beforehand. Although the Officer of Health to the City is a man who, perhaps unfortunately for himself, will not speak unless he has something to say; yet, even with this unusual limitation, he is well known by his published writings as one of the first English physiologists and pathologists of the present day, and as one whom the Common Council ought to be glad to secure as their officer, and ashamed so meagrely and inadequately to reward.

It would seem impossible but that our Profession, as a body, must ultimately take a very great share in the execution of sanitary duties; and, in consequence, it becomes very important to notice in what manner a prominent member of our body takes the initiative in these new functions, and how he fulfils them. Regarding the Officer of Health under this view, there is much in his conduct rendering it worthy of remark and of imitation. He appears to have secured the cordial co-operation and respect of that very able and deserving body, the Union Medical Officers; while another very serious difficulty, the adjustment of his new sanitary duties with the forms of a previously existing municipal organization, has been surmounted in an equally honourable, if not an equally satisfactory manner. While we cannot but concede great allowances for the disturbed prejudices of a Corporate body, chosen from among classes necessarily uninformed upon these subjects, still we feel glad to observe that no risk of displeasure or expulsion from office has deterred the author of this report from performing the whole of his duty. We have been informed that, amongst the Corporation of London, there are many who consider that their Officer has far exceeded the bounds of his duty; and that his suggestions are not only reprehensible on this ground, but are also impracticable or ruinously expensive. Indeed, it has been surmised that a sum approaching two hundred millions would be required to carry out all the propositions alluded to in the Report. But the document itself fully exculpates the Officer of Health from all charge of overstepping his legitimate functions, since it shows, that with the question of practicability he is but indirectly concerned; and that, whatever becomes of his suggestions, the setting them forth is expressly stipulated for in the Act of Parliament which defines the duties of his office. And we would add, that the impracticability most to be dreaded is, not what the City cannot, but what it will not do. Even assuming the sum estimated to be correct, there is no necessity for its immediate expenditure, far less for its immediate payment. But when we recall the expensive though ludicrous spectacle of the ninth of November, so lately past, and recollect the sums annually wasted on similar absurdities, or spent in the merest edacity, it is impossible to avoid coming to the conclusion that the City has funds at its disposal beyond the necessary municipal expenditure,—funds which constitute a talent for which its rulers are collectively responsible to God and man. Let a sufficient portion of its vast Corporate income (to be increased, if need be, by increased rates) be annually devoted towards sanitary reform, and neither public opinion, nor the press which represents it, will have the wish, or the power, to complain. While, on any other terms, not even the armoury of their worshipped turtle can preserve the Corporation of London from attacks as continual and lasting as the necessity which gives rise to them.

Finally, it is our agreeable duty to state, that the judicious boldness and independence displayed by Mr. Simon in the present Report, are more calculated to advance the real dignity of the Profession than many speeches and letters on Medical Reform. And contrasting his almost solitary and ill-paid services, with the plural constitution of the Board of Health, and the Government machinery at its disposal, we may fairly deduce that, setting aside all other claims, not only are members of the Medical Profession best fitted by education and habits for such offices, but that they actually are, in practice, the most talented, honest, and, in one word, serviceable, agents of Sanitary Reform.

TYPHUS FEVER, TYPHOID FEVER, RELAPSING FEVER, AND FEBRICULA,

THE DISEASES COMMONLY CONFOUNDED UNDER THE TERM CONTINUED FEVER.

ILLUSTRATED BY CASES COLLECTED AT THE BED-SIDE.

By W. JENNER, M.D. Lond., Professor of Pathological Anatomy, University College; Assistant Physician to University College Hospital, &c.

Some years since I was, in conjunction with one of the most able physicians of the day, a man of great experience, in attendance on a young lady supposed to be labouring under acute idiopathic peritonitis. Death ensued. Fortunately permission was obtained to examine the body. We discovered tolerably extensive ulceration of Peyer's patches, and enlargement of the mesenteric glands; in fact, the anatomical characters of typhoid fever. It was evident that an error in diagnosis had been made. The question then arose, which under such circumstances the practitioner always ought to ask, was the art of medicine defective in not affording means for the diagnosis, or were we behind the age in the information we possessed? (a) I was so struck with the importance of the question, that I determined to investigate the subject of fever on a large scale, if ever opportunity served. Through the kindness of the medical officers of the London Fever Hospital, I have during the last four years been enabled to undertake such researches in an extensive field, and with the greatest facilities for prosecuting the inquiry.

The object of these papers is to illustrate what appears to me to be the state of our knowledge at the present moment on the subject of the diseases commonly called continued fever. I lay little claim to originality. I had no theory to substantiate when I undertook the investigation; I have now no theory to propound. I lost a case which had baffled my knowledge in discovering its nature, and I was only anxious that I might never again commit the same mistake. If, during these researches, I have been led to adopt views not generally acknowledged as correct in this country, it is only because I am unable to withstand the evidence which nature offers of the truth of those views, *where alone* the truth can be elicited, at the bed-side and in the dead-house.

There are two opinions entertained on the subject of continued fever. The first, which is that generally held in this country, may be stated thus—continued fever is one disease, capable of assuming different forms or types, as inflammatory, ataxic, &c.; the stress of the fever may fall on any one organ, and so give rise to the varieties termed bilious fever, brain fever, &c.; the symptoms of this disease vary infinitely according to atmospheric, individual, and hygienic peculiarities; consequently there can be no definition of fever applicable to more than the epidemic prevailing at the time the definition is given; by these atmospheric and hygienic peculiarities are to be explained, the differences in the disease, as observed in Paris and Edinburgh, and its variations at different times in the latter city. Some even go so far as to maintain, that hygienic conditions may develope the poison of plague out of that emanating from a person labouring under typhus fever.

The second and much less commonly received opinion, I say less commonly, but in reality it is not taught in a single systematic work on fever in this country, may be thus stated:

Under the term continued fever are confounded three, if not four fevers, each having its origin in a specific cause; and granting all to be contagious, the poison of one fever is altogether incapable, whatever may be the individual or hygienic conditions existing, of exciting the other. Each is a general disease, capable of being complicated with local lesions; one of the four, however, is constantly attended by a lesion peculiar to it. This morbid structural change so invariably accompanies the general symptoms of that particular fever, that even if the local symptoms which ordinarily indicate the existence of that change be absent, yet, if the *general* symptoms of that fever are present, we may predicate, with absolute certainty, that the lesion alluded to is present also; (the bearing of this fact on prognosis is of incalculable importance.) Perhaps the truth is, however, scarcely expressed by the assertion, that the general state is attended by the local lesion; for the latter is as much a part of the disease, as sore throat is a part of scarlet fever; nay, even more so, for angina is not so constant a concomitant of scarlet fever, as lesion of Peyer's patches is of typhoid fever.

The two opinions, which I have above endeavoured briefly to state, may be illustrated thus,—Suppose a common lodging house, each room of which is in a different hygienic condition, if a person labouring under any form of continued fever,—say those who maintain the identity of the fevers I believe to be different—be admitted into room No. 1, he may produce or excite in the inhabitants of that room typhus fever, with the mulberry or measly rash, or spotted typhus, as it is sometimes called; if he then be removed into No. 2 in the same house, the occupier of that room, inhaling the same poison as did the inhabitant of No. 1, may have short or relapsing fever; the dweller in No. 3, febricula; while the resident in No. 4 may catch from the same person continued fever, complicated with ulceration of Peyer's patches and enlargement of the mesenteric glands; and if—some go so far as to maintain—highly unfavourable hygienic conditions exist in another room in the same house, then may the unfortunate who inhabits it have true oriental plague, as a consequence of inhaling the breath of the man labouring under typhus fever. They further maintain that an eruption on the skin may be present or absent in either, in all, or in none, of these cases; that if present, it may consist of a few rose spots, an abundant exanthematous or mulberry rash, petechiæ or true plague buboes; and that it would be impossible, judging *from the eruption alone*, to predicate the presence or absence of lesion of Peyer's patches and enlargement of the mesenteric glands.

Those who maintain the non-identity of certain continued fevers, say, on the contrary, if a man labouring under typhus fever, *i. e.*, a continued fever, having a determinate duration, and attended

---

(a) In justice to the accomplished physician referred to, as well as to myself, I ought here to anticipate, and state that this case presented peculiarities which defied diagnosis so long as the idea of continued fever, severe enough to prove fatal, was confined to cases presenting a brown tongue, delirium, and extreme prostration.

by a peculiar rash, but unaccompanied by lesion of Peyer's patches, be admitted into room No. 1 of a common lodging-house, he can excite in the inhabitant of that room no other disease than typhus fever; that this disease, like all others, may vary in severity; that the dweller in the infected atmosphere may, according to various external, and also individual peculiarities, have a mild or a severe attack, but that the disease will present the symptoms—however different they may be in degree or in number—and, if it prove fatal, the pathological appearances observed in typhus fever, and that the disease will preserve its characters, varying only in severity and number, whether it be communicated to the dwellers in one or all of the rooms of the house; that if a person labouring under what they term another disease, viz., typhoid fever,—*i. e.*, a fever having a determinate duration, accompanied during life by a peculiar eruption, and presenting after death lesion of Peyer's patches and enlargement of the mesenteric glands,—be admitted into the house, he, too, may communicate fever, (a) but then it will be typhoid fever, that as in the first case rose spots and lesion of Peyer's patches were present, so the same eruption, if any and the same lesion will occur in all the cases which have fever from contact with, or proximity to the first case, and this whatever be the individual peculiarities, or external hygienic conditions in which they are placed; exactly as a person labouring under scarlet fever, if admitted into the different rooms of a lodging-house, would excite in the inhabitant of those rooms, scarlet fever, and that disease only, however much the hygienic conditions of its rooms might vary, and however different the individual peculiarities of their inhabitants. Individual and hygienic peculiarities might modify the severity of the disease; but, *if any* eruption occurred, it would be that characteristic of scarlet fever; if any serious lesion, it would be sore throat. The duration of the scarlet fever thus produced would be the same in a large proportion of the cases, though some might have their illness prolonged by local complications, and others might have the disease in so mild a form that they might consider themselves well ere the symptoms characteristic of the diseases, to the eye of the experienced physician, had entirely disappeared. But, however much the hygienic conditions of the rooms might vary, no modification in the poison exhaled could be produced by which it could be converted into a different poison capable of exciting another contagious disease, *i. e.*, one able, like the first, to reproduce itself. Thus a person suffering from scarlet fever cannot produce a poison capable of exciting small-pox, nor *vice versâ*.

The question is not one barren of practical results, as they are termed, (as if *all truths* were not practical,) for, of what avail can be any observations respecting treatment, general or particular, so long as two, three, or four diseases are called by one name. Let me, in illustration, refer to the fact, that measles and scarlet fever were long confounded under the same name. What value could be attached to any observations respecting the efficacy of the treatment of a class of cases in which were confounded two diseases so different in their essential nature as scarlet fever and measles?—diseases, of which not only does the medicinal treatment differ, but the hygienic conditions suited for the one are diametrically opposed to those fitted for the other. For one moment suppose the two, as not many years since they were, thus confounded; a Medical man treats a hundred cases, of which ninety are examples of scarlet fever, ten of measles; he will arrive at the conclusion, that cold sponging is highly beneficial in the treatment of the disease, and he adduces his experience in confirmation of the statement. Now, let us reverse the case, and suppose that another practitioner has one hundred cases of these two diseases, confounded under one name, to treat, and that, of these one hundred cases, ninety are examples of measles, ten of scarlet fever. He uses cold sponging, opens the windows, allows his patient to lie exposed while the eruption is out, &c. He looses a large proportion of his one hundred cases, and finds, on examination after death, pneumonia in every case. He instantly avers, that the treatment declared by the first to be so advantageous, is most deadly, and forthwith advocates a line of treatment diametrically opposed to that which had proved so efficacious in the first practitioner's hands. The same holds true with respect to continued fever: if three or four diseases are united by one name, and then a line of treatment is stated to be successful in continued fever, with what confidence can we receive the statement?

In the epidemic which visited Edinburgh in 1817-20, bloodletting was practised in every case, and was supposed to cut short the fever because, soon after the bleeding, the symptoms disappeared; now observation has proved that a disease, presenting all the symptoms noted in that epidemic, will get well in a short time if left to the unaided effort of nature, and that the inference drawn, that it was possible to cut short true typhus fever by bloodletting, was most erroneous, the disease which was then treated by bloodletting being a totally distinct disease from typhus, but confounded with it. One consequence of the supposed success obtained in bloodletting in that epidemic, was the extensive employment of the same remedy in the true typhus, and incalculable loss of life as a result. Bloodletting is practised with advantage in the common continued fever of Paris; in Scotland wine is the mainstay, and bleeding is stated to be most injurious. Mere difference in epidemic constitution, say the advocates of the identity of the disease in those cities. Two distinct diseases, requiring different modes of treatment, say those who regard them in the light in which I am in these papers about to describe them. There cannot remain a doubt on the minds of those who have treated both diseases on a large scale, during the *same epidemic constitution* and under the *same hygienic peculiarities*, that typhus fever, *i. e.*, the ordinary fever of Edinburgh, requires wine to be administered, and often largely; while typhoid fever, *i. e.*, the continued fever of Paris, and a very common disease in London, demands wine much less frequently, and bears depletion much more easily, nay, often derives marked benefit from it.

Having attempted thus briefly to show that it is of no trifling importance to distinguish two or more diseases confounded under one name, before anything like practical directions for treatment can be offered, I may state, that my intention is merely to give such descriptions and illustrations of the diseases commonly termed continued fever, as shall enable the practitioner to discriminate them from each other with facility. In proof of the ease with which the diagnosis between the two most important,—viz., typhus and typhoid fevers,—can be made, I may state, that the nurses of the London Fever Hospital rarely fail to distinguish between the two; and I am constantly answered, when asking them if any new cases have been admitted, by "Yes, Sir, a case of typhoid or a case of typhus fever," as it may happen, and it is not common for me to have to correct their diagnosis.

I have no intention of attempting to *prove* in *these* papers what *I affirm*,—viz., that each of the diseases here described are really distinct from each other, in the same sense as are scarlet fever and small-pox. That I have already done elsewhere, so far as concerns the symptoms and lesions of typhoid and typhus fevers (a); and I have now in my possession the materials for giving the final proof of their non-identity, by showing that their exciting cause is different. These materials consist of an analytical examination of all the cases in which more than one patient has been admitted from the same house into the London Fever Hospital during the last three years.

The plan I propose to adopt in these papers, is, in the first place, to detail a few cases illustrating the ordinary uncomplicate form of each disease; then to sketch briefly the principal features of that disease in a severe form, with the pathological appearances usually observed in the uncomplicated disease; and, finally, to illustrate the various anomalies and complications of that disease, incidentally referring to the treatment.

For the accuracy of the facts and observations, and for the soundness of the opinions expressed, I am alone responsible. The treatment of the cases has been conducted by the Physicians of the Hospital, Dr. A. Tweedie and Dr. Southwood Smith.

Case 1.—Shortly after exposure to the contagion of fever, accompanied with mulberry rash, and without lesion of Peyer's patches, as proved by examination after death:

Ensued, Sudden debility—Headache—Rigors—Constipated bowels—Mulberry rash—Mental confusion—Delirium—Dry, brown tongue—Extreme prostration—Rapid pulse—Death on the thirteenth day.

Thirty-six hours after death.—Persistence of spots noted during life—Partial loss of cadaveric rigidity—Congestion of the brain and pia mater—Blood beneath the lining membrane of pharynx—Intestinal mucous membrane normal—Mesenteric glands healthy—Liver flabby—Spleen softened—Lungs intensely congested posteriorly—Heart flabby.

J. M., a locksmith, aged from 65 to 70, was admitted into the London Fever Hospital, February 1, 1849, under the care of Dr. Tweedie, an aged-looking, thin man, with grey hair. His residence was an empty house, of which he had charge, 14, London-street, Islington. He had been in the habit of visiting a family named Penny, who lived about one mile from his home. Two of these people were admitted into this hospital a little while since, with well-marked symptoms of typhus fever. The father, aged 46, died, and Peyer's patches and the mesenteric glands were healthy. The son, aged 15, is still in this hospital; he, too, had well-marked mulberry rash. This man, J. M., cleaned out the house of the Pennys, which was in a most filthy state, the week before his present illness commenced. He is of sober habits, but has lately suffered from great want.

January 25th, 1849, he was suddenly seized, about three p.m., with a sense of weariness, pain in his limbs, headache, rigors, and chilliness. His bowels were confined, so that he took two doses of calomel, 5 grains each, an aperient draught, and some jalap. He took to his bed on the first day of his illness and has not left it since. His wife, from whom this history was obtained, noticed his mind to wander three days before his admission. He had had no epistaxis. The following was his state when the first notes of his case were made, on the 11th day of disease:—

He had passed a very restless night, and had but little sleep. He was dozing at the time of the visit, talking in his sleep. There was twitching during sleep of the muscles of the face, arms, and neck. His mind, when he awoke, was found to be very confused. He had no idea where he was, nor how long he had been in the hospital; but he knew those around him. His complexion was particularly muddy. His face was pale; there was no increased vascularity of the conjunctivæ, and the pupils were natural. He was quite unable to leave his bed unassisted, and even turned with some difficulty. His lips were dry; the tongue dry and covered with dark brown rough fur. His bowels confined for the two days preceding his admission, had acted twice since from castor oil; there was no appetite, some thirst, no fulness, resonance, tenderness, nor gurgling of the abdomen. The pulse was 120; very weak. There was much cough;

(a) I assume here, for the sake of elucidating my position, that typhoid fever is contagious. I am, of course, aware, that the contagious nature of typhoid fever, unlike that of typhus, admits of reasonable doubt.

(a) See a series of papers by the author in the *Monthly Journal of Medicine*, for April, June, and subsequent months of the present year, "On the Identity of Typhoid and Typhus Fevers," &c. I may add, that during more than three years' almost daily attendance at the London Fever Hospital, I have not seen nor heard of one exception having occurred among fatal cases to the rule, that fever, accompanied by the rose spots, is also attended by disease of Peyer's patches and the mesenteric glands, and that fever, with mulberry rash, offers, after death, no lesion of the same organs.

the respiration was 30, and quiet. He expectorated a little frothy, tenacious mucous.

Physical chest signs.—Some slight want of resonance posteriorly over the most depending part of lungs. At the same place was heard unequal, coarse, sub-mucous râle, and breath sound appeared as if muffled.

The skin was warm, dry, and spotted.

The spots were very numerous, and there was an abundant subcuticular rash; some of the spots faded on pressure, others were unaffected, none disappeared, none were elevated. They were darker in hue on the back than elsewhere. The dorsum generally was much congested; there were no miliary vesicles.

Gin, 4oz. mist. am. carb. 4tis horis; jus bovs. On the 12th day the pulse had risen to 160, and was very weak, the respiration was 36. He had passed a very restless night; lay night and day with his eyes open muttering unintelligibly. The expression of prostration was much more marked, and he turned in bed with great difficulty. He opened his mouth when told to show his tongue, but made no effort to protrude it. The twitching of the muscles continued,—the conjunctivæ were considerable more injected than natural.

The gin was increased to 6oz. He died at 3 a.m., on the 4th of February, *i.e.*, the 13th day of disease.

The body was examined 36 hours after death, and the following appearances noted:—

Cadaveric rigidity disappearing from upper extremities still tolerably marked in the knees and toes. Abdomen concave. Some greenish discolouration of the flanks and abdominal parietes. Scattered over the whole surface of the trunk and extremities were numerous purplish spots, (*i.e.*, those noted during life). The posterior surface of the body was much discoloured. The spots above referred to were on the discoloured parts darker than elsewhere.

Head.—There was considerable subarachnoid effusion. Opacity and thickening of the arachnoid, especially over the anterior lobe. The pia mater was congested. The arachnoid and pia mater separated in one mass from the convolution, and without removing any of the grey matter. There was a little serosity in the lateral ventricles, and about 1 ounce at the base of the brain. The red points throughout the grey and white matter were more numerous than usual. The substance of the brain, including the central parts, was firm.

The *tongue* was covered with dry brown mucous. The *pharynx* was pale, and there was a little effused blood beneath the mucous membrane of the uvula. The *œsophagus* was dusky purple. The cartilages of the *larynx* were ossified; its lining membrane was pale. The mucous membrane of the trachea was pale and healthy.

There was no fluid in either pleura.

The *left lung* was bound by old adhesions at the apex to the costal pleura; it contained several cretaceous masses. The posterior part of theinferior lobe contained *much* frothy, dirty, reddish serosity; most abundant in the *most depending part*. The texture of this part was softened, its colour *dark* brownish red.

The *right lung* was united to the costal pleura by universal old adhesions; it generally resembled the left.

The bronchial tubes contained much frothy mucus; their mucous membrane was dusky red; its thickness and consistence appeared natural.

The *pericardium* contained about 1 drachm of transparent yellow serosity. The heart was slightly enlarged; its lining membrane was stained on the right side. The valves were healthy, the substance flabby.

Much dark fluid blood, and some loose black coagula escaped from the venæ cavæ and pulmonary veins. The right auricle and ventricle, and the left auricle, were distended with black lobuly coagulated blood; the left ventricle contained a little fluid blood.

In the pulmonary artery and aorta respectively was a smooth clot moulded to the sigmoid valves.

The pyloric half of the lining membrane of the *stomach* was covered with thick mucus. There was no mammillation of that membrane; the consistence and thickness of which was natural. Its colour was *pale* dusky red. The colour, consistence, and thickness of the mucous membrane of the *small and large* intestines was natural throughout. Peyer's patches were very indistinct. There was no enlargement of the mesenteric glands.

The *liver* was flabby, otherwise normal. The *gall bladder* was distended with thick dark greenish bile; its lining membrane appeared healthy.

The *pancreas* was pale and healthy.

The *spleen* weighed 8 oz., and was very much softened; rapidly becoming pulpy on exposure.

The kidneys were healthy in appearance.

The urinary bladder was not examined.

Case 2.—After exposure to the contagion of fever, accompanied with mulberry-rash, and without lesion of Peyer's patches, as proved by examination after death:

Ensued, Sudden frontal headache—Loss of appetite—Extreme chilliness—Bowels regular—Very scanty epistaxis—Mulberry rash—Little loss of strength till ninth day, then sudden and extreme prostration—Mental confusion—Somnolence—Delirium—Dry brown tongue—Absence of abdominal symptoms—Quick pulse—Profuse sweats—Death on the fourteenth day.

Twenty-nine hours after death: Persistence of spots noted during life—Marked cadaveric rigidity—Clots in the cavity of the arachnoid—Congestion of the pia mater and cerebral substance—Intense congestion of the most depending part of the lungs—Heart flabby—Absence of intestinal and mesenteric lesion—Liver flabby—Spleen softened—Separation from basement membrane of the epithelium of œsophagus, kidneys and bladder.

George W., aged 49, a native of London, a labourer in the docks, was admitted into the London Fever Hospital, August 15th, 1849, under the care of Dr. Tweedie. A thin man, with light hair and eyes, and fair skin. His wife was received into the hospital at the same time with himself. (a) He stated that his previous health had been very good, that he had never been confined to his bed before. He affirmed that he was of temperate habits, but this was doubtful.

Present Illness.—About three p.m., on Friday, August 10th, 1849, he was seized with frontal headache. On the following day his appetite failed him, and the pain in the head increased in severity. On the third day he complained of chilliness, and felt so cold that he "could have crept into the fire." He lost a few drops of blood from the nose as he came to the hospital on the 15th. His bowels were regular from the outset, and there had been no vomiting.

Present Symptoms.—August 16th, seventh day of disease.—He slept well last night (*i. e.*, first night in the hospital). His mental powers appear unaffected. The expression of his countenance is nearly natural. He complains of much frontal headache; there is a little vertigo. His special senses are unaffected. The conjunctivæ are somewhat more injected than natural; the pupils are normal.

He walked up stairs on admission last evening unassisted, and now leaves his bed with facility. His position in bed is unconstrained.

His tongue is white, and rather dry in the centre. He has passed, since his admission, four formed stools. He has trifling pain about the umbilicus. There is no fulness, resonance, tenderness, nor gurgling of abdomen.

The pulse 96, is full and soft. There is no cough. The physical chest signs are normal.

The skin is warm, dry, and spotted. The spots are not very numerous on the trunk, but are found in greater number on the extremities. They are not elevated; some disappear; some *fade only* on pressure. Those on the fore-arm and backs of the hands are larger and of a brighter hue than elsewhere; the large majority of these disappear on pressure.

Mist. am. acet.; jus bovs.

On the eighth day somnolence commenced; at the same time his mind became dull and his memory defective. Time being prolonged. The somnolence and mental confusion increased. On the tenth day he complained that he felt his mind was wandering, that he had "*appeared* to travel hundreds of thousands of miles during the night." There was no actual delirium at this time. He knew the name of the day on which he entered the hospital, but thought he had been in eight instead of five days. The conjunctivæ were at this time considerably injected, and the somnolence was almost constant. On the eleventh day he was delirious night and day when aroused from somnolence; the stools and urine were passed into bed.

The somnolence was less constant on the 12th day. The pulse, 96 on the 8th day, was 108 on the 9th, and 120 on the 10th day, which rate of frequency it maintained till the last note was taken on the 13th day.

His tongue on the 9th day was dry brown, and continued unchanged in appearance till his death. He left his bed with difficulty unassisted, on the 9th day, but on the 11th day he could scarcely turn without aid. On the 12th day, he appeared somewhat improved, less somnolent, and more sensible, for he asked to be assisted on to the close pan. He turned in bed also, unassisted, at will. His bowels continued regular, acting twice daily. The stools were solid. The following notes were made on the afternoon of 13th day of disease, *i.e*, that preceding his death:—

"Pulse 120, extremely weak. He is sweating profusely. The nurse states, that he has perspired so much, that his clothes have been soaked through. The skin is cool; the spots are well out, and little affected by pressure on the back. The backs of the hands have a somewhat livid hue. He slept little during the night, but has dozed the greater part of to-day. He is delirious when awake. The conjunctivæ are injected, the left very much less so than the right. He opens his mouth, when told to show his tongue, but makes no effort to protrude it. He is unable to move unassisted in bed. There is some catching of the hands, and *subsultus tendinum.*"

He has passed two watery stools into bed.

The treatment adopted was stimulant. On the 8th day of disease 8 oz. of porter were administered; on the 9th it was increased to a pint. 4 oz. of gin were added on the 10th day, and carbonate of ammonia, in doses of 5 gr., was administered every four hours, in addition to the other stimulants on the 11th day.

He sank gradually, and died at 10 a.m., on the the 23rd August, *i. e.*, the 14th day of disease.

The body of George Warren was examined at 3 p.m., August 24, *i. e.*, twenty-nine hours after death.

Height, 5 ft. 5 in.; length of trunk, 21½ in.; breadth of shoulders, 15 in.

The cadaveric rigidity was well-marked. Numerous purplish spots, the remains of those observed during life were visible on the anterior surface. The posterior surface of the trunk and extremities were of a port-wine hue, dotted over with spots of a much deeper colour, the latter the remains of spots seen before death. The discolouration gradually faded as it approached the anterior surface. The parietes of the iliac fossæ were of a very pale greenish hue; the abdomen concave. The muscles were dark; there was about half an inch of fat on the walls of the abdomen.

Head.—The dura mater appeared normal. On the convex surface of the right hemisphere of the brain, within the cavity of the arachnoid, near the junction of the anterior and middle lobes, and about 1½ inch from the longitudinal fissure, was a crimson and black clot, (*i. e.*, its colour varied with its thickness,) thin, flat, about an inch in diameter. A similar clot was found between the anterior lobe and the *falx cerebri*. Over the convex surface of the left hemisphere, also within the cavity of the arachnoid, were scattered six clots, each about the size of split

(a) This woman's case will be detailed in a subsequent paper. She laboured under well-marked typhus fever, and died on about the twenty-eighth day from the outset of her illness.

pess. A little bloody serosity escaped on dividing the dura mater. The arachnoid covering the convex surface, especially of the middle lobes of the brain, was considerably thickened, and had a milky, semi-opaque appearance. There was a little colourless serosity beneath the arachnoid, slightly elevating that membrane at places, and also infiltrating the pia mater. There was considerable injection of that membrane between the cerebral convolutions. The arachnoid and pia mater separated from the cerebral surface *in one mass*: no portion of the grey matter, however, came away with them. The grey matter of the convolution had a pinkish hue, more marked next the white substance than on the free surface. The red points in the white substance were rather more numerous than is normal. The lateral ventricles contained about one drachm of transparent, colourless, serosity. The vessels of the plexus choroides and the venæ corp. striat. were distended with blood. The cerebral substance, including the commissura mollis, (a) and other central parts, was of good consistence. About half an ounce of serosity was found at the base of the skull, but no clots.

The *tongue* was pale brown, and covered, as was the *velum pend. palat.*, with thick mucus.

The *pharynx*, *œsophagus*, *larynx*, and *trachea*, were healthy in appearance, but there was no trace of epithelium on the œsophagus, and the larynx contained some thick mucus.

There was no fluid in either *pleura*.

The apex of the left lung was firmly adherent to the costal pleura, and in the substance of the apex were several collections of mortar-like matter.

The posterior portion of the inferior lobe was of a deep, brownish-purple colour, and gave exit, on section, to a considerable quantity of red, slightly aerated serosity; on pressure this fluid gushed out. The pulmonary tissue was, however, crepitant, and floated in water. The most depending parts were the deepest in hue and contained the least air. The anterior portion of the lung was pale and somewhat emphysematous.

The right lung resembled the left in all particulars, except that the congestion of the posterior part of the inferior lobe was more marked; and here and there, from its most depending part, very small pieces could be cut which sank in water; there was no line of demarcation between the consolidated and non-consolidated tissue; the latter sank in water when slightly pressed before immersion.

The bronchial tubes contained very little mucus; their lining membrane was of a dull red colour.

There was no enlargement of the bronchial glands.

The pericardium appeared healthy; it contained about three drachms of transparent yellow serosity.

The *heart* slightly enlarged; was very flabby, both sides being equally affected. The endocardium was stained of a dull reddish colour. The right auricle and ventricle contained a moderate-sized, black, and soft fibrinous clot. The left side of the heart was empty. The valves were healthy. Some fluid dark blood, and two or three very small loose black clots escaped from the venæ cavæ and pulmonary veins when the heart was removed.

The mucous membrane of the *stomach* was mammillated throughout, from cardiac orifice to pylorus, excepting only a narrow band along the smaller curvature. There were numerous rugæ along the greater curvature. The consistence of the mucous membrane was firm; its thickness somewhat increased. Strips of half an inch were readily obtained from the anterior surface of the stomach, and seven-eighths from the great cul de sac. Its colour throughout was a delicate, pale, yellowish red grey.

The *small* and *large intestines* were pale and healthy in consistence. Strips of mucous membrane, of ordinary length, were readily obtained.

Peyer's patches were normal in appearance. The mucous membrane covering them was of good consistence. The mesenteric glands were scarcely visible.

(a) When examining the brain, I have alway noted the consistence of the commissura mollis, be cause that is one of the first parts of the organ to suffer from cadaveric softening.

The *liver* was very flabby, and tore with facility. It was of a pale yellowish liver colour.

The gall bladder contained about half an ounce of exceedingly thick bile, green in mass. Its lining membrane appeared normal.

The *spleen* weighed seven and a half ounces. It was decidedly softened.

The *pancreas* was pale and healthy.

The *kidneys* were healthy. A milky fluid was expressed from the mammillæ. The mucous membrane of the urinary bladder was somewhat congested posteriorly. It contained about half an ounce of milky fluid.

The turbidity of the fluid expressed from the kidneys, and of that contained in the bladder, was due to the large number of epithelium scales they contained. Those in the fluid from the bladder were evidently detached from the lining membrane of that organ.

Case 3.—After exposure to the contagion of fever, accompanied by mulberry rash:

Ensued, Sudden attack of pain in limbs—Severe rigors—Heat of Skin—Slight headache—Some loss of mental power—Sudden debility—Bowels regular—Frequent vomiting—Muddy hue of face—Mulberry rash—Tongue somewhat dry and brown—Pulse quick—Absence of abdominal signs—Deafness, 12th day—Marked improvement on 13th day—Recovery—Death on about 40th day from small pox.

J. H, aged 26, an agricultural labourer, not in want of food, but residing in a crowded small room, at Islington, was admitted into the London Fever Hospital, November 3rd, 1848, under the care of Dr. Tweedie. His brother was received into the hospital at the same time, labouring under typhus fever, and covered with well marked mulberry rash. He was a strong made, moderately stout, dark man, who had never suffered a day's illness till the present attack.

On Saturday, October the 28th, 1848, he was seized with pains in the limbs, severe rigors, several times repeated, and each time followed by heat of skin, but there was no sweating; there was, at the same time, slight frontal headache. He vomited several times before his admission. His bowels were regular from the outset. He took to his bed on the Sunday morning, because he "felt too ill and weak to keep about."

The following note was made on the 8th day of disease:—"He slept well last night. The mind is dull, the expression heavy; the face is dusky red, and has a somewhat muddy aspect. There is no headache nor delirium. He suffers from vertigo when in the erect position. The conjunctivæ are very much injected, the pupils natural. With the exception of a bitter taste, and a sense of unpleasant odour, there is no affection of the special senses."

His position in bed is unconstrained, but he leaves it unassisted, with great difficulty.

His lips are dry; there are sordes on the teeth; the tongue is covered with a thick white fur,—its border and tip are red. There is complete loss of appetite; the thirst is considerable. He passed three stools this morning, after a dose of castor oil. There is neither fulness, resonance, tenderness, nor gurgling of the abdomen. The pulse was 120 of moderate power. There was a little cough, and he had expectorated since his admission about two drachms of mucus, streaked with bright blood. There were no abnormal physical chest signs.

The skin was hot, dry, and spotted. The spots were numerous; some obscure, others well marked. They were of irregular shape; the majority faded; a few disappeared on pressure.

Abrad. Capil: Mist. am. acet. Ju. Bovs.

The notes made on the 9th and 10th days show but little change in his condition. On the 11th day, the spots were observed to be decidedly darker in hue, and less affected by pressure. He moaned much in his sleep, and his tongue was dry in the centre. On the 12th day, there was slight deafness, and the pulse fell from 120 to 108; but the tongue was rather tremulous, and the skin continued, as from the first, hot and dry, and the conjunctivæ much injected.

On the 13th day, a decided improvement took place, the pulse had fallen at the time of the visit to 96; the skin was warm and soft, the complexion clearer, the tongue steady, the conjunctivæ less vascular, and the spots paler. On the following day the pulse again fell to 76, the tongue began to clear, the appetite had partially returned, the conjunctivæ were pale, and of the spots merely a trace remained, in the form of a brownish stain; but, at the same time, the deafness increased. This, however, disappeared in about three days, and his appetite was so good that he was placed on convalescent diet. He continued to gain strength for ten days, when he was suddenly seized with rigors, vomiting, &c.; and in three days an eruption of small-pox pustules appeared. He was removed into the Small-pox Hospital. Had the disease in the confluent form, and died in about eight days.

Through the kindness of the medical officers of the Institution, I was permitted to examine the body. It is sufficient to observe that the intestinal canal and mesentery glands were quite free from any trace of lesion. The agminated glands were carefully examined, and I am certain no remains of cicatrization could have escaped observation.

Case 4.—After exposure to the contagion of fever, accompanied with mulberry rash, and without lesion of Peyer's patches, as proved by examination after death:

Ensued, Headache—Pain in the limbs—Delirium—Somewhat relaxed bowels—Absence of abdominal signs—Quick pulse—Mulberry rash—Deafness on the 15th day—Convalescence on the 16th day.

Thomas B., aged 6, a moderately stout fair child, was admitted into the London Fever Hospital April 30th, 1849, under the care of Dr. Tweedie.

His mother, brother, and the nurse of his mother, were all received into the hospital the same week, and all had the mulberry rash.

His present illness commenced on the 20th of April, with headache and pain in the limbs. Delirium was observed on the eighth day of the disease. His bowels were relaxed (from medicine?) for the four days preceding his entrance into the hospital.

The following notes were made when I first saw him on

The 11th day of disease.—He is very delirious, screaming and crying. He says, that he has no pain in his head. The complexion is thick, and there is a mottled appearance of the face, as if from eruption seen through the cuticle. There is no running from the eyes nor nose. He can just stand alone, but staggers a little. His tongue is slightly furred, and dry in the centre. He has passed no stool since his admission this morning. There is no appetite, and but little thirst. The abdomen is free from pain, tenderness, or gurgling. The pulse is 120; rather weak; there is no cough, and no abnormal physical chest signs.

The skin is warm and dry. The trunk and extremities are covered with roundish dusky red spots, not elevated above the surrounding skin, which fade on pressure, and an abundant subcuticular rash. There are no miliary vesicles.

Mist: Am: Acet: Jus. Bov.

The delirium continued the two following days, and he passed restless nights. The mulberry rash was much paler on the fifteenth day; there was a little appetite, and, on the same day, slight deafness was observed for the first time. The tongue dry and brown in the centre on the fourteenth day, was moist and clean on the fifteenth. The bowels acted twice daily; the stools were not watery. The pulse continued 120 till the sixteenth day of disease, when the following note marked his convalescence.

Pulse 96. He slept well; tongue is moist and clean; appetite returning; one stool; no abnormal abdominal signs; skin cool, soft. Spots *scarcely* visible.

I would here direct the reader's particular attention to a few points connected with the four cases above detailed.

1st. The ages of the patients were, respectively, 70, 49, 26, and 6 years; *i. e.*, there was about 20 years' difference in the ages of each of the four cases.

2ndly. Each case was clearly and indisputably traceable to contagion as a highly probable exciting cause.

3rd. These cases agree with each other, and with those from which they caught the disease, in the presence of the diagnostic symptom, *i. e.* the mulberry rash, and in the absence of the anatomical character of typhoid fever, *i. e.* of lesion of Peyer's patches, and enlargement of the mesenteric glands.

4th. These four cases further agree with each other in the duration of the disease under which they laboured.

5th. The two patients who died during the course of the fever, offered no lesion after death to account for the fatal termination; the patient who fell a victim to small-pox, presented no trace of lesion referable to the fever; and the child who recovered, exhibited no symptom that could lead us to suppose that any one organ suffered in such a manner, as that if the child had died, serious structural change would have been seen on examination of the body after death.

[To be continued.]

REPORTS OF SOCIETIES.

WESTMINSTER MEDICAL SOCIETY.

NOVEMBER 3, 1849.

F. HIRD, Esq., President.

Dr. WILLIAM RYAN, exhibited.

CASE OF LARGE HYDROCELE WITH THICKENED SAC.

In the lower part of which is a circular opening, of four and a half inches in circumference, with a well defined thickened edge, from which a prolongation of membrane appears, filled with fluid, and continuous with the general cavity.

The patient, aged 47, five years ago was thrown off a ladder, and in the fall the testis came forcibly on the edge of a cask. He did not experience very severe pain at the time, but had a sensation as if the gland had been quite broken or flattened, and, in the course of half an hour "felt as well as ever," working the remainder of the day. In a few days the scrotum began to swell to about the size of a large egg; remained so a month, and then got smaller. Subsequently it began again to swell, and gradually increased to the present size. It is still increasing. About twelve months after the accident he noticed a second swelling of about the size of a nut proceeding from the larger one, which has, at present, attained the size of the large section of a turkey egg. This has all the appearance of a fold of intestine bulging out; it feels quite soft, and the membrane enclosing it forms quite a contrast with the strong and thickened membrane of the other part of the hydrocele. The tumour now measures 15 inches by 17. It imparts a sensation of fluctuation; there is insensibility to pressure, unless in the back part, in the situation of the testis; no transparency, and no impulse on coughing; the chord seems free. Dr. Ryan observed, that in general, hematocele supervenes on hydrocele; but here there has been no operation which might account for blood being thrown out, nor has there been rupture of the hydrocele at an advanced period. If blood have been poured out, it must have been at the period of the original accident. The diagnosis, as regards hernia or diseased testicle, is much aided by the peculiarity of the case. By pushing up the smaller tumour (a thumb and two fingers can easily enter the opening) the thumb enters the tunica vaginalis by a distinct circular opening of four and a half inches in circumference, with a well defined margin, through which the fluid passes as a continuation of that within the tunica, and contained as it were within a thin bag prolonged from the edge of the opening, and giving it the appearance of a second tumour starting out from the larger. The thumb is not resisted by any obstruction, but feels as if in the centre of a quantity of fluid free from coagula.

The thickened walls of the tunica can thus also be felt between the thumb and the fingers; the testis also distinctly felt from within, which could from the outside be but very imperfectly defined. It would in this case appear as if the reflexed layer of the tunica vaginalis had been burst at the time of the original accident; and that, before the reparative process could have been completed, fluid was poured out, and pushed before it the reparative distensible layer of plastic lymph already thrown out, and so had, up to the present time, kept gradually distending it.

(Since exhibiting the above case to the Society, Dr. Ryan has operated on the hydrocele in company with Mr. Nunn, and drawn away one quart and about an ounce of limpid fluid, without any admixture of blood.)

CHLOROFORM IN MIDWIFERY.

Mr. Greenhalgh opened the adjourned discussion, by briefly stating the results of thirty-two cases which had fallen under his own observation, not one of whom had since suffered from disease of the heart, brain, or lungs, or had been subject to local congestions of any kind. In three cases the forceps were applied; of these, one died five days after delivery from puerperal fever,—all the children were born alive; in one case turning was had recourse to, and the child was still-born; the remaining twenty-eight cases were natural labours. No hæmorrhage occurred in any case; neither was there any delay or difficulty in the expulsion of the placenta. Two suffered severely from intense headaches for some hours after delivery, one of whom had been subject to severe hysterical pains in the head for some years previously. In no case did any permanent ill effects result. The largest amount of chloroform given was 2½ ounces over a space of nine hours; this, also, was the longest period of inhalation, the shortest being seven minutes, the average about two hours. The respective ages of the women were 5—26, 5—30, 3—32, 3—34, 2—22, 2—27, 2—31, 2—38, 1—20, 1—23, 1—24, 1—25, 1—29, 1—33, 1—35, and 1—50; 13 were in their second labour, 7 in their first, 3 their fourth, 3 her sixth, 2 her third, 2 their eighth, 1 their seventh, and 1 their ninth; 8 were of the sanguine temperament; 7 of the nervous; the remainder of a mixed kind; 3 were very stout; 2 very thin; 5, although desirous of inhaling this remedy, commenced to breathe it in a highly nervous state, which greatly retarded its action. All the patients had arrived at the full period of utero-gestation. Mr. Greenhalgh having briefly detailed the particulars of the forceps and turning cases, and given a short account of its effects upon the patient during labour, proceeded to draw the following deductions:—1st. That young children appear to be more susceptible of its influence than those of more advanced age; 2nd. That females are more susceptible of its influence than males; 3rd. That the temperaments possess but slightly modifying influences, except in the highly hysterical diathesis, in which, not infrequently, the most violent excitement is produced, ending in a train of distressing nervous symptoms; 4th. That drunkards, as a general rule, require a larger dose than those of more sober habits; and 5th. That lascivious dreams and remarks are of very rare occurrence, the Author of these observations having met only two out of a large number of cases, in which chloroform had been given for various purposes. Mr. Greenhalgh concluded by stating, that, although chloroform is a very powerful and dangerous remedy, occasionally producing very alarming, nay, fatal effects, yet, if the cases be well selected, the anæsthetic be slowly and cautiously administered, and its effects properly watched, it may be given advantageously either in natural or instrumental labours.

Dr. Henry Bennet had used chloroform extensively in disturbed labours, in operative cases, and also less often for relief in excessive pain. He had found it regulate the contractions of the womb, and quiet irregular action. In cases indicating venesection, &c., he now gives chloroform with universal success, as it allows the ganglionic influences to go on undisturbed. It lessens the irritability of the uterus in turning, and relaxes the soft parts. He referred to Dr. Simpson's experiments recently made on parturition, where the spinal influence had been cut off, as corroborating the value of chloroform. In simple cases he does not give it, unless the fear of pain induces the patient to request it. He considers it infinitely more safe in parturition than in surgical cases. In one case, after inhalation, the uterus relaxed under the binder, causing hæmorrhage, but this accident he attributed to an existing heart disease, and not to the chloroform. He had given it very often in uterine diseases, to obtain more easily the means of examining the case, and where the disease produces great neuralgic pain; also, instead of an opiate, after operations. He had never seen any erotic effects produced, even when he gives it to allay the irritation from enlarged clitoris. In inhaling it a great accumulation of ideas pass through the mind just as insensibility begins. He had given it internally, but found it uncertain.

Mr. Barlow conceived that parturition was more painful than surgical operations, and, therefore, the use of anæsthetics desirable. Unfavourable cases ought to be most minutely detailed to arrive at a proper knowledge of the action of chloroform.

Mr. Gream had heard no new argument in Dr. Murphy's paper, and retained his former objections. He contended, with Dr. Joseph Clarke, that protracted pain in labour does not cause death. Why did Dr. Murphy not quote Collin's, Montgomery, Meigs, &c.? He supposed only because practitioners in large cities, except in one, did not use anæsthetics in midwifery. The results of the practice in Edinburgh showed a great increase in operative cases beyond that met with by most practitioners. If a parturient woman is rendered insensible by chloroform just at the close of her labour, she would recollect nothing of it, the same as if seized with puerperal convulsions.

Dr. Webster detailed three cases in which insanity followed immediately after the use of chloroform in labour; all the cases ultimately recovered. He also referred to the bubbles of air found in the blood in some patients which had died from the use of ether or chloroform.

Dr. Murphy, in reply, had brought forward only facts, and had only referred to those writers who state facts. The Academy of Medicine at Paris had considered the question of bubbles in the blood, but could trace no connexion in it with the anæsthetic. Some constitutions may not bear chloroform; it is, therefore, very necessary to find out what these are. He narrated a case in point, in which a lady was seriously affected by merely rubbing chloroform on her cheek.

MEDICAL SOCIETY OF LONDON.—

OCTOBER 22, 1849.

H. HANCOCK, Esq., President.

CHOLERA AT ALNWICK.

Mr. Dunn read a letter he had received from Mr. Davidson, detailing the sudden outbreak of cholera at Alnwick, in Northumberland. The disease appeared first on the 23rd of September, at three o'clock in the morning, and before 10, a.m., no less than 100 cases had occurred. The great majority of cases occurred in narrow lanes, in which slaughter-houses and open sewers abounded, and where the sanitary condition of the people had been grossly neglected. In one place there were found no less than 147 persons occupying fifteen rooms; they were turned out and the houses cleaned. The writer stated that he had seen some cases in which no premonitory symptoms had occurred. When called to these, he found them speedily pass into a state of asphyxia, from which they rarely recovered. Water had nothing whatever to do with the outbreak or propagation of the disease. The opinion of the writer is, that low, ill ventilated, and badly-drained places, inhabited by the poor, are those which are especially attacked. Filth alone, however, does not generate cholera; but a certain state of the atmosphere is requisite in order that the disease may be developed. At this time diarrhœa prevailed to such an extent that the writer carried with him pills composed of acetate of lead and opium in order to administer speedy relief to those who were affected. Consecutive fever, in some cases, preceded death.

After an uninteresting conversation between Messrs. Dendy, Dunn, and Crisp, and some remarks on the mode of treating cholera, the

President called on Mr. Linnecar to read a paper in reference to a preparation on the table :—

FUNGOID DISEASE OF THE KIDNEY.

The subject of this case was a boy aged two years and ten months. Until twelve months old, he enjoyed uninterrupted good health, with this peculiarity, that the renal secretion was remarkably scanty. In the course of the following six months, he suffered twice from convulsions, which, at the time, were supposed to arise from dentition. Once it was remarked, that he passed a much smaller quantity of urine than was usual with children of his age. In March last, he had an attack of tertian ague, which was easily overcome, but soon after this, the cervical glands were found to be indurated and enlarged, and the superficial veins of the head and neck were peculiarly distinct. His complexion, before somewhat rosy, became pale, and his skin loose. He evinced less disposition to join in play with the other children, and appeared fatigued with little exercise. He had restless nights, and his eyes were sunken: but, as he appeared to enjoy his food, no particular alarm was excited, until near the end of July, when the mother's fears were aroused by the discovery that the lower part of the right side of the abdomen was not only tumid, but firm, and resisting on the application of the hand. Mr. Linnecar now saw him for the first time; he found the whole of the abdomen enlarged; there was dulness on percussion throughout the right half, and extending a little to the left of the mesial line, above and below the umbilicus, the only exception to this being that a sulcus existed on the right side, in a line with the navel, which at first suggested the idea of two tumours. The upper portion, or what appeared to be the upper tumour, stood forward more prominently than any other part, and presented to the eye the size and shape of an ordinary lemon. It was in close apposition with the liver, and was at first supposed to involve the substance of that organ. Passing the hand backwards and in the course of the swelling, it was found to be continued as far as the vertebral column. The lower portion of the tumour occupied the whole of the right iliac fossa pushing upwards and to the left the small intestines. Above, it appeared to commence about half an inch below the umbilicus, and to pass backwards to the vertebral column. The tumour had not a perfectly smooth feel when first examined, but rather a nodulated one, as if made up of a number of smaller bodies. The child was somewhat emaciated, and his complexion pale; the superficial veins of the abdomen, chest, neck, and head, were large and well marked. Pressure on the affected part did not induce pain, and he appeared, when restless, to derive comfort from gentle friction over this part with the hand. He ate freely, and his bowels were in good order. In the month of August he was seen by a physician of eminence, whose opinion was, that the tumour was made up of acephalocysts. To soothe and support the system appeared to be the only indications in his case, and, with that view, fomentations and poultices were applied, vegetable tonics prescribed, opiates were given occasionally, and aperients as circumstances required. On the 5th of September, he was seen by Mr. Hilton, who at once strongly suspected the disease to be fungoid affection of the right kidney. After this his bowels became unsettled, he had a troublesome cough, and, a few days before he died, blood, clotted and diffused through the urine, was discharged from the bladder. On the day of his death he appeared more quiet and comfortable, until about seven o'clock in the evening, when he was seized with convulsions, which terminated his existence in about an hour and three quarters.

The body was inspected sixteen hours after death. It was much emaciated, and the superficial veins of the abdomen, chest, neck, and head, were very distinct. The abdomen was tumid, firm, and dull, on percussion, throughout the right half; the same firmness and the same dulness extended a little to the left of the mesial line above and below the umbilicus; there was resonance, on percussion, in the left hypochondriac and iliac regions. The lower extremities were œdematous, the left more swollen than the right. The lower ribs stood forwards and outwards on both sides; the abdominal wall was very thin; there was very little effusion into the cavity of the peritoneum; omentum destitute of fat. The whole right half of the abdominal cavity was occupied by a firm elastic tumour, which extended about two inches to the left of the mesial line above the umbilicus, and a little more than this below that point; pushing the stomach outwards superiorly, and the small intestines inferiorly. This tumour was separated into two portions by a deep sulcus about 1½ inch in depth, along which ran a considerable vein. At its upper extremity it was firmly adherent to the whole under surface of the right lobe of the liver; and, to the lower portion of the mass, the ascending colon, and about two-thirds of the transverse portion of that bowel was closely united; the vermiform process hanging loose. On passing the hand between the abdominal parietes and the tumour, it was led by the latter to the vertebral column posteriorly; to the diaphragm and under surface of the liver superiorly; and below, across the right iliac fossa and hypogastrium. It had formed no attachment to the small intestines or to the urinary bladder. The right and left lungs were perfectly free in the cavity of the chest, but studded with deposits of a substance in all respects resembling the substance of the diseased mass in the abdomen; heart, pericardium, and pleura perfectly healthy. The right lobe of the liver contained a morbid deposit of the size of an almond, and of a character corresponding with that found elsewhere. The mesenteric glands were loaded with the same substance; the other viscera were healthy. The tumour, on being detached and removed, weighed 5¼ lbs. Left kidney and vessels normal. The whole of the diseased mass was handed over to Mr. Hilton, who found the fungoid disease confined to the cortical portion of the organ; and, although of such large dimensions, the whole mass was found covered by the original investment of the kidney. Two small renal arteries existed—the renal vein was not large—the ureter somewhat dilated, and into one of the infundibular expansions of the kidney, there was projecting, about three-fourths of an inch in length, a portion of the fungoid disease, which explained the appearance of the blood in the urine a short time before death.

Mr. Hilton: I have not examined the tumour very minutely, but I have no doubt of its being a medullary fungoid disease of the right kidney, affecting more particularly the cortical portion of the organ. Mr. Linnecar in his statement has not done himself justice in reference to the diagnosis. When I was requested to see the patient, in consultation with Mr. Linnecar and his partner, some doubt existed in their minds as to whether it was really a case of hydatid tumour, their inclination being, upon the whole, against such an opinion; and after a careful examination I coincided with that view of the case, and came to the conclusion that the swelling was fungoid disease of the kidney. The chief circumstances which led me to such a conclusion were, that the general aspect of the patient strongly resembled what I had previously seen in cases of fungoid kidney; the position of a part of the swelling was in the lumbar region, a portion of it could be detected on making deep pressure in the loin between the last rib and the iliac crest, which was continuous with the projecting mass in front. In addition, an important fact presented itself to complete the diagnosis, on which I placed great reliance in this and the previous cases I had seen—*a portion of intestine (ascending colon) had been recognised, by percussion, lying vertically in front of the tumour, and attached to it.* No distinct fluctuation could be discovered in the swelling, but it had the very yielding elastic character of a fungoid tumour; it did not convey to my fingers the sensation which I have always experienced, when examining, by percussion, a tense hydatid tumour, namely, an evident sharp vibratile thrill: there is, usually, a distinct fluctuation to be felt over the hydatid tumour. In the case before the Society, there was not any blood in the urine, until shortly before death; it generally happens that a portion of the fungoid mass enters the ureter by ulceration, and there bleeds more or less, giving rise to the existence of some blood in the urine (a). When I saw this patient, I expressed my belief that he had fungoid disease disseminated through his lungs. I considered that to be his condition, not only from the pulmonory symptoms, which he then presented, but from having before observed, in several instances, that the lungs are the organs most frequently and early implicated next in succession, when the primary malignant disease is located in the kidneys; this order of succession in the development of the same disease appears to be due to the stream of venous blood having transported the germs of the disease into the capillaries of the lungs, and there inducing, by inoculation, the same disease in the pulmonary tissues;—thence the seeds of disease having once entered the aortic circulation may become more widely distributed, and the same disease may spring up in many and various parts of the body simultaneously.

(a) Since the discussion on this case, Mr. Hilton has examined the pelvis of the kidney, and found a small finger-like piece of the malignant disease projecting into it, which explains the appearance of blood in the urine shortly before death.

Mr. Headland thought that the convulsions were not referrable to teething, but to the daily development of the morbid growth. He was surprised to hear it stated that the urine was healthy. In his opinion, elimination of phosphates is concurrent with disease of the kidney.

Mr. Hilton: My experience does not lead me to such a conclusion. Had I found phosphatic urine, it would not, to my mind, have contributed any evidence that it was fungoid disease, and Mr. Linnecar stated, that the secretion of urine, at the time I saw the patient, was perfectly healthy in every respect except as to quantity; it is quite possible that the deficient secretion of urine may have been the cause of the head symptoms.

Dr. Crisp was surprised at the statement in reference to the urine. In this case there was one healthy kidney, and nature having a compensative power, the secretion was normal. The phosphates in it could not have existed to any extent without having been noticed, and he differed from Mr. Hilton as to the manner in which this disease was carried from the kidney to the lungs.

Mr. Linnecar said, great attention was paid to the excretions, from there being a difference of opinion as to the real nature of the disease. The urine was carefully examined from time to time; its specific gravity was 1000. It contained nothing more than the normal contents of healthy urine till a few days before death, when its specific gravity rose to 1012; there were no deposits. He was not aware till now that phosphatic urine was a sign of disease of the kidney. He should consider albuminous urine more to be relied on. The convulsions were attributable to teething.

After an animated discussion on the mode in which disease is transmitted from one part of the system to another, and on the deposits in the urine in depressing diseases, the meeting adjourned.

NOVEMBER 5, 1849.

Dr. WALLER, Vice-President, in the Chair.

Mr. Pilcher, in renewing the discussion on cholera from the previous evening, remarked that he considered the disease to arise from the malaria generated by decomposing animal and vegetable matters, and to obey the laws of malarious diseases —laws which at present, perhaps, are not yet made out. He did not believe that it was produced by any special trade, although some, perhaps, might cause a predisposition to its outbreak. The dozens of cases at Herne Bay, as mentioned by Mr. Hunt, were produced in precisely the same way as were hundreds at Berlin; in a quarter of that city where it raged most violently, every house was affected, nine out of ten of the inhabitants were seized, and a large majority of those taken ill died. The whole of the drains in this part poured their contents into one vast reservoir—a fact which was not known till an inspector pointed it out. The men living there were employed in making a canal, and they often slept out in the open air, and frequently in wet clothes, returning home occasionally only. Of these only 4 per cent. were attacked, and the majority recovered; of their families, from 70 to 90 per cent were attacked, and a great many died. The men were only occasionally exposed to the malarious influence. They certainly lived better than their families while they were at work, but still they suffered extreme hardships and considerable privations. Special trades had not much influence in the production of the disease except as predisposing causes, and obliging men to reside in malarious districts.

Dr. Crisp remarked, that the persons whose occupations exposed them to the emanations from dead animal matter, were peculiarly exempt from the disease; that only 17 Medical men, out of 2,670 in London had died, and no medical students.

Mr. Hunt agreed that bad drainage was very injurious.

Mr. Clarke did not consider that bad drainage would induce cholera, but when the disease was present it would greatly assist its propagation.

Dr. Willshire thought there was more truth in the facts connected with cholera, than in the theories which had been based on these facts. The disease broke out in 1817 at Jessore, in the jungle of the Delta on the low level, crossed over the table lands of the Himalaya, passed into the interior of India, over the sandy plains of Arabia, through Russia into Europe, breaking out in different places at all seasons of the year, and in all geographical, geological, and climatorial conditions, and under different degrees of solar light and heat. The cholera, on this occasion, made its appearance in London, during the warmth of our summer; in 1832 it broke out in winter. In the most philosophical Papers that had been published, those of Ross in the *Medical Times*, the disease was referred to two subsidiary causes, level and drainage. When there occurs an irruption of the disease, and the cases are severe, it depends on a low level and a bad drainage. A difference in the magnetic intensity of the earth's surface, was at one time supposed to have influence in causing the disease, but this was disproved by the Royal Academy at St. Petersburgh. The absence of ozone had also been brought forward as a predisposing cause; but of the absolute existence of this there is no proof. He would ask Mr. Hunt, if the presence of effete animal matter was a cause of the disease, how he would explain its outbreak among troops on the march, in parts of India and Ceylon, where there were no other human inhabitants than those troops?

Mr. Hunt had not mentioned that as the sole cause, but he considered, that when bad drainage did so act, it was because it contained human excrement.

Dr. Willshire was of opinion, that vegetable organic remains had a great deal to do with the propagation of the disease.

Some further remarks, on the malarious origin of the disease, were offered by Mr. Pilcher, Dr. Crisp, and Mr. Roberts, after which Mr. Pilcher described a case of obstruction of the colon by a plum-stone, and exhibited the parts engaged in the disease.

The patient was an old and valued servant of his brother's, about 56 years of age. Had been labouring under constipation of the bowels, with distended abdomen and occasional vomiting, for three days; had taken drastic purgations, but without effect. There was a tumour in the right side of the abdomen, which was diminished in size by pressure, and moveable to some extent. The application of leeches had been attended with some relief. A careful examination proved the non-existence of hernia. Small doses of blue pill and extract of henbane were ordered, and then succeeded by injections, which were also ineffectual in procuring relief. An injection was then given through the large tube of the stomach-pump pressed up into the colon; but without producing the slightest advantage, and the patient died on the sixth day. The body was examined the same evening. The intestines were found to be greatly distended, with some signs of inflammation. In the transverse arch of the colon there were two or three ulcerations, not penetrating into the peritoneal cavity, being closed by the omentum. Embedded in one of these was a plum-stone, lying in an artificial pouch, as it were. The mucous membrane of the lower part of the ileum was extensively ulcerated. The ileo-coecal valve healthy, as was also the remaining portion of the intestines. The history of the case showed, that six weeks previously she became very poorly after eating freely of plum-tart, of which she was very fond. She had an attack of constipation, which was retarded by the measures which were adopted at the time, but relieved occasionally afterwards. It was a question, whether the presence of the plum-stone was the original cause of the disease, or whether the intestine had been previously constricted, and thus arrested the progress of the stone. She had not, previously, exhibited signs of disease. Did the stone, in its attempts to pass through the ileo-coecal valve, cause the ulceration of the mucous membrane of the ileum?

The preparation was exhibited.

Notice was then given, that on the 3rd of December a special meeting would be held, to consider the propriety of removing the Society from Bolt-court, of changing the day of meeting, and further of electing the President for one year only.

The meeting then adjourned.

REGISTRAR-GENERAL'S QUARTERLY RETURN, TO SEPTEMBER, 1849.

Having carefully considered this document, we proceed to present our readers with an analysis of its contents, in which we have endeavoured to keep in view all those points of interest to the Profession from which may flow practical benefits.

The general results are as follow:—

The marriages are a little above the average, the births slightly below the average, the deaths in greater number than have ever before been registered. The deaths in the three months were 135,364, or 47,602 more than were registered in the summer quarter of 1848. They exceeded the births (135,200) by 164; and as the emigrants in the quarter from London, Liverpool, and Plymouth alone, amounted, according to the Emigration Commissioners, to 46,558, the population of England has suffered, during that period to an extent of which there is no example in the present century.

I. To begin with

London.—The deaths were 27,109, and exceeded the births (17,224) by 9,885. The deaths by diseases of the zymotic class were 17,763; by other diseases, 9,287; the causes of 59 deaths were unspecified; only 78 deaths from small-pox, and 274 from measles were registered, 428 from hooping-cough, 386 from scarlatina. Scarlatina suddenly subsided. Of typhus, 710 persons died. The co-existence of influenza and cholera as epidemics appears never to have been witnessed.

The course of the cholera in London has been already detailed in our Journal; we therefore omit further reference to it here.

The deaths from all causes were 3,183, or about three times the average number, in the first week of September; and 27,109, or double the average, in the thirteen weeks of the quarter. The mortality from cholera varied in different districts of the metropolis from 8 to 239 in 10,000; and was greatest in the low, the worst drained, the poorest districts; the districts supplied with water from the Thames between Waterloo-bridge and Battersea New Town.

II. South-Eastern Division.—The epidemic extended in *Surrey* up the Thames to Richmond and through Mitcham, south of Wandsworth, to Croydon; Epsom and the districts on and south of the Surrey hills partially escaped. Farnham was healthy, notwithstanding bad drainage, and immigration of many strangers of the poorest class to it during the hop-picking. In *Kent*, the districts on the Thames, the Medway, and coast from Gravesend, Milton, Rochester, and Chatham, to the Isle of Thanet, including Margate and Ramsgate, suffered severely. The deaths in Gravesend are on an average plast quarter, however, 193 were by cholera The, mortality of Margate, Ramsgate, the Isle of Thanet, and Hastings was more than double the average; in Brighton the mortality was little less than in those just mentioned. Maidstone on the Medway suffered. In the Isle of Grain (Hoo), Folkstone, and in several districts in the interior of Kent and Sussex, the mortality was below, or not above the average. *Berkshire.*—The deaths in Windsor, Wokingham, Reading, Bradfield, Wallingford, and Abingdon were somewhat above the average. The mortality was low in Wantage and Faringdon. *Hampshire.*—The deaths in Portsea Island, including Portsmouth, were about three times the average. The island, says Mr. Martin, is not two feet above high-water mark, and parts are below; the drainage . . . . The mortality was double the average in the Isle of Wight. Many districts of Hampshire were unusually healthy.

III. South Midland Division.—*Middlesex.*—Brentford, Staines, Edmonton, and Barnet had many deaths; but the other districts suffered less. *Hertfordshire.*—Royston and Hitchin, also Ware and Hertford on the Lea, and where the New River has its source, as also Watford on the railway, suffered severely. *Buckinghamshire.*—Great Marlow and High Wycombe suffered. The other districts, except Eton, were unusually healthy. *Oxfordshire.*—In Oxford, 89 persons died from cholera; but no deaths occurred in 6 parishes where the streets are wide and clean. The other districts were healthy, except Headington, Witney, and Banbury. *Northamptonshire.*—Northampton has been affected by cholera; but the rest of the county, as well as *Huntingdonshire* and *Bedfordshire*, have been healthy. *Cambridgeshire.*—In the Wisbeach sub-district, and in North Witchford, many cases. Both districts are on the coast side of the Isle of Ely. Cambridge and several remaining districts have been healthy.

IV. Eastern Division.—*Essex.*—In West Ham and Romford the deaths were double the average, and rife in Rochford, north of the Thames, at its mouth; and in Tendring, extending north to the Stour, the mortality was high. In Harwich the births were 28, the deaths 111. The other more rural districts were healthy, except Dunmow. *Suffolk.*—Ipswich, generally unhealthy, had 241 deaths, or somewhat above the average number; a few from cholera. In Plomesgate and Blything, on the the mortality was slightly above the average. coast, and at Stow and Cosford in the interior. *Norfolk.*—In Yarmouth, Norwich, and Depwade, the two first connected by the navigable river Yare, the mortality was sensibly above the average. At Yarmouth, the mortality was not double the average. The rest of the coast of Norfolk suffered nothing; and many of the districts unusually healthy.

V. South-Western Division.—*Wiltshire* has presented great contrasts. Highworth, Cricklade, Malmesbury, and Marlborough, healthy; so have Pewsey and Amesbury; as well as Tisbury and Mere on the borders of Dorsetshire. Chippenham, Calne, Devizes, Melksham, Bradford, and Salisbury, had an excess of deaths. Salisbury is always an unhealthy place; the courts and alleys are always in a filthy state. The surrounding districts of Wilton and Alderbury suffered much. The Avon flows from Salisbury through Fordingbridge, Ringwood, and Christchurch to the sea. Fordingbridge was infected; Ringwood lower down the river, and Christchurch on the sea, as well as Lymington, were unusually healthy. *Dorsetshire.*—With few exceptions the health of the districts of the interior was above the average. *Devonshire.*—The mortality has been higher than the average in the districts on the south coast; Exeter has suffered lightly. In Newton Abbot, on the Teign, the deaths were nearly doubled. In Plymouth and the adjoining districts, the mortality was more than three times the average of the season. The mortality was below the average rate in the districts of Central and of North Devon, except in Barnstaple, on the west coast. Scarlatina, diarrhœa, and cholera, were prevalent in the lower parts of Ilfracombe, a healthy place, but a port over against Swansea and Neath, where cholera was excessively fatal. *Cornwall.*—In St. Germans, next Plymouth and the estuary of the Tamar, the deaths from all causes were five times the average. In the little fishing town of Kingsand 93 died out of a population of 789. In Liskeard the mortality was doubled. In St. Austell the deaths nearly tripled. In the Mevagissey sub-district the births were 16, the deaths 140, in a population of 5218. Truro, and Falmouth, and Redruth, were also attacked, but the deaths were not raised more than 50 per cent. Helston, Penzance, and the Scilly Islands, with Launceston, Camelford, and Stratton, were exceedingly healthy. *Somersetshire.*—The mortality below the average in several districts of Somersetshire; but Bridgewater suffered to some extent, so did Wells, Shepton Mallet, and Clutton. In Keynsham and Bath, on the Avon, the mortality was raised about 50 per cent. by cholera; in Bedminster, separated from Bristol by the Avon, the deaths were tripled.

VI. West Midland Division.—*Gloucestershire.*—Bristol and Clifton suffered severely. Cholera raged in the Poor Asylum, Stapleton. The mortality of Tewkesbury was doubled by cholera. In *Herefordshire* and in *Worcestershire* the general mortality is not above the average. Cholera raised the mortality in Stourbridge and in Kingswinford. *Shropshire.*—The mortality of Shrewsbury was double the average. The disease reached Welshpool, in Montgomery, where the Severn ceases to be navigable. A few cases in other districts of Shropshire. *Staffordshire.*—Newcastle-under-Lyme suffered severely. This town is on some of the highest ground in the interior of England. It is in a basin, and the Lyme, made the

open sewer, running through the town, is dammed up by a mill, and sends up from its polluted, black puddly bed poisonous exhalations. Stafford, Leek, Cheadle, Uttoxeter, Burton-upon-Trent, Tamworth, and Penkridge were as healthy as usual. Wolverhampton was one of the great stations of cholera; the deaths were three times the average number. In Bilston, one of the sub-districts, the deaths registered were 671. Kinfare was very healthy. In Walsall and West Bromwich the deaths were less than double the average. In Dudley the mortality of the whole district was not above the average. *Warwickshire.*—The mortality was low in Birmingham; the same in Aston, in Warwick, and the other districts, except Shipton-on-Stour and also Stratford-upon-Avon. Coventry suffered severely, more than double the average. The mortality was somewhat above the average in Foleshill. The sanitary conditions of Coventry are unfavourable.

VII. North Midland Division.—Leicester, and all the other districts of *Leicestershire* (except Market Harborough) and *Rutlandshire*, less than the average mortality, (the several Registers in Leicestershire attribute the general healthiness to prompt sanitary measures taken by local committees); as also Lincoln, and all the districts of *Lincolnshire*, except Gainsborough, where cholera raged with violence. Gainsborough is in communication with the port of Hull, on the north side of the Humber. In Glanford Brigg, opposite Hull, the mortality was one-fourth above the average; and there were some deaths from cholera, as there were in Boston, the only seaport town, except Grimsby, on the long coast of Lincolnshire. Nottingham, on the Trent, and all the districts of *Nottinghamshire* have been comparatively healthy, except East Retford. The districts of *Derbyshire* were unusually healthy.

VIII. North-Western Division.—Nantwich and Runcorn, in *Cheshire*, suffered from cholera; Stockport, especially Heaton Norris, and the town sub-districts, lost several lives by cholera; some of the sub-districts were unusually healthy. Cholera prevailed in Chester; in Wirrall, including Birkenhead, and on the south side of the Mersey. *Lancashire.*—Liverpool was one of the chief cholera stations; here it destroyed 3,488 lives. West Derby surrounds Liverpool on the land side; the deaths were, in the quarter, probably 2 per cent. Prescot and Wigan suffered to about half the extent. The deaths in Manchester, Chorlton, and Salford, were rather more than 1 per cent. Warrington and Ormskirk, on the west coast, suffered from the epidemic, but not severely. Bolton, Bury and Worsley, Ashton, Oldham, Rochdale, Haslingden, Clitheroe, Blackburn, Chorley, in the interior; Fylde, and Garstang, and Ulverstone, on the coast, experienced not more than the usual mortality. Cholera raised the mortality in Preston-on-the-Ribble, and in Lancaster.

IX. Yorkshire.—*West Riding of York.*—In the high lands, at the head of the basin of the Ribble, the deaths were much below the average. Cholera had not prevailed. And the same may be said of Skipton, Settle, Ripon, Knaresborough, Keighley, Todmorden, Saddleworth, and all the districts of the West Riding at the upper part of the great basin of the Ouse. The mortality has been below the average in Halifax, as well as in Huddersfield. The cholera broke out with great violence in some labourers' dwellings on a hill-side at Huddersfield. The Registrar of Huddersfield states some facts, showing the wretched sanitary state of the locality nuisances of all sorts being allowed to exist Kingston, a part of the low Portsea Island, on the south coast, is also remarked upon by the Registrar as being in a bad sanitary condition; and such instances enable us to understand how cholera can be made fatal on open fields, hill sides, and high lands, in the interior of the country. In Leeds the deaths were 1934, the population near 100,000. In the Hunslet sub-district the deaths were 535, about 3 per cent. of the population, and the deaths from cholera were 307. The township is flat, and many parts are as low as the river. Ecclesfield, Wortley, Ecclesall Bierlow, Rotherham, experienced no increase in the mortality though the cholera had visited them. Sheffield was visited severely by the epidemic in 1832-3, and the authorities appear to have efficiently carried out judicious sanitary measures; still it has suffered to some extent, though not severely. Descending the Don and the river Went, through Don[illegible] Thorne to Goole and Selby, cholera [illegible] more fatal, raising, and, in the ports, [illegible] the mortality.

[illegible]—Hull, on the river of that name and [illegible] Humber, was swept by the pestilence; the [illegible]lity was about 3½ per cent. In Hull and Sculcoates the mortality was 3 per cent. in three months.

The deaths in York were at the rate of 4 per cent. per annum of the population, and cholera prevailed there with severity; also in Pocklington and Howden.

North Riding.—The mortality in all the districts of the North Riding, except Scarborough, is naturally low, and in the last summer it was below the average. The ports scarcely suffered.

X. Northern Division.—"Descending to the Tees, and traversing the coal regions of Durham," says the Report, "the shadows of death thicken around us. Barnardcastle, Darlington, Stockton down the Tees, Yarm, and Hartlepool suffered; so did Durham, Chester-le-Street, and Sunderland on the Wear, and Gateshead, south of the Tyne. The mortality of Weardale and Auckland—higher up and round the sources of the Wear—was below the average. The deaths in Newcastle-upon-Tyne, in *Northumberland*, over against Gateshead, were about 1 per cent. of the population; the deaths in Tynemouth, including North Shields, were three times the average. Alnwick on the coast, and Berwick-on-Tweed suffered to a slight extent from the epidemic. Cumberland, generally, enjoyed more than average salubrity. The five western districts on the coast, Carlisle communicating with Newcastle by the railway, Wigton, Cockermouth, Whitehaven, and Bootle have experienced a mortality higher than their average. The Workington sub-district of Cockermouth, on the coast, was attacked by the epidemic at the end of July; the Cockermouth sub-district, higher up the Derwent, much later. *Westmoreland* was healthy. The registrars, in their notes, return "no epidemic."

XI. Welch Division.—Chepstow and Monmouth on the Wye were healthy; Newport, Pontypool, and Abergavenny were ravaged by cholera. "Cholera found lodgment in one of the filthiest streets of the town of Newport" about the middle of May; 19 deaths from this cause were registered in the June quarter; 182 in the last quarter, ending September. The sub-districts of Abergavenny present striking contrasts: in Tredegar there were 157, and in Aberystruth 210 deaths from cholera; in Abergavenny itself only 9. Merthyr Tydfil was one of the great cholera works among the hills. Death is always busy here; but, in the last quarter, 1876 lives were destroyed, viz.: 41 in Gelligaer; 487 in Lower Merthyr Tidfil; 1023 in Upper Merthyr Tydfil; and 325 in Aberdare. The mortality was about 2½ per cent. higher than in some of the worst districts of London. The most populous parts of Merthyr Tidfil are well situated on sloping ground, a very small portion being on a level. The Report here gives a striking instance to what extent the salubrity of a locality may be affected by human interference [illegible] lost in the mining districts is inconceivable." Descending the Taffe to Llandaff and Cardiff, traces of death are seen on every side. In *Carmarthenshire*, the deaths were double their average. *Pembrokeshire*, with its ports and harbours, escaped; a few isolated cases of cholera occurred, in the sub-districts around; others were "unusually healthy." In Cardigan and Newcastle-in-Emlyn, and Tregaron, the mortality did not exceed the average; in Aberayron and Aberystwith it did slightly; *Brecknockshire* suffered; Builth, in the north, was healthy; in Tay the deaths were scarcely above the average; so of *Radnorshire*, as well as Machinlleth in *Montgomeryshire*. Newtown, at the end of the quarter, and Pool, to which the Severn is navigable, in Montgomeryshire, suffered from the epidemic; so did Holywell, in *Flintshire*, on the estuary of the Dee. *Denbighshire*, *Merionethshire*, extending from Cader Idris to Snowdon, were left unscathed by the cholera. In *Carnarvonshire*, the mortality of Conway and Carnarvon was not above the average, but in Bangor and Holyhead, on the road to Ireland, cholera prevailed. The Anglesey district suffered less than the Isle of Wight.

The following is a general summary for London, and so far as Deaths being over Births is a test of unhealthiness, is instructive:—In London, the Deaths are over Births in 55 Districts, by 5,540; and under Births, in 18 Districts, by 435. In the West District they are over in 7, and under in 2 Districts; in the North, over in 5, and under in 7; in the Central, over in 10, under in 5; in the East, over in 15, under in 2; and in the South, over in 18, and under in 3. The 18 Districts in which the Births exceeded the Deaths, are—

West—St. George's, Hanover-square; St. James's, Westminster (Golden-square). *North*—Marylebone (St. Mary); ditto (Christchurch); Hampstead; Pancras (Kentish-town); ditto (Somer's-town); Islington (West); Hackney (Stamford-hill). *Central*—Holborn (St. George the Martyr and St. Andrew, Western); Clerkenwell (Amwell); St. Luke (Old-street); ditto (City-road). *East*—St. George-in-the-East (St. Paul); Stepney (Mile-end Old Town, Upper). *South*—Wandsworth ([illegible]); Lewisham (Plumstead); Lewisham (Sydenham).

With respect to the Country generally, the following appears to be the result. It shows in how many Districts the Deaths were over, and in how many under Births:—

Giving a result of 289 districts in which Deaths were over Births, and 545 where Births were over Deaths; and according to this we have not decreased in general population, at least over one-half of the kingdom, although we have not maintained our rate of increase.

HEALTH OF LONDON DURING THE WEEK ENDING NOV. 10.

The Registrar's Return gives a total of 893 deaths from all causes; an increase of 56 on those of last week; but a decrease on the average of 5 autumns of 269. The particulars as to sex, and the proportion of births to deaths will be seen by our Tables. Zymotic diseases are below the average by 91, occurring principally under the heads small-pox, measles, scarlatina, hooping-cough, cholera, influenza, and typhus. Six deaths only are returned from cholera, being 2 below the average. Under sporadic diseases, the deaths from tubercular diseases are 30 below the average; diseases of the brain, spinal marrow, nerves, and senses, 21 below; diseases of the lungs and other organs of respiration, 71; of the stomach, liver, and other organs of digestion, 24; from age the deaths are below by 15; and from violence, privation, cold, and intemperance, 14. The deaths from atrophy are above the average by 8, the numbers being 26 to 18. The decrease under the head diseases of the lungs and other organs of respiration, is worthy of notice, that decrease taking place principally in pneumonia, which shows a decrease of 26; in asthma, 16; and in bronchitis, 17. No deaths are registered under the heads, ague, infantile fever, noma or canker, hydrophobia, ulcer, fistula, chorea, aneurism, ascites, stricture of intestinal canal, disease of pancreas, hepatitis, ischuria, diabetes, stone, cystitis, paramenia, ovarian dropsy, arthritis, diseases of the skin and cellular tissue, intemperance, privation of food, neglect, and cold, the total average of these being for the 5 autumns, 19·9. Of the 6 deaths by cholera,

1 occurred in the North District, to the daughter of a labourer, aged 1½ residing at Water-lane, Homerton; duration 3 days. House clean and airy. 1 in the East District, (Hackney-road,) a journeyman cordwainer, aged 38, at Weatherhead-gardens, Crabtree-row; duration 2 days; a low and undrained spot, with a porous soil, through which the waste water percolates freely. And 4 in the South districts; 1 in St. Saviour, Southwark (Christchurch) an actress, aged 22, spinster; Boundary-row; duration twenty-two hours. She had drank freely of wine and brandy on the night before her decease, and was intoxicated when the medical man saw her the next morning. 1 in Bermondsey (St. James) a daughter of Officer of Customs, aged 7, cholera biliosa; Drummond-road. 1 in King's-row, Walworth, the wife of a compositor; cholæraic diarrhœa 4 months, anasarca and ascites 2 months; and a female child, aged 1 year and 7 months, cholera, atrophy, in Lambeth. Of the 25 cases of diarrhœa, 5 occurred in the West Districts; 1 in the North; 3 in the Central; 7 in the East; and 9 in the South. The 1 death registered from apoplexy occurred in Huntingdon-street, Hoxton, to a female aged 65, who had lived for 4 years in a cellar 11ft. 4in. long, 9ft. 6in. wide, 5ft. 9in. high, and 5ft. 7in. below the surface of the street, with a small window, and the walls so damp that water might be brushed from them.

The daily reading of the barometer was above 30in. on Thursday, Friday, and Saturday by ·191, ·217, and ·155 respectively. The temperature was plus the average of 7 years on Sunday and Monday, minus on Tuesday, and plus on the other days of the week; in the whole period giving a plus of 4·1. On Thursday the reading was 56·5, being plus 10·3 over the average. No electricity was shown on Sunday, Wednesday, Thursday, Friday, and Saturday; positive and tension strong on the other days.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Nov. 10, 1849.

Causes of Death.	Total.	Average of Five Autumns.
All Causes	893	1162
Specified Causes	888	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	216	307
Sporadic Diseases;

MEDICAL NEWS.

Royal College of Surgeons.—The following gentlemen having undergone the necessary Examinations for the Diploma, were admitted Members of the College, at the meeting of the Court of Examiners on the 9th inst:—Messrs. Alexander Williams, Army; Ralph Holt Kaye, Ratcliff Bridge, Lancashire; John Robinson, Medhurst, Sussex; James Howell, St. Clare, Carmarthenshire; Henry Nuttall, Syston, Leicestershire; Thomas John Warburton, Betley, Staffordshire; George Peat Dunn, Ledbury, Herefordshire; Walter Hook Bolton, Carrickmines, County Dublin; George Fowler Bodington, South Colfield, Warwickshire; and William Bratt, Stratford-on-Avon. At the same meeting of the Court, Mr. William Newman Brake passed his examination for Naval Surgeon. This gentleman had previously been admitted a member of the College, his Diploma bearing date May 16, 1844.

Obituary.—On the 4th inst., at Brinklow, near Coventry, Francis Allcock Oldaker, Esq., surgeon, aged 80.

The Royal Medical and Chirurgical Society.—The first meeting of this society for the present session was held on Tuesday evening, the President, Dr. Addison, in the chair. We have seldom seen a more numerous muster of Fellows and visitors. The room was crowded, and extra seats were of necessity sent for. Among the Fellows present, we noticed Drs. C. J. B. Williams, Locock, Wilson, Baly, Gregory, Webster, Burrows, Bashum, and Sibson; and Messrs. Arnott, Coulson, Fergusson, B. Phillips, Skey, Le Gros Clark, Shaw, Toynbee, C. de Morgan, Curling, Hilton, Wade, and R. Quain. There were upwards of one hundred persons in the room. The ordinary business for the evening included the election to the Fellowship of Drs. Fincham and Gull, and Messrs. White and Hansard. The door-posts were as usual ornamented with framed sheets of foolscap, on one of which were the titles of papers already received for reading. On the other side, the broad sheet gave the names of nine defaulters to the fund,—a proceeding which so rich a Society would do well to dispense with. If a member cannot afford the fee, he had better resign; if he does not, after the lapse of a certain time, the Council should have the power quietly to remove his name from the list of Fellows; but to gibbet him thus *in terrorem*, as it were, like the pirates at Blackwall, lest there should be other *pecuniary offenders*, is neither wise, nor becoming a Society of Professional gentlemen. The paper read at the meeting was—"The History of a Case of a Foreign Body in the Right Bronchus. By John Gregory Forbes, M.R.C.S., Surgeon to the Western General Dispensary." We shall give an abstract of this interesting case next week, and at the same time report the discussion which ensued after it had been read.

Royal Free Hospital.—Dr. Heale has been elected Physician to this Hospital in the room of Dr. Peacock, resigned.

Indian News.—Physician-General Patch has retired from the service. Dr. Burnes, K.H., is now head member of the Medical Board, the second and third being Drs. Sinclair and Montgomery. Dr. Rost, resident surgeon at Bagdad, died on the 19th of June last. In several of the stations much sickness had prevailed. At Wyzerabad upwards of twenty Europeans had been struck down by apoplexy on the 13th of August; at Mooltan almost all the Europeans were suffering from fever. The cold weather was, however, setting in, and the sickness was decreasing.

The Late Dr. A. T. Thomson's Museum.—We understand that the great botanical and pharmaceutical collection of the late Dr. Anthony Todd Thomson has been purchased by the President and Council of Queen's College, Cork. Dr. A. T. Thomson was the able Professor of Materia Medica at University College; and it is a subject of great regret that the directors of that Institution did not think it advisable to append, as an heir-loom to the Chair, the valuable collection of their first Professor, to whose memory a "Thomsonian Museum" would have been no undue monument. The collection, however, has not fallen into unworthy hands. Dr. Fleming, one of the editors of the *Monthly Medical Journal*, is the newly appointed Professor of Materia Medica at Queen's College, Cork, and than whom none can do more justice to the treasures placed at his command.

Cholera.—At the sitting of the Communal Council of Brussels, on the 10th instant, a Report on the progress of cholera in Belgium was read, from which it appeared that the epidemic commenced on the 24th of April, and ceased on the 27th of October. The number of cases amounted to 1244, of which 1013 proved fatal, 931 of these being resident, 17 military, 15 prisoners, and 50 foreigners. Notwithstanding the awful mortality, which was above the rate of 80 per cent., high commendations were passed on the medical men, the officers of police, the sisters of charity, the clergy, &c., for their indefatigable exertions, and it was decided that a medal should be struck, and presented to each individual, as a souvenir of their eminent services. Shall England always be the last in the race of gratitude for such services? Shame on her! her ingratitude is disgraceful to her in every way. France and Prussia have emulated the conduct of Belgium. Here, alone, there are not any honorary rewards for those who exert themselves in the cause of humanity. Poor Walker's widow had a gratuity of 70*l.*; for Lynch's, family the public were appealed to. Our Government do nothing in such cases; not a medal or sign of honour for any of those who risked their lives and those of their families in rendering professional assistance to the sick and dying.

Dr. Brittan.—It is reported that Dr. Brittan, of Bristol, whose discoveries respecting the cholera sporules have been the subject of so much attention of late, has been appointed an inspector by the Board of Health for two months, at a salary of 3*l.* per diem, and travelling expenses. The Board, it is added, has requested him to continue his microscopic inquiries respecting the fungoid origin of cholera. We hear that it is not improbable that he will be gazetted to some permanent appointment in connexion with the public health.

Cholera.—The *Western Times* of Nov. 3, states, that during the previous Friday night, several persons in Union-street and Eastover, Bridgewater, were attacked with cholera, and fifteen of them died in forty-eight hours. Union-street is one of the great strong holds of filth—flat, ill-drained, and surrounded by stagnant ditches.

Alleged Death from Chloroform.—A Coroner's inquest was held at Leeds on the 25th of last month, on the body of Robert Mitchell, who, previously to his death, had a severe attack of delirium tremens, brought on by drinking. The man was attended by Mr. J. Teale, surgeon, who, in consequence of the failure of other remedies to alleviate the disease, caused the patient to inhale chloroform. He was at this time in a furious delirium, and, supposing a neighbour robbing him, ran out of the house to a place at some distance, where he said the thief resided. He was brought back in a coach with Mr.

Teale, who administered chloroform after the patient was placed in bed. A teaspoonful of the anæsthetic was poured on a folded napkin and gradually applied to the nose and mouth. The pulse at first improved, and the patient was perfectly tranquil, but after a short time he became extremely violent. Chloroform was administered a second time, in the same quantity, and with the same results; and in an hour and a half afterwards the patient expired. The jury returned a verdict, that death had been caused by delirium tremens, and that no blame whatever was attached to Mr. Teale. The surgeons who examined the body, were of opinion that the man died under a combination of delirium tremens and the fumes of choloroform.

Re-appearance of the Cholera at Gloucester.—A respectable family in this town has been attacked with cholera during the last week, and four have died. We do not hear, however, that any other persons have been seized.

Chest Diseases Hospital.—A meeting was held last week in the Board-room of the City of London Hospital for Diseases of the Chest, when it was stated, that nearly 4,700 patients had been treated for diseases of the heart and lungs since the opening of the Institution in June, 1848. The Secretary reported the receipt of the munificent donation of 100*l.* from the Earl of Onslow. Dr. J. Risden Bennett was appointed Physician in the vacancy occasioned by the lamentable death of Dr. Allen Williams, and Mr. John Hilton, surgeon, in that occasioned by the resignation of Mr. Erichsen. Dr. Birkett has also been elected Physician, as a requisite addition to the medical staff.

Health of Towns' Act.—At Ilfracombe, Mr. Jones, a surgeon, and at Teignmouth, three other medical men, named Drs. Richards, Bartlett, and Cartwright, have been among the most strenuous opponents of the introduction of the Health of Towns' Act in those places. Such conduct is not common: medical men, generally speaking, are desirous to do all in their power for the prevention of disease. Ilfracombe is said to be in great want of drainage. Mr. Jones met with a worthy coadjutor in his opposition to the scheme for improvement. A voluntary rate of 4d. in the pound having been proposed to effect the drainage, farmer Parkin called out, "I tell'ee how to do it for wan quarter o' the money Jist do' away wi' yer gas, and git an ingin, that'll pump the watter up to the highest mountain about here, and then pour it down over, and that'll wash the town clean enough." The same worthy said, "I consider that avery man that 'eth got a houze, ought to wash 'es own vore door." And to such hands, in some places at least, is the health of Englishmen entrusted!

Fatal Result of French Etiquette.—"Internes," or hospital house-surgeons, are not permitted to operate during the absence of their chiefs. The consequences of this species of etiquette was curiously illustrated a few days since, in a case which has excited considerable discussion. A poor woman died of typhoid fever in the upper wards of the Hôtel Dieu. She was in the 30th or 31st week of her pregnancy, and the heart of the fœtus could be distinctly heard beating, on the application of the stethoscope. As the disease of the patient had occurred during the night, the *interne* on duty immediately applied to the Director of the hospital for permission to operate, and thus endeavour to save the life of the fœtus. The Director refused, on the ground of a standing rule, "which forbids any dresser to operate in the absence of his chief, unless the assistance of a regular doctor can be obtained." The chance of saving a human life was thus sacrificed to a point of etiquette and the strict interpretation of an obsolete rule.

Mesmerism at Rome.—The absence of His Holiness from Rome appears to have offered a vacancy in the art of miracle-mongering, which has been seized upon by the mesmerizers; but their triumph has been of short duration, as might have been easily foreseen. At Rome it is sacrilege for any one, save a priest, to work a miracle. This fact seems to have escaped the sagacity of M. Lafontaine, an authority among the mesmerisers, who recently visited the "holy City," and there opened shop on his own account. At a meeting, attended as we are informed (in letters from Rome) by all the Medical men of eminence in "modern Babylon," M. Lafontaine injected the mesmeric fluid into the ears of two young deaf and dumb persons, who immediately recovered the faculty of hearing! For his pains he received a pressing invitation to betake himself elsewhere, proving the truth of the old adage, that two of a trade can never agree.

French Academies.—We agree with our contemporary, the *Literary Gazette*, that few English readers are acquainted with the constitution of the French Academies, which we avail ourselves of its foreign correspondent to explain. The Academies are five in number, and collectively form what is called "the Institut," that learned body to which Lord Brougham is so proud of belonging, that he always tacks "Membre de l'Institut" to his name on the title-pages of his pamphlets. Each Academy is independent, and has its own separate revenue; but all five have the same agency, secretaryship, library, museums, and collections. The five Academics are—1, The *Académie Française*, consisting of forty members, who are specially charged with the composition of the dictionary of the French language, and with the examination of important works in literature, history, and science; 2, The *Académie des Inscription et Belles Lettres*, consisting of forty members, who occupy themselves with the learned languages, antiquities, monuments, history, and particularly with the translation of Greek, Latin, and Oriental writers whose works may not have been translated into French; 3. The *Académie des Sciences*, of sixty-three members and two secretaries, devoted to the different mathematical and physical sciences; 4. The *Académie des Beaux Arts*, forty members, devoted to painting, sculpture, architecture, engraving, and music; 5. The *Académie des Sciences Morales et Politiques*, thirty members, who occupy themselves with philosophy, morals, legislation, public law, jurisprudence, political economy, statistics, and general history.

Carlisle.—A very important Report on the state of the Asylum at Dunstan Lodge was presented lately to the magistrates sitting in County Sessions at Carlisle. The Committee, after recording that the Asylum was in a very satisfactory state, observed, that their attention was particularly directed to four cases, three of which were of a very serious nature. The first was that of a female, sent from Carlisle, in a high state of fever, which assumed the character of typhus, who was so ill as to require to be carried from the station to the Asylum. She survived her removal only nine days,—death, according to the medical men, being hastened by such removal. The Committee, in speaking of this case, condemn the recklessness of sending a patient under such circumstances by a railway train, thereby running the risk of spreading infection to other passengers, as well as of introducing fever into the Asylum. The iniquity of the proceeding to the poor patient herself might also have been reprehended, with justice, by the Committee. The next case was that of a man, who had been confined to his bed for nearly twelve months previously, from which he was taken to be removed to the Asylum early in last March, (a most unfit time of the year for such a removal,) where he died in fourteen days. The third case was that of a female far advanced in pregnancy, who died on the eighth day after her arrival at the Asylum, having given birth to a dead child the day before. On these cases the Committee remark as follows:—

"Your Committee cannot consider these as fit objects to be sent to an Asylum. There is too much reason to fear that, in all these cases, death was accelerated by the removal; and the cruelty of sending persons, under such extreme circumstances, merits the severest reprehension.

"As your Committee, on a former occasion, felt obliged to notice the great impropriety of removing persons while suffering under severe and acute sickness, they trusted that no repetition of such proceeding would again take place, and that magistrates, as well as medical men, on signing the necessary certificates of admission, would, previously to removal, ascertain, not only the mental, but also the bodily health of the patients.

"The attention of the Visitors, as well as of the Commissioners in Lunacy, having been drawn to these cases, your Committee felt themselves called upon to take some decisive steps to prevent, if possible, a repetition of proceedings so reckless, as well as so needlessly expensive to parishes.

"They, therefore, avail themselves of the present opportunity to make it publicly known to all concerned, by means of this Report, that, in any future case of removal to the Asylum, where the patient is suffering under acute bodily sickness, or disease, which may tend by such removal to cause death, *and such shall take place*,—that they have directed Mr. Wilkinson to call upon the Coroner to hold an inquest on the body of such patient; and, should the verdict be unfavourable, the parties accessory to such removal must abide the consequences thereof.

"And that any person signing a certificate of insanity (as a medical man) who is not authorised to do so under the Act of 8 & 9 Vic., is guilty of a *misdemeanour*, and will be proceeded against accordingly."

TO CORRESPONDENTS.

Dr. John Taylor, Huddersfield."—We have received Dr. Taylor's Essay on the Treatment of Pericarditis. Dr. T. shall have the proof and MS. by post, as soon as the former is struck off. The MS. is already in the hands of the printer. It gives us infinite satisfaction to have the power afforded us of laying before our readers a contribution to practical medicine of such rare sterling worth. One of our highest aspirations as a Journalist is to be permitted to aid medicine in advancing to her place as an inductive science.

A Correspondent" inquires our opinion of the portrait of John Hunter, lately published. We have not yet received it.

Our Hampstead Correspondent must stand over till next week, when we hope to obtain the information he requires.

Dr. Kidd's" communication from Paris has been received, and shall have early insertion.

"B. B." inquires the probability of the "Cyclopædia of Practical Surgery" ever being completed. We understand that Mr. Costello has made arrangements to complete the work. Part No. XII. is the last fasciculus published. We do not know when Part XIII. will appear.

Dr. C. W. Bell, of Manchester," lately read before the Devon and Exeter Pathological Society, an excellent paper "on the present Epidemic," which we hope to publish in an early Number. The extensive experience of Dr. C. W. Bell in the treatment of cholera, acquired while he held the appointment of Physician to the British Embassy at the Court of Persia, renders anything coming from him upon the subject worthy of the utmost consideration.

"X. Y. Z.," wishes to know what situations are in the gift of the Government for medical men. A guide to Government situations has been, we believe, lately published, and to this we must refer our correspondent.

"Our Correspondent at Brighton" will receive a private note. We fear the M.S. in question is mislaid.

"Dr. Sheridan Muspratt on the Blowpipe" will shortly be reviewed. If we simply *noticed* works we might press many into each number of our Journal; but as we really wish to *review*, and to inform our readers of the contents and value of a book, we cannot get on so fast as our correspondent seems to wish.

"Mr. Bulley's" case of urinary calculus removed by a solvent will be acceptable.

"Mr. Annan, of Kinross," on "Sympathy," shall receive our earliest attention.

"One of our Readers" is informed that we are in treaty upon the subject.

"Mr. M'Clure's" Paper—"The History of the Cholera and House Visitation, at Torpoint, Devon,"—has been received, and will be published as soon as our space will permit. Mr. M'Clure, who is a naval surgeon, was the first to volunteer for civil duties, when a want of medical men obliged the Plymouth authorities to apply to Captain Nicolas, the Superintendent of the Naval Hospital, for assistance at the first outbreak of cholera in that neighbourhood. He effectually carried out the system of house visitation, and his very interesting paper gives us the result of his labours, which have been acknowledged in grateful terms by the authorities.

"Mr. D. G. Carpenter" asks if a person vaccinated can have as a consequence of that vaccination more vaccine vesicles than he has had charged points inserted? Certainly not; he may have vesicles on other parts of the body, but they will not be identical in structure with those which result from the insertion of the lymph.

"Carvacrol."—The correspondent who asks for a formula for preparing Carvacrol is referred to the "Medical Times," for Jan 8, 1848, No. 432. We may briefly state, however, that it may be obtained by distilling the Ol. Carui with hydrated phosphoric acid, from which the Carvacrol separates itself in the form of an oil.

"Studens" inquires about the Polariscope, asking what it is, and where it can be procured. The Polariscope is a glass tube employed to determine the quantity of saccharine matter contained in urine or any other fluid, by causing a ray of linearly polarised light to traverse it by fixing to its extremity either a Nichol's prism, or a crystal of double refracting power, as a Tourmaline cut parallel to its axis. Dr Bushnan has described the instrument in the "Medical Times," for March 25, 1848, Dr. Golding Bird in his "Urinary Deposits," and M. Bouchardat in the "Repertoire Generale des Sciences Medicales," Vol. XVIII. The instrument, which we believe is only made in Paris, we have seen but once, and then in Germany. We will apply to our French Correspondent for further information on the subject.

"A Young Comparative Anatomist" asks, who first described the respiratory and motiferous nervous columns in insects? We believe Lyonet, upwards of eighty years ago

"A. B. C." proposes to send us a drawing of an acephalous fœtus We decline his polite offer with many thanks, acephalous fœtusses being abundantly well known.

The paper "On Life" is respectfully declined. Our correspondent is not the only writer who, in modern times, has represented heat as a part of the principle of life. The error consists in mistaking a necessary condition of life for life itself.

"Mr. Francis, of Faversham," complains of the irregularity in the publication of Mr. Wardrop's work on diseases of the heart. The work will be concluded with the present volume.

Thursday being a *dies non*, we were obliged to go earlier than usual to press, and thus many of our correspondents must remain unanswered until next week. Mr. R. G. Couch, of Penzance, Mr Cave Brown, of Tamworth, Dr. Tripe, Dr. Bulley, Mr. Leithead, Mr. Moyle, Mr. Mair, Mr. Walton, and many others, must accept our apologies, and the reason we have assigned for delay

ORIGINAL LECTURES.

HUNTERIAN LECTURES.

ON THE

GENERATION AND DEVELOPMENT OF THE INVERTEBRATED ANIMALS.

By RICHARD OWEN, F R S,
Hunterian Professor and Curator of Museum of Royal College of Surgeons, Corresponding Member of the Institute of France, &c

[Reported expressly for the "Medical Times," and revised by the Lecturer]

LECTURE XIII.

GENERATION OF INSECTA —General characters of the class and of its primary divisions and orders —All the species diœcious —Generative system of the Myriapoda —Vesicular testes and ladder like anastomoses of the two vasa deferentia in the Iulidæ advanced position of termination of sperm-ducts —Male organs of Centipedes —The single ovarium with single oviducts in Centipedes and the two oviducts in Iulus —Spermathecæ and colleteria —Development of embryo —Hexapod larva and their metamorphoses by multiplication of segments and joints —Affinities and place in the Articulate Series of the Myriapoda deduced from their development and metamorphoses

MR PRESIDENT AND GENTLEMEN,—The articulated animals with one pair of jointed antennæ and with jointed limbs, which respire air by stigmata and tracheæ, constitute the vast class of invertebrate animals, called "*Insecta*"

The common or typical number of articulated legs in this class is six disposed in three pairs developed exclusively from the thorax. In the Crustacea we saw that the number was greater, and that the limbs were developed from the abdominal as well as from the thoracic segments of the trunk Such is the case also with the Myriapodous insects; but these breathe the air directly by means of tracheæ, not by gills, and they have only one pair of antennæ they likewise manifest as we shall find, the typical hexapod character in their larval state,—a period during which, as in the Cirripeds, Epizoa, and Acalephæ the Myriapod shows more of its true nature and is more in accordance with the common type than during its final and oviparous stage

Taking, however, a survey of the tracheal air-breathing Articulata under their mature condition, they present more important characters in common, than any which indicate an affinity to the gill bearing classes, and we find them offering the same ground for a primary division as the Crustacea did, viz, in the number of the segments of the body

This number is constant and definite in the higher and typical members of the group, in which it is neither more nor less than *thirteen* in the rest it exceeds thirteen, and is variable

The thirteen jointed insects have one joint for the head, three for the thorax, and the rest for the abdomen, and, as the thoracic segments alone develope jointed limbs, this primary division or sub class of Insecta might be called *Hexapoda*

There is no distinction between thorax and abdomen in the indefinitely jointed division, and as all the segments save the first and last support jointed limbs, this sub-class is termed *Myriapoda* The Myriapoda I regard as a group equivalent to the Entomostraca, and, like them, they are the lowest organized, and the least numerous and varied of the two divisions of their primary group They are divided according to modifications of the mouth into *Chilognatha* and *Chilopoda*, answering to the genera *Iulus* and *Scolopendra* of Linnæus who first detected these natural divisions

The Hexapod insects may be classified.—

1st According to the phenomena of their development.

2nd. According to the structure of their mouths, or,

3rd. According to the nature of their wings

Agreeably with the first character, they would be divided into,—

Ametabola, or those that undergo no metamorphosis.

Hemimetabola, or those that undergo a partial metamorphosis; and

Metabola, or those that undergo a complete metamorphosis.

According to the modifications of the Trophi, instrumenta cibaria, or oral organs, the Hexapod insects are divisible, like the myriapods, into two groups, viz, the *Haustellata* or suckers, and the *Mandibulata*, or chewers and biters.

But this binary division is insufficient for the general propositions which the comparative anatomist has to enunciate, and I take, therefore, the third kind of characters, the value of which was first fully discerned by Linnæus, viz, that founded upon the organs of flight. Those Hexapod insects which are devoid of wings are called *Aptera*, those with two wings only, are the *Diptera* All the rest have four wings The *Lepidoptera* have four scaly wings, the *Hymenoptera* have four veined wings, crossing each other when at rest, the *Hemiptera* have one pair of wings partially thickened, and called hemelytra, the *Orthoptera* have one pair of wings wholly thickened, the other folded length wise; the *Coleoptera* have one pair wholly and much thickened called elytra, and the other pair folded cross-wise, the *Neuroptera* have four reticulated wings, the *Strepsiptera* have one pair of wings rudimental and curled up In the *Aphaniptera* both pairs are rudimental and functionless as wings Of these orders, the first five are "haustellate" the remaining four are "mandibulate" The Aptera are ametabolian, the Hemiptera and Orrhoptera are hemimetabolian, the remaining orders are "metabolian" These characters, therefore, briefly and succinctly express the highest generalizations, as yet reached, relative to the Hexapod Insecta

I have said, that the Hexapods have thirteenth segments, but, in the last stage of the metabolian orders one, two, or three segments may become blended together, and again, although we reckon the head as a single segment, the number of jointed appendages which it supports, under the name of antennæ, mandibulæ maxillæ, palpi, &c, indicates that here as in the Crustacea it consists essentially of several coalesced segments

With regard to the orders of the Myriapoda I may remark that the *Chilognatha* have two biarticulate mandibles, without palpi armed with imbricated teeth planted in a cavity at the upper extremity of the mandible, they have also a kind of lip situated immediately beneath and covering the mandibles, notched into four divisions, and answering to the two pairs of maxillæ of the Crustacea, whence the name from the Greek, signifying "feeding by jaws The Iulus or Gally worm is a type of this order The *Chilopoda* have the mouth composed of two mandibles with a small palp, a quadrifid lip, also the homologue of the crustaceous maxillæ confluent, two labial palpi hooked at the tip, and a second pair of jaws or foot jaws —the obvious homotypes of feet—terminated by a strong hook moveable and pierced beneath the extremity by a poison duct The Centipede (*Scolopendra*) is the type of this order of Myriapods, which "feed by feet"

All Insecta are diœcious In most the sexes are distinguished by external characters; these, however, are least conspicuous in the Myriapoda, but the external outlets of the generative organs of the male are, in the Chilognatha, as in many Crustacea, situated on a segment posterior to that which is perforated by the generative organs in the female.

In the male Gally-worm (*Iulus terrestris*), the testis consists of minute cœca appended, for the most part alternately, to the sides of a long efferent tube there are two of these on each side, which, commencing in the posterior fourth of the body, advance forwards, and unite on each side so as to form a pair of tubes; the cœcal glands continue to be developed, but in smaller number, each from one side principally of each of the common tubes. These tubes then approximate, communicate together by three or more transverse canals, and, after a slight bend or convolution, extend straight forward to the sternal arc of the seventh segment of the trunk, where they terminate by distinct orifices behind the seventh pair of legs.

The structure of the spermatic organ is so similar to that of the longitudinal tubes, that the secreting function is doubtless exercised by both parts; they consist of a thick mucous coat, with an external muscular tunic, they are situated beneath, or ventrad of, the alimentary canal, and between the two large salivary vessels. In the Crustacea the testes are dorsad of the alimentary canal, and their ducts external to the glandular appendages of that canal.

The transverse anastomosing canals, between the right and left testes, reminds one of the single transverse communication between the two testes in the lobster and in the crawfish, but this character is so multiplied—Mr. Newport having found more than twenty such transverse canals in one species of Iulus—that the testes offer no unapt resemblance to a ladder. In a large species the same laborious and eminent entomotomist discovered that the semicorneous intromittent organ was defended by an uncinated valve, serving as a holder or clasper.

The contents of the testes are a clear fluid at the hinder beginning of the organs, but it becomes thick and more opaque as the outlets are approached. The change is due to the appearance of numerous sperm cells, 1 450th of a line in diameter, with a highly refracting nucleus 1 750th of a line in diameter, lying close to the cell-wall. In the progress of development the nucleus enlarges and becomes conical, the apex protruding from the surface of the cell, which finally dissolves and leaves the nucleus free This is the spermatozoon its breadth always exceeds its height or length

In the *Iulus fabulosus* the cell-wall becomes enlarged at the part opposite to the nucleus, and produces there a similar nuclear body the whole thus appears like two of the spermatozoa of the *Iulus terrestris*, with their broad bases turned towards and touching each other

For these observations on the development and singular form of the spermatozoa of the Chilognatha, we are indebted chiefly to the labours of Siebold and Wagner

In the *Chilopoda* the generative organs terminate at the anal segment of the body, not, as in the Chilognatha, near the fore part of the body.

In the Scolopendra the male organs are more complex, and resemble those of insects The testes of the *Scolopendra morsitans* are seven in number, and closely packed in parallel lines, each testis is composed of two parts, fusiform and precisely similar to each other in mutual contact, but easily separable From each extremity of the fusiform testis arises a narrow duct, so that there are fourteen pairs of ducts arising from the fourteen secreting organs Each of the testicular bodies is hollow internally The ducts ultimately end in a common tube which soon becomes enlarged and tortuous, terminating by a simple aperture near the anus Just prior to its termination, the enlarged canal receives five accessory glands, four of which are intimately united, until unravelled, while the fifth is a simple cæcum of considerable length The sexual outlet is situate near the anus

There is very great diversity in the structure of the male organs in the different genera of Myriapoda

In the *Scutigera*, according to Leon Dufour, the testes are two fusiform organs with a duct continued from each extremity, those from the upper end anastomose together, and a long and slender canal is continued from the middle of the arch, which, after a certain course, becomes disposed in a series of progressively increasing transverse folds, and finally divides into two terminal slender pyriform sacs. These Leon Dufour regards as accessory vesicles The sperm ducts continued from the lower ends of the fusiform testes bend upward upon themselves, and dilate into reservoirs called "sper-

mathecæ," similar in size and shape to the testes themselves, and each of these terminate separately upon the anal segment.

The fusiform testes have many small pouches or diverticula produced from their outer side. In the genus *Lithobius* the testes are fusiform, but free at their upper pointed ends, and they are everywhere beset with numerous subspherical or graniform secerning follicles. Three long blind tubes—accessory glands—communicate with the proper sperm-ducts; the common opening being, as in other Chilopoda, at the terminal segment. Treviranus speaks of a small fleshy corneous penis in the Lithobius.

With regard to the female organs of the Myriapoda. In the *Iulus terrestris*, the ovarium is a simple elongated sac, with the exterior surface nodulated by sacculi; the larger ones, of uniform size, being arranged in a double series. The ova are developed and completed in these sacculi, one in each; the germinal vesicle here is surrounded by the yolk and vitelline membrane; upon this is laid the thin layer of albumen and the corion before it passes into the common oviduct. The ova in the earlier phase of development form small projections at the interspaces of the larger and more regularly-sized ovisacs containing the more mature ova. The common elongated sac extends from the anal segment forward to near the fourth segment, where it divides, and the two vulvæ are situated on that segment behind the second pair of legs. The ovarian tube is situated beneath the alimentary canal; not above it, as in the Crustacea. If the male apertures on the seventh segment indicate, by the analogy of the Crustacea, the hinder boundaries of the thorax, we see that the more advanced position of the female apertures keeps up that analogy. Another interesting analogy presents itself in the double aperture of the generative outlets and the double intromittent or clasping organs in the male *Iulidæ*. I allude to the serpent tribe, which these Articulata resemble in their length, and slenderness, and tortuous movements; for the serpents alone, amongst vertebrata, present the double termination of the generative ducts and the double unciform claspers.

In the *Lithobius forficatus*, the ovarium, a single elongated blind sac, extends from the anal segment to near the middle of the body, and is supported by the tracheal capillaries. It is beset by numerous subpedunculate unilocular bursæ, each containing a white globular ovum. These give a granular aspect to the exterior of the ovarian tube: which tube, Léon Dufour suspects to be naturally divided by a median longitudinal septum.

On each side of the termination of the ovarian tube is a racemose colleterium, consisting each of two rows of granular utricules: a common duct and reservoir communicates with the oviduct.

On the interesting subject of the development of the Myriapoda, some important facts were early recorded relative to the metamorphoses of the Iulidæ by Degeer and Savi; and their generation has been very ably and minutely worked out by Mr. Newport, whose valuable memoir on the subject has been published in the Philosophical Transactions for the year 1841.

The *Iulus terrestris* hibernates from October to March; the female is probably impregnated prior to hybernation, for her first act, after awakening from the long winter-sleep, is to prepare to disembarrass herself of the load of impregnated ova; the act of oviposition is generally over by the month of May. She previously excavates a special nidamental cavity in the soil, and is careful to place the eggs where no access of light, and only a certain degree of moisture, can affect them. In this process she bores the soil about an inch in depth, just wide enough to admit her own body, and then excavates a circular cavity by removing the soil, pellet by pellet, the earth being made up into a little pill by mixture with her saliva; she withdraws herself backwards from her hole, bringing up the pellet, which is held between her bent-down head and the first pair of legs: it is then passed backwards to the second pair, which transfers it to the next in succession, and so onwards, until it is removed quite out of the way. When, by the repetition of this manœuvre, the egg-chamber is completed, oviposition takes place, and the entry to the chamber is carefully closed by earth thoroughly moistened, so as to form a thick paste, which she gently presses into the entrance, and fills up nearly to a level with the surface of the soil. Thus protecting the eggs from enemies that would devour them, or from the atmosphere and light which might decompose them. In this operation we may perceive that the large salivary glands have a function analogous to that of the silk glands of the *Bombyx mori*.

In the fresh-laid egg the chorion is transparent, but it soon becomes opaque, soon dries and shrivels when exposed to the air. The first period of development occupies about twenty-five days, when the chorion is ruptured, the egg previously augmenting in size and becoming reniform. The embryo may be recognised about the twelfth day, but presents no trace of segments or limbs; it is bent upon itself. On the thirteenth or fourteenth day there is an indication of segments on the ventral aspect. On the eighteenth day the shell bursts along the dorsal surface, and on the twenty-fifth day the embryo protrudes, by the elastic quality of its body overcoming the compression to which its growth has subjected it; but the embryo is passive and motionless, and is still connected by a reflection of an amniotic covering upon the inner surface of the membrana vitelli, which connexion Mr. Newport calls the umbilicus." There is now a head and seven segments, and the antennæ may be seen budding from the sides of the head. The internal structure of the embryo is wholly cellular, with a cavity resulting from the coalescence and liquefaction of certain central cells. On the third day after exclusion the embryo is passive, motionless, and still attached to the shell by the funis-like duplicature of the amniotic covering, and it is protected by the two halves of the egg-shell, suggestive of an analogy to the entomostracous *Cypris*. The head, antennæ, and segments of the body are better marked; but the embryo is still apodal, though rudiments, or buds of thoracic limbs, now begin to be discernible. Some of the peripheral cells become pushed into these buds of limbs, making them obtuse prior to elongation. On the ninth day the funis is ruptured, and the alimentary canal completed; but other internal parts consist of cells of different sizes. On the tenth day the dorsal vessel betrays itself by its pulsations; it drives the colourless blood to the head, which now becomes corneous; the antennæ become clubbed, and now a simple ocellus may be distinctly seen on each side. On the seventeenth day the embryo leaves the debris of its shell: it presents definite segments, articulated antennæ, and three pairs of jointed legs; it is, in short, a hexapod larva. But by the next stage of progress it quits the high road of insect development to enter a bye-path of its own. New segments are formed from the penultimate or germinal segment; a remnant of the funis is converted into a rudimental anal spine. The amniotic covering and the rest of the funis are moulted.

The first spontaneous movements of the embryo are to burst and slip off the amnion, with the first integument, after which exertion the larva reposes, with slight occasional movements of the antennæ. We may now distinguish a prothorax, with eight other primary segments; six new segments have also been formed at the germinal space, but these are short, and collectively are only equal to one of the original segments. The new segments are not formed by a division of the old, but by gemmation from the penultimate segment at the germinal space. The primary three pairs of legs are developed from the second, third, and fifth primary segments. New pairs of limbs bud out from the sixth and seventh segments. The female apertures are perforated in the fourth segment; the male outlet is established at the seventh segment, when this is near the posterior end of the body of the larva.

The antennæ first begin to move, then the legs, and the first instinct of the locomotive larva is to shun the light. In this progression the anal segment is first expanded, and attaches itself to the firm surface; then the body is carried forwards, the motion being propagated from segment to segment. In the progress of growth these are successively added at the germinal space; the new segments being always produced beneath the common integument, which is afterwards moulted. These segments are added in a certain numerical ratio, six at a time, between the antepenultimate and the penultimate segments. Movements of the larva are always observed to be fettered by the approach of the ecdysis. All the limbs superadded to the primary three pairs are bifid; and these double legs are analogous to the prolegs of caterpillars. The further course of growth is attended with a more distinct definition of the segments; and by transverse indents of the primary segments. The limbs also become more straightened. The whole period of development occupies four or five weeks, and then development is superseded by the mere act of growth.

With regard to the Centipedes, we still need a series of researches to make us properly acquainted with their development. A French naturalist has recorded a series of researches on the genus Lithobius. This is a modified centipede, consisting of seventeen segments, and having fifteen pairs of extremities. In the month of May, the larva presents but ten joints and seven pairs of legs with two simple ocelli on each side of the head. Early in June, it had acquired twelve segments, and eight pairs of legs, and the head presented three ocelli on each side. Later on in the same month, the segments had increased to fifteen, and the legs to fifteen pairs, and the number of ocelli was eight; finally, two more segments were added, and the cluster of ocelli included twenty on each side. The chief distinction between the Lithobius and Iulus appears to be, that the successive joints are not developed, as in the Iulidæ, at the posterior part of the body, from one particular germinal space, but at the interspaces of the pre-existing segments.

With regard to the affinities of the Myriapoda as they are illustrated by the known phenomena of their development, we discover in the peculiarly localised power of superadding the additional joints in the Iulidæ, a marked analogy to the annellides; yet the appendages of the segments being distinctly jointed limbs, we have in these a well-marked character of the superiority of the Chilognatha. Then, in reference to the Crustacea, which the Myriapoda more resemble in their jointed antennæ and limbs, we perceive also an interesting additional analogy in the Chilognatha, in the circumstance of the organs of the generative apparatus not terminating in the homologous segments in the male and in the female; whilst in both they are situated nearer the anterior part of the body. But this crustaceous character disappears in the Chilopoda. And when we perceive that the first form of the articulated animal with jointed limbs, which the Myriapoda assume, is that of the hexapod insect, and further, that in departing from this type, the pair of limbs successively added in the Iulus are like those temporary ones in the caterpillars, of a different character from the primary six,—we cannot but derive from these facts a well-founded [illegible] in the importance of that character of the [illegible] system which led us, at the beginning, to [illegible] the Myriapoda with the Insecta rather than the Crustacea.

ORIGINAL CONTRIBUTIONS.

CONTINENTAL MEDICINE.

By Dr. KIDD.

Microscopical discoveries crowd on us from every quarter since Mr. Brittan's announcement. In fact, every one with a little time at his disposal, and so fortunate as to possess a microscope of tolerably respectable powers, has been seeing what one should, *à priori*, expect he would see, sundry of these cellular bodies, more or less developed, the offspring very possibly of merely accidental causes, and in no very prominent way connected with cholera.

Dr. Baly tells us he saw similar bodies—distinct parasitic fungi—so far back as 1844, at a time that dysentery prevailed very severely in Milbank Peni-

tentiary, and from his account it would appear, that those seen in cholera differ very little, except in being smaller in size, more flattened, and not so compound structurally as those observed in dysentery. He seems, I believe, to think the latter of extraneous origin, which may be doubtful; for, though bearing many resemblances to the Protococcus genus, they have not the usually well-defined outline of vegetable structures, and are more likely to be of a character more indigenous to the system itself.

Mr. Williams, of Swansea, as early as the 10th of July, of the present year, in the rice-water evacuations of cholera, discovered similar bodies, but made little of the matter—singular polygonal confervoid bodies; in the more advanced stages of the disease, these granulations constituting literally the entire of the solid matters of the discharge, and forming when dried an impalpable powder of very peculiar lightness.

On the Continent the thing is as old as the hills. At Berlin, when I was there, Boehm, who succeeded Dieffenbach, and others were examining the rice-water discharges with the microscope. Respecting the mucous membrane itself, the chief alteration observed, was an almost universal throwing off of epithelium cells, more especially about the lower part of the ilium, the stomach being less affected. In the rice-water evacuations, Boehm has seen all kinds of epithelium cells, and other cellular formations; but never dreamt—and your true Berlin man is a great dreamer)—of ascribing all the phenomena of cholera to such things. He found, too, a *fungoid production*, the same, I take it, at least nearly allied to the one now observed, but very properly looked on it as purely accidental. In France again, Donne noticed the existence of some microscopic products as early as April of the present year, and later still, A. Becquerel has examined the rice-water discharges under every possible shade of the disease. Andral first, perhaps, in France, noticed the presence of albumen in the filtered liquid, a point still further corroborated by Mialhe, and all have seen these cellular formations, and made nothing of them.

Becquerel arrived at some rather singular results. The matter held in solution in the rice-water vomited matter held a constant relation to the cellular matter held in mere admixture; the more of one, the more also of the other. In all his cases, the longer standing the disease the more of each. The vomited matter was generally *acid*; the proportion of chloride of sodium unusually great; but in every other way resembled, in its composition, ordinary serum of the blood. The fæcal evacuations, on the other hand, were alkaline, owing to ammoniacal salts, but differed in little else from the vomited matter. The serum of the blood itself was remarkably dense, abounding in fatty matters, due perhaps to absorption.

It was Mr. Shandy, the elder, I think, that prided himself in accounting for nothing like any body else, and at the present moment it appears something of a virtue to be able to do the same. The ancients, good easy people, put down everything very wonderful to Hercules; he it was that separated Ossa from Olympus and opened up the vale of Tempe. We, on the other hand, go into the opposite extreme; and the origin of a wide and wasting plague, like that now fading happily from among us, is sought to be explained by a set of invisible cells, that have as much to do with it perhaps as the aforesaid Hercules. That cholera, and fever, and some other diseases, have a peculiar elective affinity for decomposing matters abounding in fungi every one is aware, nay, that the presence of these fungi, in common with other bodies, and their transit, from place to place, saturated with certain specific principles, account, in a most wonderful way, for many of the apparently contradictory phenomena of the contagiousness or non-contagiousness of these diseases cannot be denied. These questions however, should be kept distinct and separate (in close reasoning on the subject) from the particular epidemic influence itself at work, and capable of being thus attracted. It would be a very meagre way of putting the matter, to say the north pole of a magnet was the south, because they are generally found together, or that a boarding-school and scarlet fever were one and the same, because of an old and traditional connexion existing in that direction also. We should be on our guard against jumping at once to conclusions. The microscope has more than once given to the world theories of doubtful paternity; the wish has been too often father to the thought, and thus retarded the interest of true science. If cholera have an affinity for decomposing matters, and every one that has studied the disease must say it has, this is clearly a different thing from considering the two, one and the same.

Dr. Cowdell, of Dorset, is another who has already "pronounced" on the subject. He, too, has seen cellular bodies—it would be, perhaps, a mystery and a wonder if he did not, in the complex organic mixture, the rice-water discharge. Nay, more, in the clammy sweat accompanying collapse, he has seen the same thing, the disjecta membra in each instance differing very little.

Mr. Brittan's account of the matter is plain enough, and, fully borne out as he is by Mr. Quekett, as to the fungoid character of what he has described, we may perhaps rest satisfied with the fact. Any one, however, who has had two minutes talk with the great histologist of Berlin, will not in any way wonder at such revelations. Myriads of these "shadows" of organic life perpetually floating about us everywhere, thick swarms settling ever and anon on the vegetable and animal worlds; nay, whole worlds of rocks made up of nothing else. Ehrenberg's all-animating microscope has, indeed, revealed to us matters in this way little short of the fabulous. A single inch of a particular German slate he has shown to consist of not less than forty thousand millions—a perfect firmament of minikin shells! In the depths of our present seas, as well as the tops of the highest mountains, uncounted myriads of analogous creatures existing in every point of space. Every visitor to Berlin must have seen these things till he has ceased to wonder. Th Protococcus, too, this particular genus about which, at present, such a noise is made, existing among even the snows of the polar regions, carried thither by evaporation, as well as in the depths of the ocean itself: like another Ariel,

"In the ooze of the salt deep
As well as upon the sharp wind of the north:"

Everywhere, in point of fact, that the microscope has looked for them. It is not to be wondered at, then, if we find them in our streams and rivers; in the atmosphere along their banks; in the water given to cholera patients, which they crave in such quantities; in ice; in the almost unchanged rice water discharges.

Among the crowd of things discovered in the rice water evacuations, I think we are entitled indeed to ask, Are not the cellular bodies under discussion purely accidental. Swayne tells us, in addition to them he has found a large number of crystals, triple phosphate and urate of ammonia, lithic acid itself, and oxalates. Lanza, of Naples, found almost invariably worms; Mr. Herapath, carbonate of ammonia, &c. Nay, Mr. Brittan himself says, that he has found them in different degrees of development, as though, I take it, they were passing harmlessly through the system; and, in the most rapidly fatal cases, where they have been perhaps destroyed, or the patient has had no water, he has not discovered them at all. In water condensed from the atmosphere of a sick ward, as in the polar snows already alluded to, they have been also found. That quantities of such bodies have been floating in the air there can be little doubt. The curious shower of black matter in Ireland, mentioned by my friend Dr. Barker, some of which he transmitted to Ehrenberg, was, I believe, of that character; and a more recent shower of distinct confervoid bodies in that country leave little doubt on the point.

The breaking out of cholera, generally, in low damp situations, connected for the most part with rivers; the facility with which it travels up and down their banks; the evaporation always going on in such situations, must make it ever a complex but not uninteresting question, What part the fungoid bodies under consideration play in the genesis of this frightful malady. A curious question would be, whether there is really any proportion between the amount of evaporation and the prolonged character of cholera, in any given locality. The mean annual amount of rain here in Paris, for instance, is, I believe, about 20 inches; in London, something about 25; in Geneva, 30; while, on the coast of India, it averages as high as 120; at Cuba, 140. That certain electric phenomena attend such changes should also not be forgotten. We must accumulate facts, not build up theories.

Sir James Murray says he has found magnets lose almost their entire power in the vicinity of grave-yards; and electric machines to be almost incapable of effecting the usual experiments. An old friend, Quetelet, of Brussels, has noticed a change in the electric relations of the atmosphere in Belgium during the late epidemic. The extraordinary experiments of Matteucci and of Heale, on the electrical currents traversing the circulation; some ingenious opinions which I have heard from Dr. Stevens, (who has done more, perhaps, for cholera than any man in Europe,) leave on my mind little doubt, that a disturbance of electricity is very intimately mixed up with the origin of cholera; and that in examining cells and fungoid productions like those of Brittain and Swayne, we are looking at *posterior* results in the chain of causation, if they are even that. All the phenomena of cholera, to my mind, are easily explicable by an interference or stoppage of the electrolysis going on in the system radiating from the cœliac axis,—isolated, according to the recent views of Heale, by the peritoneum. It is, of course, another thing whether this takes place, —we have neither proved it nor the contrary.

The study of terrestrial magnetism is, of all others, that carried on with most assiduity, at present, on the Continent and at home, with results, need I say, of the most wonderful kind. These results have been arrived at by multiplied observations. In animal and pathological electricity, on the other hand, we want observations; we want facts on which to build up our principles; we require the tabulated results of a set of observers without theories to uphold, before we get at anything like the isodynamic lines, the lemniscate and other singular peculiarities of magnetic force of our more industrious physical friends. The relations of electricity and light have lately startled the scientific world; those of electricity and disease are not less evident,—but still a chaos.

The singular experiments of Reichenbach, in Germany, among others, display the excessive sensitiveness of some persons to electrical currents. In many instances, in particular conditions, the placing a patient in bed east and west has produced the most remarkable phenomena,—as suddenly removed by changing the patients into the magnetic meridian. Some of his patients, again, he made so susceptible, that, in Church, looking towards the altar west and east, they became quite sick; recovering as quickly by changing to the transept north and south.

The tendency of cholera to the west belongs, perhaps, to this class of phenomena; more correctly, its trajet has been the diagonal of two forces,—the rotation of the earth from west to east in one direction, the magnetic poles the other. It is quite singular, indeed, the accuracy with which it has observed this course.

In the former visitation, Dr. Prout discovered a very perceptible change in the weight of the atmosphere all the time cholera was in London. Reid Clanny, Muller, of Petersburgh, and Adair Crawford observed similar phenomena, quite remarkable: the last mentioned, I think, that magnets lost their power, and the machine its action: to which we may add the apposite fact lately noticed by my excellent friend, Sir Alexander Downie,—the absence of cholera in the vicinity of the springs along the Rhine that give out carbonic acid gas. A few more facts of this kind, indeed, and some more magnetic observations, and some one to string them together, will do more for the history of our half naturalised plague than peering into the *adyta* of cucumbers for sunbeams.

Paris, Nov., 1849.

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

DISEASED BREAST—HARE-LIP—HEY'S OPERATION—EXTRACTION OF URETHRAL CALCULUS.

Mr. Fergusson had several operations on Saturday last of an interesting character.

The first case brought into the theatre was a diseased breast. There were old sinuses running in various directions, which had existed for a long time, and which were of such a nature as to lead to the suspicion of carious bone. Mr. Fergusson ha carefully examined the case before in the wards, but could not detect any dead bone. As the sinuses however, did not evince any disposition to close and were in a callous condition, Mr. Fergusson determined to lay them freely open, which proceeding, besides facilitating the healing of the parts, allowed a free examination of the subjacent ribs. No carious bone was found, but in one or two places th periosteum was gone. During this exploration vessel bled copiously, but it was readily checked by pressing some lint firmly upon the spot from which the vessel sprung.

The next patient was a young infant, with a very bad hare-lip, accompanied with a protrusion of a portion of the alveolar process. The projecting part was removed by the cutting pliars, and the usual incisions for paring the edges were made, and the parts brought accurately together by the needles and twisted suture.

The next case was one of extreme interest, both on account of the history of the patient, and of the operation which was performed upon him. The patient was a French officer of Artillery, who had fought with the Hungarians during the late disastrous war of independence. It appears that, during the campaign, a portion of one of the feet had been carried away by a gun-shot, and, more over, mortification of both feet had taken place, and by these means the poor fellow had lost all hi toes. On the right side the parts had healed kindly, and there was a very good stump; but on the left foot union had not taken place, and nearly the entire metatarsal bone of the great toe was exposed and necrosed, and the soft parts around were in a morbid condition. In order to remedy this state of things, and for the purpose of forming an useful stump, Mr. Fergusson determined to put in force the operation of Hey, namely, removing the entire metatarsal bones from their articulation with the cuneiform and scaphoid bones. The operation was performed in the following manner:—A curved incision was made in front, over the apex of the stump, and the soft parts were dissected back; a similar incision and dissection was made behind; the articulations were then cut into in front, and the whole of the metatarsal bones removed. This proceeding was one of considerable difficulty, in consequence of the operator having no purchase for his left hand; but it was completed in a most able and effectual manner, and plenty of soft parts were left to cover the ends of the bones. After the operation Mr. Fergusson stated that he would not have removed so much of the bones, had there been sufficient integument to cover them; but, under the circumstances, he was obliged to remove the entire metatarsus.

The next and last case was also one of great interest. The subject of it had been under Mr. Fergusson's care some three or four years since in King's College Hospital for symptoms of stone in the bladder, and at that time he had operated upon him, and had removed a mass of calculi from the neck of the bladder; the patient recovered, and went out of the hospital; but Mr. Fergusson had occasionally, when passing a catheter for a stricture the patient subsequently laboured under, fancied that he could detect a portion of stone near the neck of the bladder. About a month ago, the patient was suddenly seized with an attack of extravasation of urine, for which he was again admitted into the Hospital, and from which he very nearly lost his life; but, under proper treatment, the application of free incisions, and the continued use of the catheter, the patient made a most excellent recovery; but a fragment of stone was discovered in th urethra, near the bulb, and as it was impossible to extract it in any other manner, Mr. Fergusson d termined to cut down to the urethra, through th perinæum, and extract it.

The patient being placed under the influence o chloroform, and in the position for lithotomy, short staff was introduced, until its point met wit the stone. An incision, about an inch in length, wa then made through the centre of the perinæum, upo it. A small scoop was then introduced through th wound, but the operator was unable to remove th calculus. A small pair of forceps were subsequentl introduced, but with a like result. Mr. Fergusso then carefully introduced his finger and thumb, and by this means, extracted a calculus exactly the siz and shape of a common clove, which sufficientl accounted for its eluding the grasp of the forceps The urethra and bladder were then carefully examine and no more calculi were found.

LONDON HOSPITAL.

Reported by Mr. ALONZO H. STOCKER.

GONORRHŒAL OPHTHALMIA.

Case 1.—John Rice, aged 23, shipwr ght, an of somewhat debilitated appearance, was admitted an in-patient under Mr. Curling, October 18, 1849 suffering from gonorrhœal ophthalmia.

On admission, the patient's eyelids were swollen and inflamed, so that he could not voluntarily sepa rate them, whilst from between there exuded a thick purulent discharge. The eyes have been closed fo three days.

On separating the lids the conjunctiva was found exceedingly inflamed, and the surface covered wit a prominent granular mass, in which the cornea wa imbedded

The interior of the eyelids were in a similar gran ular condition, whilst from the whole surface a thick muco-purulent fluid was secreted.

The eye generally is vascular, and there is grea intolerance of light; the iris is natural, and th pupils act properly.

Around the margin of the cornea, at its uppe part, superficial ulcerations were perceptible, and from these small vessels were observed radiating towards the centre.

Little or no pain was complained of, except upon he admission of light. Both eyes were similarly affected.

History.—The patient is single, and contracted gonorrhœa two months since, for which he sought advice at St. Bartholomew's Hospital, and obtained an injection. This he continued to use for about a month, when he was almost cured, a very slight discharge only remaining. At this time, having obtained some work, he ceased attending, and ne glected himself, the consequence of which was, that about a week afterwards the discharge re-appeared. He returned to the use of the injection, by which e again became relieved.

Ten days before his admission, his eyes became sore, the conjunctiva reddened, and accompanied with pricking and darting pains, and an increased ow of tears. He applied to a surgeon, of whom e obtained a collyrium; but, finding himself getting worse, he came to the Hospital, when he presented the condition above described.

Two or three days after the eyes became affected, the urethral discharge ceased, and has remained so ever since.

He was ordered full diet, and milk; ang. nit., v. gr.; aq. dest., ℥i., ter die utendum.

Oct. 19.—There is little or no constitutional disturbance. The eyes are much the same; if anything they are better.

21st.—Much better. The granular appearance has all but disappeared, one or two small spots being the only traces left. The conjunctiva is, however, extremely vascular. The purulent character of the discharge is replaced by a serous one. The swelling of the lids has entirely subsided, and there is greater tolerance of light, the patient being enabled to open the eyes to the full extent.

The ulcers on the cornea are almost gone, a mere speck indicating their existence.

To-day the patient complained, for the first time, of his right ankle, which, on examination, was found swollen and painful. He has had no sprain to account for it; but it has been gradually coming on for two or three days.

Hirud. vj. to be applied to it. Rep. guttæ.

23rd.—The patient still continues to improve; the vascularity is disappearing, and also the quantity of tears, whilst the man's sight is improving, being able to bear the diffused daylight without much pain.

25th.—The ankle being still very painful, hirud. vi. were applied, to be followed by warm flannels. Rep. guttæ oculi.

Nov. 7.—Since the 28th the patient has continued to improve; the ankle is much better, a little weakness only remaining. The eyes have now almost regained their natural appearance, but little vascularity remaining; whilst the patient can bear the ordinary light without any inconvenience. Small nebulæ alone remain, indicating the previous ulceration on the cornea.

On the 3rd the discharge from the urethra re-appeared. For this he was ordered P. cubibæ ʒj. ter die.; under which treatment the discharge has now almost ceased.

Nov. 13th.—Discharged, made an out-patient; the discharge from urethra having all but ceased, and the eyes restored to their normal condition, there being only a little weakness of them remaining.

Mr. Curling applied in his last three visits the stick of nitrate of silver to the still slightly granular condition of the lids.

INFLAMED BURSA.—ERYSIPELAS.

Case 2.—Thomas Blaisley, aged 36, labourer, applied as an out-patient to Mr. Critchett, Nov. 3rd, 1849. He states, that whilst coming out of a stable-door with a weight in his hand, he slipped, and fell upon his knees, on some small stone-paving, by which a small wound was produced, which penetrated the bursa, over the patella of the left knee.

The accident caused considerable pain; but, from the small and apparently trivial nature of the wound, the man followed his usual work,—a small piece of sticking-plaster alone being applied to the sore.

The next day the part became excessively tender, he pain being aggravated on walking, or otherwise moving the joint, whilst the parts around became swollen, and from the sore a thin purulent discharge as secreted.

This continued to increase until he applied here five days after the accident, when the knee was found considerably swollen and inflamed; inflammation of the bursa had been set up, which had proceeded on to suppuration—the matter oozing from the sore when a little pressure was made. For four or five inches, both above and below the knee, a high degree of erysipelatous inflammation extended, the joint being very tender and painful, especially at night, or on moving the limb.

He was ordered lot. argent. nitr. ℈j. ad ℥j. aq. dest., to be freely painted over the whole of the inflamed surface, night and morning, and to poultice he sore.

As the man was in other respects in a good state of health, no medicine was ordered.

Nov. 7th.—The man to-day is able to walk and bear pressure, without its giving any pain. The erysipelas has entirely disappeared, and there is little or no swelling or pain. The surface is blackened from the action of the nitrate of silver, and is beginning to desquamate, and the skin has a loose shrivelled appearance.

The swelling over the patella is much diminished, and the wound discharges freely. Rep. lot.

14th.—As the patient lives at some distance, and the knee has been very much better, the man has not applied since the 7th.

The knee is now quite well; the bursa does not discharge at all, and the superficial wound has healed; the cavity of the bursa having become apparently obliterated.

A small piece of plaster was applied, and the man discharged cured. This case is interesting as showing a well-marked instance of acute erysipe-

latous inflammation following a wound into a bursal cavity, a very frequent result of these accidents; but it is especially worthy of notice as affording a remarkable example of the rapidity with which a strong solution of the nitrate of silver subdues the most acute forms of erysipelatous inflammation, when local in its origin, and unaccompanied by constitutional disturbance.

It may be observed, that only three days sufficed to remove every symptom, and I think experience will bear me out in the assertion, that no other plan of treatment would so rapidly or effectually have removed this affection.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

CHOLERA IN AFRICA.

The accounts from Africa continue to bring a deplorable description of the ravages which the cholera exercises in that country. The following is an extract from one of the letters forwarded by the last packet:—

"Oran, November 5.

"Consternation reigns at Oran. It is said that 700 of the military, and 3700 civilians have been already cut off, without including the Jews, Moors, and the deaths reported at the mosques. One-sixth, at least, of the population has been removed. All the shops are closed, and business is entirely suspended. We have nothing but firing of cannons and lighting of fires to purify the air. Thirty criminals are employed in digging the trenches for the dead, who are collected every evening in long wagons. One batallion of light troops, 400 strong, has lost 200 men; the 2nd Chasseurs has lost 80. M. Poulain, chief Surgeon of the Military Hospital is dead; his successor, M. Hennequin, is dead likewise, and the same fate has just struck the head Physician of the same hospital, M. Goedrop. The four Sisters of Charity attached to the establishment have also been cut off, and an infinite number of hospital attendants."

In many other localities, the epidemic prevails with nearly equal intensity; but it appears to have attained its maximum; at least, it is rapidly marching on the desert, where the plague of war already decimates both natives and invaders.

PUBLIC HEALTH IN FRANCE.

From so melancholy a picture, it is pleasing to turn our eyes towards home, where peace and science are beginning to distribute their benefits. The great chemist, Dumas, is, as you know, our Minister of Commerce and Public Works. The advantage of having a truly scientific man connected with the Government of the country has already become apparent. The new Minister has appointed a Committee of practical and competent men to organize a general system of public baths and washhouses for the poor. These useful Institutions exist in great numbers here, but they are private speculations. M. Dumas desires that every parish shall have an establishment of its own, accessible to the poorest members of the community; they, in fact, are most in need of them.

Another question taken up by M. Dumas is that connected with the Medical Service of the Spas in France. The mineral waters of France are numerous and of almost every variety; but, if we except the sulphurous springs of Barreges, and the alkaline waters of Vichy, are comparatively unknown and neglected. M. Dumas desires to turn public attention to these natural sources of health, and, with this object, is about to create a Medical Clinique connected with them, and intended to illustrate their properties. It is also reported, that the Minister of Public Works strongly recommends the closing of the Hôtel Dieu, and the transfer of the patients therein contained to the new Hospital of the Republic in Clos St. Lazare. It is very probable that this improvement will be adopted, for nothing can be more insalubrious than the site of the Hôtel Dieu, the excessive mortality dependent on which has long been a source of regret and useless complaint to the medical men of the establishment.

SUCCESSOR TO BLANDIN.

The concours for the chair of Operative Surgery, vacant by the death of Blandin, commenced on Thursday last. There are no less than ten candidates, amongst whom may be distinguished Malgaigne, Robert, Maisonneuve, and Nelaton. The concours will be prolonged for a month, at least: and whatever be the result, will, at all events, supply a most competent Professor. In England it is thought enough to be the nephew of a great surgeon, or the son of a small one, to entitle the most moderate capacities to the highest places. Here, as of old, people say, "*stemmata quid faciunt;*" and when a young surgeon asks for a Professorship, or aspires to an hospital he must give public proof of capacity before a select court and an enlightened audience. If the best man be not always selected, a bad one never is, and this argument alone is enough to decide the question in its favour; yet, strange to say, many of those who defended this admirable Institution most warmly when they were young, are now either cold supporters or open enemies. But men change in so many ways.

GUTTA PERCHA CATHETERS.

M. Civiale has recently employed, with much advantage, one of the new catheters in gutta percha which I mentioned in a former letter. Having extracted a very large calculus by the hypogastric operation, M. Civiale placed a gutta percha catheter in the urethra and left it there for nineteen days. M. Civiale remarks, that the new catheter adapts itself much more perfectly than the old ones to the curvatures of the urethra; it likewise produces little or no irritation; and, when removed from the bladder, on the fourth and seventeenth days, it was found perfectly smooth both externally and internally; perfectly free from deposit; in fact, one would have thought that it had never been used.

NEW MEDICAL SOCIETY.

A new Society, called "The Hospitals' Medical Society," has been recently established here, and its discussions promise to furnish much interesting matter. At one of the last meetings senile *ramollissement* of the brain was on the tapis. M. Bouchut showed other causes than those indicated by Broussais, Rostan, and Abercrombie. In nearly all the cases examined by M. Bouchut were found "incrustation of the parietes of the cerebral vessels, accompanied by fibrinous coagula." In some cases the clots are so considerable as to reduce the arterial calibre by two-thirds. Hence, the natural effects—softening, or even gangrenous state of the cerebral pulp, from want of due nutrition. Besides, it is a well known fact, that ligature of the primary carotid often gives rise to cerebral gangrene from the same cause.

TRANSFORMATION OF MATTER—HABITS OF THE SILK-WORM.

Within the last few years some men of original minds have given a new direction to their studies, which promise already to produce results of the most interesting and important kind. Disregarding the sarcasms of the ignorant and prejudiced, they have attempted to unveil the secrets of nature in her most mysterious operations, and to show that many of the phenomena of life, hitherto accepted as inscrutable, may be explained by those simple and well-known laws which govern universal matter. Amongst the different subjects connected with this new branch of science, one of the most interesting perhaps is the link which unites into one vast whole the various classes of bodies that constitute animate and inanimate nature, and in no other branch of knowledge have more important discoveries been made than those which reveal to us the graduated connexity of parts apparently most dissimilar, or the transformation of forms and substances into other forms and other substances which have hitherto been regarded as essentially distinct from and incompatible with them.

Thus, for example, the essences of animal and vegetable life have ever been considered as totally dissimilar and inconvertible; yet some modern discoveries would lead us to presume, not only that they may be mixed together in the same substance, but that the eye of the natural philosopher can follow the transformation of the one matter into the other. M. Decaisne had long since directed attention to certain animated globules, which he denominated zoospores, and which are detached from some of the fungi. The Endochromes of certain vegetables are endowed with spontaneous motion. Finally, the history of those curious bodies, which, according to M. Montagne, enjoy successively animal or vegetable life, according to the period of their existence, prepares us for the fact now announced by M. Guerin, that he has witnessed the transformation of animal into vegetable matter in the body of the silkworm. According to M. Guerin, certain corpuscles, which form the nucleus of the blood-globules of the silkworm, are transformed into the roots of a fungoid body, whose subsequent vegetation constitutes the disease known under the name of "muscardine."

When examined under the microscope, the blood of the worm is found to be composed of a transparent albuminous fluid, containing myriads of nearly spherical bodies. The largest of these do not exceed the 1-100th of a millimetre in diameter. These globules appeared to be endowed with individual existence; they are constantly reproduced during the life of the insect, and undergo the following changes:—

1. The newly-formed globules are smaller, and present in their centre a single point of less transparency.

2. The globule has now increased in size. The centre contains a nucleus composed of several granules perfectly equal, and appearing to give to the nucleus a movement of systole and diastole.

3. At a still later period the granules separate from the nucleus, and advance towards the circumference.

4. Finally, the granules appear to endeavour to burst the envelope of the globule, which they push before them, forming little buds. At length, they do penetrate the envelope, and at once form other globules similar to the parent one, clothing themselves with a new and transparent membrane, which appears to be formed by the surrounding albumen.

Such is the condition of the blood in the healthy state; but when the insect becomes infected with the "muscardine," either naturally or by inoculation, another series of phenomena presents itself. Long before the death of the insect, we find a great number of blood granules mixed up with small navicular bodies, which subsequently become the thalli or roots of the botrytis muscardinensis. It is at this period of the malady, that the transformation of animated blood-corpuscles into vegetable matter was discovered by M. Guerin, who thus expresses himself:—

"In the blood of the worm (No. 3) which had been inoculated with the Botrytis a few days before, I find less of the normal globules, a considerable quantity of granules, rudiments of thalli, and a quantity of these rudiments in a state of transformation, being intermediate between the rudiment and the animated granule, and still preserving the vital movement peculiar to the latter."

Finally, if a drop of infected blood be placed on the object-glass of the microscope, the rudiments alluded to are seen to extend, ramify in various directions, and at length produce the sporules of the botrytis.

The immense experience of M. Guerin in the habits and conditions of the silk-worm, joined to his well known accuracy as an observer, leave no doubt on the reality of the transformation above described. It is one of the most curious and at the same time important discoveries of modern pathology; for it demonstrates, in fact, what the illustrious Liebig had developed in theory, that disease may be communicated to the blood through the medium of a ferment. Here, however, we advance a step further, and find a ferment not acting on substances analogous to itself, but converting an animal matter into a vegetable one. A single sporule inserted on the point of the finest needle is sufficient to work this wonderful change in the whole mass of the blood within forty-eight hours.

SELECTIONS FROM FOREIGN JOURNALS.

RESEARCHES MADE BY THE AID OF GALVANISM ON THE VITAL PROPERTIES O THE MUSCULAR SYSTEM IN HEALTH AN. DISEASE.

By M. DUCHENNE, of Boulogne.

I.—In a Memoir, extracted from Chapter I. o his Work, and addressed to the Academie de Sciences, he states—

1. Muscular contractility in galvanized paralytic is due to a disturbance of the state of irritability.

2. The disturbance is an organic lesion, not change of conductive force.

II. In the second part he believes himself to have demonstrated—

1. That in certain pathological conditions, irritability almost or quite disappears.

2. That this dynamic lesion coincides sometimes with a paralysis of voluntary movements, as in lead paralysis—sometimes with muscular weakening, as seen in the so-called general progressive paralysis.

3. That often irritability has disappeared from the muscular tissue, while the nervous trunks still preserve the faculty of provoking movement. Hence it is necessary to distinguish irritability from that special property of nerves, designated motricity by M. Flourens.

4. That the loss or diminution of irritability is not always the result of an appreciable anatomical lesion of the nervous centres.

5. Under certain treatments, one often sees voluntary movements, muscular force, and muscular nutrition, restored in all their integrity; while irritability has partially or altogether disappeared.

6. That from this well verified fact, this other capital proposition is rigorously deducible—*irritability is not necessary to motility.*

Hence, the author considers that Flourens' nomenclature above alluded to is correct; and that Cuvier's opinion, as to its being a superfluity of language, is incorrect.—*Comptes Rendus.* 1848. No. 26. P. 779.

CLINICAL REMARKS ON PULMONARY PHTHISIS.

By Dr. GROSHAUS.

In these observations, which embrace a great portion of the history of phthisis, the points which chiefly interest the attention are the diagnosis and the curability of the disease.

The author endeavours to prove that the physical diagnosis of the different forms of induration subsequent to pneumonia, and the tubercular deposition of phthisis, is sometimes altogether impossible. In truth, it may be affirmed, that in a subject with a distinctly marked dulness and absence of the respiratory murmur at the upper region of the lungs, on their evidence alone it would be difficult to determine whether it were a case of simple induration or the accumulation of crude tubercles. At that stage of phthisis there is no characteristic indication offered by the stethoscope, and it is on good grounds that our author affirms, that it is only from a general view of the whole symptoms of the case that an opinion can be delivered on the diagnosis. The same would hold true in the case of a pneumonia of a chronic character attacking a circumscribed portion of the lung. The case reported by our author does not appear very conclusive, for the general character of the symptoms are not so positive. The case was of an individual 34 years old, who had coughed and expectorated abundantly, for a month, purulent matter. He was wasting gradually with nocturnal perspirations. By auscultation the respiratory murmur was clearly developed over the whole anterior region of the chest; but posteriorly, on the level of the left scapula, the sound was perfectly dull, and there was *no* respiratory murmur whatever. At that point the bronchophony was distinct. At the *post-mortem* the right lung was found healthy all throughout, but the lower portion of the left lung was in a state of grey hepatization. Obviously, the wasting of the body, the nocturnal sweats, and the purulent expectoration, led to the apprehension of the presence of tubercles, and, on the other side, the absence of the respiratory murmur, and the dulness at one particular point are the signs which belong to induration. But the author had not reflected on the coincidence of a purulent expectoration, (indicative of deep disorganization of the lung, especially when attended with colliquative signs,) with a simple absence of the respiratory murmur, without the mucous râle, and without the gurgling sound. No such combination of sounds are ever found in phthisis.

As to the curability of phthisis, the author adopts the affirmative side of the question. Nevertheless, he believed that the frequency of the occurrence has been much exaggerated, and that very frequently there were cases of a particular form of pneumonia ending in the formation of small abscesses, the pus of which is gradually absorbed, and calcareous matter substituted. It is, in fact, a form of disorganization of the lung imperfectly noticed in France, and on which Addison, in England, has given some valuable details,—it is the *granulated induration.* It appears that the pulmonary vesicles themselves are not involved in the lesion, but are filled with a solid albuminous substance. On removing a small portion of this matter on the point of a lancet, it is at once apparent that it has no analogy whatever with ubercular matter. The idea of Dr. Groshaus is, hat indurations of this character may become the eat of partial softening, producing small caverns which may be obliterated, either by the adhesion of heir walls, or by the deposition of cretaceous matter, and he supposes that it is in this manner that many pulmonary cicatrices have been reputed as ures of consumption.—*Gazette Medicale.*

CONTRACTILITY OF THE SKIN FROM ELECTRICITY.

M. Brown-Séquard has communicated to the ociété de Biologie the following facts on this subject:—When the scrotum was submitted to a powerful electric current, the contraction of the dartos was very great. The scrotum was immediately and eeply wrinkled. When the electricity was passed hrough the skin, the cutis anserina was produced The hairs became erect, and the hair sacs prominent These phenomena were strongly marked on some aralytics. In healthy individuals their degree was ery variable. The contraction, as in the case of the rganic muscles, came on a little while after the application of the stimulus, and lasted some time after s removal. When applied to the scrotum there was voluptuous sensation and erection of the penis. he ourdan, Müller, Henlé, and others, is ascribed to he employment of too weak a current.—*Gaz. Med.*, ov. 10.

MEMOIR ON THE ANATOMY OF THE CONJUNCTIVA, AS RELATING TO ITS PATHOLOGICAL CONDITIONS AND THEIR TREATMENT.

By M. DE CONDE.

A careful examination demonstrates, in the different parts of the conjunctiva, very well-marked ifferences in its structure, and, on the other hand, e perceive diseases restricted to these particular ivisions or regions, each of them being limited to ne portion of the mucous tissue of the eye, without touching on the ground belonging to another ffection. On this principle the mucous membrane the eye subdivides itself into three parts—the rsal conjunctiva, the reflected conjunctiva, and e ocular conjunctiva.

The first, the tarsal conjunctiva, adheres in all s extent by cellular tissue closed in by the poste or surface of the tarsal cartilages. There are und the meibomian follicles, the secreting organs rheum. There, also, pathologically, is the seat the fleshy granulations, the secondary phenomena f contagious ophthalmia, and which is not necesarily connected with its presence. They are seen, hiefly confluent, on the upper palpebra, about a ne within the adherent margin of the tarsus.

The second portion or region begins about half a ne beyond the adherent border of the tarsus, and ontinues as far as the globe of the eye; it is conected with the soft fat by a very lax cellular tissue. M. Condé has noticed, that a tolerably large vessel, equently the only one that is discovered along the hole range of the palpebral conjunctiva, traverses his division of the membrane, dividing into numerous branches, the terminal subdivisions of which frequently impart to this portion of the conjunctiva a yellowish tint, which is marked from the remaining white of the mucous membrane.

It is this region alone of the conjunctiva, which, in infectious ophthalmia, becomes susceptible of the production of vesicles (vesicular granulations) which distinguish those diseases, never extending beyond it, either to the first or tarsal division, or to the third or ocular. Again, on the other part, fleshy granulations are never found on this portion of the membrane. It differs, accordingly, from the first division, inasmuch as it has not the elements for the fleshy granulations, and by this, that it, and it alone possesses the elements for the vesicular granulations. But, it may be asked, whether these vesicular granulations are a new product, or are they the result of a morbid change effected in a structure pre-existing in the healthy condition of the membrane? M. De Condé has entertained, for a long period, the latter opinion, though he had been unable to demonstrate it anatomically; but, M. Spring, Professor at the University of Liege, stated to him, that in his annual courses of anatomy, he demonstrated their presence in the posterior-tarsal palpebra, in the form of a crowd of little glands scattered over the surface. They are rendered quite apparent to a glass of moderate powers, if the precaution be adopted of softening the subjacent cellular tissue for a short while.

Paying attention to the above precaution, two linear dispositions of small prominent points are noticed like the points of pins, very fine pearls, exactly like small nipples but which in this microscopic condition are represented finally by the granulations termed vesicular. There can be no question, that these are the little glandular or follicular bodies, which enlarging pathologically, and their secretion changed from its usual character, acquiring a special disposition, constitute the vesicular granulation, which distinguishes the ophthalmia, termed military.

As to the third portion, M. de Condé admits its existence, though often disputed. It may, he observes, be separated from the cornea in large plates, simply by macerating the eye in warm water. In pterygion it undergoes a peculiar change, which often is entirely limited to its tissue.

In this membrane there are neither papillæ, or elements for the fleshy granulation, nor little glandular organs, or rudiments for the vesicular granulation. To which last condition, and to the employment of a radical treatment, limited to the palpebral conjunctiva, we are so often able to guarantee the safety of the eye.

ABSORPTION OF CASTOR OIL.

A dose of castor oil was administered to a young man who had received an injury of the back. The next day, no effect having followed the medicine, the patient was bled. On the surface of the blood, received in a basin, appeared little oily particles, and on the following day a complete oily pellicle had formed, which could be removed by the finger. It was quite certain there was no oil in the vessel.—*Il Raccoglitore Medico*, quoted by *Gaz. Med.*, Nov. 10.

SIZE (MAGNITUDE) OF THE EYE AT THE DIFFERENT EPOCHS OF LIFE.

BY M. QUETELET.

The undernoted results, referring to the magnitude of the eye in the horizontal direction, (that is to say, from one angle of the palpebræ to the other,) at the different periods of life, prove that towards five years of age, the eye has in a great measure acquired its full growth, the subsequent increase being very slow, and almost insensible.

Complaints having reached us of the irregular delivery of the MEDICAL TIMES *in the country by the Booksellers and Newsmen, we state, for the information of our readers, that this Journal is always published early on Friday afternoon, so that it may reach the Provinces by post on Saturday morning.*

Correspondents are requested to address their Communications to "The Editor of the MEDICAL TIMES, *147, Strand."*

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, WM. S. ORR AND CO.

THE MEDICAL TIMES.

SATURDAY, NOVEMBER 24, 1849.

THE Board of Visiters appointed by the Michaelmas Court of Quarter Sessions, 1848, to inspect the private Lunatic Asylums in the Bristol District, has brought to light some startling truths. From the Fourth Report of the County Chairman, to the Gloucestershire Trinity Court, held 16th of October last, it appears that some of the worst abuses of the old *régime* still exist in a few of the Institutions established for the reception of the rich insane.

The enormities formerly perpetrated upon persons afflicted with mental alienation, induced the Legislature to pass laws to ameliorate their condition. So far as we can judge from statistics, there are, exclusive of imbeciles, three and twenty thousand persons of unsound mind in this country; and of these, 5,000 belong to the upper and middle classes of society. It is remarkable that, while the condition of pauper lunatics has been greatly improved—while the Institutions appointed for their reception have been placed under such surveillance as to render acts of oppression towards the inmates almost impossibilities—persons in better circumstances, immured in private asylums, may yet be subjected for a long time to serious maltreatment. The grand cause of this is, that private madhouses are generally mercantile speculations; the returns being proportioned to the numbers and resources of the individuals under the care of the proprietors. Hence, it is their interest to receive and to retain as many as possible of the "better classes;" and those patients who pay most are sometimes in the greatest danger of suffering the longest confinement.

The Government, in legislating for those persons, felt it had greater difficulties to contend against than in striking off and for ever the iron fetters which a barbarous age had placed upon the bodies of pauper lunatics. A vigilant inspection would almost to a certainty prevent a repetition, to any great extent, of the cruelties formerly perpetrated in the York Asylum, and in the hospitals of Bethlem and St. Luke, while the poverty of the pauper would insure his emancipation from confinement so soon as his malady was removed. The great difficulty was with persons who had gold at their command—a talisman of such singular powers as to open with facility the doors of private asylums for the admission of patients, but was a formidable barrier to their exit. Hence the necessity of licensed houses—of medical certificates—and of vigilant inspection; yet, with all these, Mammon has triumphed over Mercy, and has laughed to scorn the penalties of law.

Take as examples the Fishponds and Ridgeway House Asylums. At a cost of 1200*l.* to the county of Gloucester, some grave abuses in these establishments have been discovered and exposed. In the former, *strait-waistcoats, hobbles, and muffles, especially for* LADIES, were found to be used, and for a time escaped the notice of the Visiters, because unrecorded by the Superintendent. Here, also, the old-fashioned practice of washing dirty patients in the open air with a mop and cold water was not allowed to fall into disuse; and the principal of this establishment, in the space of eighteen months, had "by his commission of thirteen misdemeanours, and ninety cases, incurred penalties to the amount of 1710*l.*" A Mr. James Drury was illegally imprisoned for twenty years; and for the last four years of his incarceration at the Fishponds was allowed to remain without exercise. A Mr. L. B. was fifteen years in confinement—for ten years not out of doors, because he had not been dressed; "with shirt and stockings on, but without shoes, and with no other clothing but a quarter of a blanket tied round his shoulders, and another quarter round his loins—his beard unshaved and untrimmed." In this condition he remained till April of the present year; when at length, having been shod, clothed, shaved, and compelled to take exercise, he so rapidly regained a healthy tone of mind and body, that his friends removed him to their own home.

At the Ridgway-house there were no fixed baths; and a moveable one, discovered by the Visiters, had been selected by a hen wherein to make her nest and deposit her eggs. A gentleman named Hayward, "strong in body and sound in mind, as many witnesses can testify," was locked up in a bed-room in Ridgway-house for nearly four weeks, being only allowed, occasionally, to take a little exercise in the garden with a keeper. During this time, he had administered to him powerful medicine, and having no access to a water-closet, the stench in which he lived is described by witnesses as having been intolerable.

Such gross acts of injustice and cruelty as have been perpetrated in these Private Lunatic Asylums, go far to prove that the laws now in existence in reference to persons charged with insanity, need revision. A Medical Man, being proprietor of a private mad-house, has an authority which a non-professional person cannot possess. This very authority may be the means of perpetuating some of the worst abuses the law has sought to annihilate; and we have no better proof than in the cases before us. In all establishments, no matter who the proprietor, there should be a Medical Superintendent, having access to the patients at all times, responsible only to the Commissioners or Magistrates. This, with active visiters, may eventually remove those barbarous practices which originated in a dark age, and have been perpetuated by cupidity. The upper and middle classes of society claim especial protection, for psychological science is becoming so refined, that a peculiar religious opinion, a single eccentricity in conduct, or nervous irritability, may be viewed as unequivocal proof of madness, and the individual in whom it is manifested forthwith confined in a private asylum, it may be, for life. But, supposing an individual really insane, and that it is necessary to place him in an asylum, psychological science affords no pretext for exercising towards him mechanical violence. Pinel, Conolly, and other illustrious Physicians have entered their protest against it, and experience has proved that their views are correct. It is true, that in the Royal Asylum of Charenton, and in some other French hospitals, strait-waistcoats, coercion-chairs, and bed-straps are still used, but the consequence is, that there suicide is a frequent occurrence; while at Hanwell, where the non-restraint system has been in operation for some years, the happiest results have followed.

The Commissioners in Lunacy cannot overlook so important a document as that which has just been published by the Chairman of the Board of Visiters appointed to inspect the private Lunatic Asylums in the Bristol district. We shall immediately return to this all-important subject, and endeavour to illustrate, in more than one Editorial Article, the defective state of the Law of Lunacy, which the Legislature must endeavour to improve.

REFORM IN THE COLLEGE OF SURGEONS.

THE first-fruits of a more liberal constitution of the Council of the College of Surgeons have been exhibited in the Resolution to apply to the Crown for an amendment of the Charter of 1843. The members of the College will accept this concession as an instalment towards the redress of those grievances of which, for upwards of half a century, they have complained. We are not surprised at this demonstration of a returning sense of justice on the part of the Council, nor shall we be much amazed if this step should prove merely initiatory to a more comprehensive reform of the Profession, upon a basis that shall sustain the dignity of the Colleges, whilst it upholds the indefeasible rights of the members. That the mere admission to the Fellowship of members of the College of twenty years' standing will be received as the ultimatum of the Council on the broad question of Medical Reform is not probable, although, so far as it goes, and considered simply in the light of an improvement in the internal organization of the College, it will give satisfaction to numerous gentlemen who feel grieved and indignant at the unmerited exclusion from corporate rights and honours under which they now suffer. Even those gentlemen, however, who hope thus to be indemnified for past wrongs, must not consent to be lulled into supineness by the expectation of this small boon, for it is not impossible that the minority of the Council may exercise a more powerful influence with the Government than could be exerted by a vote of the majority, however large. There is a wide chasm between the application for a Charter and the grant of it.

We cannot refrain from pointing out, that the

admission to the Fellowship merely entitles the Fellow to a vote in the election of Council; but, if he practise midwifery and pharmacy, he is still excluded from the higher offices of the College. Besides, the admission to the Fellowship will, in all probability, be clogged with so many restrictions, even upon those whose standing ought to give them an unqualified title to this rank, that it will be regarded by many rather as a new imposition of pains and penalties than as a liberal acknowledgment of their legitimate claims. Nevertheless, whilst we see many objections to this measure, in its more limited aspects, we are disposed to receive it with goodwill, and to judge favourably of a Council that shows an inclination to repair the mischief and injustice of many years of past misrule. It may be that the majority of the Council feel it necessary to move with caution in the new path they have described for themselves, and that they feel some timidity in the exercise of their unwonted functions; for assuredly it is something new for the Council of the College to engage in the career of medical reformers. They have not yet acquired an aptitude for the work, and the gentle virtue of diffidence becomes their unpractised hand. Success will make them bolder; and, although we must confess that we are unused to the language of panegyric, we feel, on this occasion, a very impulsive disposition to celebrate their generosity in eulogistic strains, if only to show them, by the measure of our gratitude for small gifts, how greatly grateful we should prove for larger benefactions. We would encourage them in their new undertaking; for none are so much inclined to do better as those who are already pleased to think that they have done well.

There is wide scope yet for reform, and we think that it is the duty of the College of Physicians to step forth and vindicate its right to preside over the Medical practice of this country. The excessive poverty of this College reduces it in the eye of the Profession, and limits its usefulness. Whilst this College can hardly collect 1200*l*. per annum, the revenues of the College of Surgeons are 12,000*l*. The rivalry is unequal, and unless the College of Physicians *do* something for the progress of Medical science, it will in a few years cease to be honoured. It is manifest, that unless its funds be increased, its sphere of action will remain too contracted to retain for it, as a College, a station of becoming dignity among the Medical Institutions of this country. The College, if it be wise, will throw open its doors; there are many waiting to come in, whose attainments and social position would not dishonour this venerable and aristocratic body.

We observed, in an advertisement in our last week's Number, a notification that a Conference was about to be held on the subject of Medical Reform, at the Hanover-square Rooms, at the invitation of the Council of the National Institute; and we trust that the deliberations of this assembly will tend to harmony of opinion among all classes of reformers. There can be no doubt that the activity and vigilance of the Institute have been highly serviceable to the cause of the General Practitioner.

A notice of this meeting appears in another column.

ON THE SUPPLY OF SUBJECTS FOR DISSECTION.

It is with great regret that we can announce no improvement in the opportunities afforded to this year's students of acquiring a competent knowledge of the anatomy of the human body. We had hoped that the stir made about it last session, and the fact, that the attention of the College of Surgeons was then forced to this subject, would have led to some real and permanent improvement. The investigation, however, ended as usual in nothing, and the College contents itself with demanding a full knowledge of Anatomy from the Candidates for its Diploma, without paying attention to the obvious fact, that no student has a chance, however much he may be inclined, of acquiring such knowledge, at least in this country.

In Paris, we believe, the price of subjects varies from three to nine or ten francs, according as they may be injected, &c. In London a subject costs four pounds, and, even at this price, students have to wait perhaps for weeks or months before they can get an extremity. We fully believe, that at the Metropolitan schools there is not received, during the whole session, more than one subject, on the average, for every four students!

Can we be astonished, then, that on the whole our Medical men are far inferior to those of France in their knowledge of Anatomy? Ought we not rather to wonder how they contrive to acquire the amount of information they have? Ought the Colleges to be surprised at the frightful ignorance so frequently displayed at their examinations? Is the fault with the students? Ought the punishment to be visited on them? We answer—No. Give every student ample means of acquiring a full and practical knowledge of the structure of the body, and then require, strictly and sternly, a proof from him that those means have not been wasted or misapplied.

We believe that one anatomical teacher proposed, shortly before the commencement of the present session, when cholera was raging, that the body of no person who had died of that fell disease should be received for dissection at any of the London Schools. The proposition was immediately negatived, for it was felt that such fastidiousness was inopportune; that, let the subjects come from what quarter they would, or die of what disease they might, they were too precious to be rejected, and must be most thankfully received.

It is obvious that such a state of things should not, cannot, be permitted to last. There must be a fault somewhere. In so large a town as London, with such an amount of poverty, and so great a weekly mortality, the supply of subjects ought to be as abundant as in Paris, even though the expense be greater.

If London, then, is to retain its former reputation as a great school of Medicine and Surgery, it behoves the various lecturers and teachers to combine forthwith with the different Colleges, for the purpose of first determining the source of the mischief, and then of finally and completely correcting it.

Would that we may soon be enabled to inform our readers that our hopes and wishes have been realised.

THE REPORT OF THE CITY OFFICER OF HEALTH.

The Report of the City Officer of Health was on Wednesday discussed by the City Commissioners of Sewers, and by them referred to the Committee of Health, "to take into consideration the course to be adopted thereupon."

The real import of the meeting, of course, consists far less on this formal act of reference than in the discussion which preceded it, and which may be regarded as indicating, in some respect, both the opinion and the probable conduct of the Corporation of London.

On the whole, so far, so good. For the Report comes out of the furnace of discussion quite unscathed: its facts remain unchallenged, its recommendations furthered by a theoretic approval; and even in spite of their presumed impracticability, there clearly is a strong disposition to do something towards their fulfilment. There must and will be progress, in one or more of the directions suggested in the Report.

The dissentients,—clearly in the minority, both of numbers and of importance,—were so completely and specifically answered in the meeting by other members of the Commission, that refutation becomes unnecessary. One well-known opponent of Sanitary Reform seems rather to approach the rancorous; but when argument is deficient, personal hostility forms a ready, if not a creditable, substitute. It is difficult to gather precisely what happens in a stormy discussion; but we incline to think the Court showed scarcely sufficient anxiety to protect their officer in the discharge of his duty, from the impertinence of the person alluded to.

TYPHUS FEVER, TYPHOID FEVER, RELAPSING FEVER, AND FEBRICULA,

THE DISEASES COMMONLY CONFOUNDED UNDER THE TERM

CONTINUED FEVER.

ILLUSTRATED BY CASES COLLECTED AT THE BED-SIDE.

By W. JENNER, M.D. Lond., Professor of Pathological Anatomy, University College; Assistant Physician to University College Hospital, &c.

(Continued from page 405.)

In my last paper were detailed four cases of uncomplicated typhus fever, which, I stated, might be regarded as models of that disease. I shall, in the present paper, give a general description of typhus fever in its severe form, reserving till the next a consideration of the special symptoms on the varying severity of which the modifications the disease exhibits chiefly depend.

GENERAL DESCRIPTION OF THE SYMPTOMS AND PATHOLOGICAL APPEARANCES OBSERVED IN TYPHUS FEVER.

Typhus fever attacks persons of both sexes and of all ages, from early infancy to extreme old age.

After a few days' trifling sense of languor, or slight malaise of mind and body, the patient is seized, more or less suddenly, with rigors and chilliness, usually followed by heat of skin, and occasionally by sweating; pains in the back and limbs, and frontal headache. The rigors and sense of chilliness are in many cases repeated, at irregular intervals, for two or three days. The patient hovers over the fire one hour, although his skin may at the time feel hot to his attendant, and the next hour complains of the heat of the room; or

when near the fire feels hot and oppressed, when away chilly and uncomfortable. The appetite is lost, and there is frequently more or less thirst from the outset; the tongue is white, large, and pale, and often slightly tremulous;(a) the bowels confined or regular; the urine rather scanty and high-coloured; nausea and vomiting are often among the earliest symptoms. There is total want of sleep, or, on the contrary, heaviness and drowsiness. Sleep, if it occurs, disturbed by dreams, or interrupted every few minutes by sudden starts, is unrefreshing. The sick man frequently declares that he has "not had a wink of sleep," when those watching testify that he has slept for hours.(b) Unable to think or to fix his attention, he feels "downright ill," and so extremely weak, that, however pressing the calls for his exertion, the patient usually takes to his bed by the second or third day, and not unfrequently on the first. There is both absolute loss of muscular power, and an almost intolerable sense of exhaustion; the latter being at first, perhaps, out of proportion to the former. Vertigo and noise in the ears are frequently among the earliest and most loudly complained of symptoms, especially the former. The debility increases rapidly, so that by the seventh day the patient can rarely leave his bed without some assistance. By this time, if not before, the muscular movements are unsteady, the raised arm shakes, and the protruded tongue trembles. The inability to fix the thoughts soon passes into defect of memory; (c) this into delirium, at first between waking and sleeping, then by night; and finally by night and day. When delirium first sets in, the patient is able to correct himself, *i.e.*, on thinking he becomes conscious of his mental error, but this power is soon lost, and he believes in the existence of all the phantasms his imagination conjures up, or his erring senses paint.

The headache ceases on from the 7th to the 10th day of disease; if not before, almost invariably as soon as delirium commences (d).

About the fifth or sixth day an eruption appears on the skin; at first consisting of numerous roundish, slightly elevated, dusky pink spots effaceable on pressure by the finger, quickly resuming their colour, however, when the finger is removed; on the second or third day after their appearance these spots, instead of being effaced, merely fade, *i.e.*, grow paler, on pressure. At the same time, with the spots referred to, there is present a much paler rash, which appears to be seen through the cuticle, as if the spots composing it were, as the vulgar say, "not well out." The latter is the subcuticular rash, the whole eruption the mulberry rash. (a) The skin throughout the course of the disease is often particularly sensitive, the lightest touch occasioning pain. At the termination of the first, or at the commencement of the second week, the tongue grows dry in the centre, and at the same time its white fur is replaced by pale dirty brown mucus. Usually about the ninth or tenth day, but sometimes much earlier, the delirium becomes decided, although the attention may still be fixed by a sharp question. At this time the patient is in some cases violent, and, unless restrained, leaves his bed to wander about the room. The expression, which at first was simply indicative of langour, weariness, or of a semi-drowsy condition, resembling that of a man unwilling to be aroused from half drunken slumbers, is now that of complete stupidity and decided prostration. The complexion, which from the first, was thick and dirty, in the course of the second week becomes absolutely muddy; the conjunctivæ injected, and the pupils contracted. The face is now often flushed, the flush being dingy and pretty uniform over the whole face; occasionally, however, somewhat more marked on the cheeks than elsewhere. The eruption grows darker in hue, the centre of many of the spots towards the termination of the second week, are unaffected by pressure, and here and there are to be seen some spots with well-fined outline, quite unalterable in appearance by the firmest pressure of the finger, *i.e.*, true petechiæ. The posterior surface of the trunk is considerably congested, and the spots are there much darker and less affected by pressure than on the anterior surface.

About the 10th or 11th day, somnolence sets in and gradually passes into stupor and even coma, when the expression indicates profound prostration. The patient lies on his back unable to turn or assist himself in the slightest degree, and the urine is often passed involuntarily, or is retained, requiring the use of the catheter for its removal. The tongue is thickly coated, dry and dark brown, or even black, appearing as if baked; perhaps unable to be protruded; the teeth are covered with sordes; the patient is unable to be roused for more than a minute or two and then mutters incoherently; the conjunctivæ are intensely injected and the pupils contracted; the skin is cool, and occasionally moist; miliary vesicles, or sudamina, are sometimes observed about the end of the second week; usually in the groins, at the epigastrium, and under the clavicles.(a) The abdomen continues flaccid and indolent throughout. The bowels usually act once or twice a day, the stools being somewhat relaxed.

The pulse, from the outset of the disease, is quickened, and it increases in rapidity until the disease terminates fatally; or, after reaching a certain point, its frequency as gradually subsides till health is restored. A little cough and some sonorous râle are now and then present.

The disease generally terminates, if it proves fatal, from the twelfth to the twentieth day,(b) before death the prostration increases to the last degree; *subsultus tendinum*, or perhaps involuntary twitching of the muscles of the face and arms make their appearance; the face becomes dusky or even livid; the breathing very quick; the pulse so rapid and feeble that it can scarcely be felt, or, it may be, quite imperceptible; some want of resonance of the most depending part of the chest may often be observed at this stage of the disease; the respiratory murmur at the same part appears muffled, as if heard through a thick veil, and there is sometimes a little coarse unequal crepitation. The urine, which is secreted in large quantities—from three to four pints daily,—is retained, or passed into bed with the stools involuntarily. The skin, at this time, is often bathed in a profuse sweat, the temperature being below the natural standard; the spots are scarcely, or not at all, affected by pressure, especially on the dorsum; the whole skin of the posterior surface of the trunk is deeply congested. The patient lies on his back unable to move, or he sinks, if his head be at all elevated, towards the bottom of the bed. A slough frequently forms about the middle or the end of the second week on the lower end of the spine or on the posterior spine of the ilium.

(a) The early loss of mu ular power, of which the tremulous tongue is one xample, is a symptom of grave import so far as c icerns the prognosis. In no disease is the effect c previous habits of intemperance more clearly en, in causing muscular tremors, than in typhus ver.

(b) This fancied wa hfulness has been erroneously termed coma vigi

(c) It is a singular fact, that the patient invariably supposes time to be prolonged; thus, if taken ill on a Monday, he will say, on the Monday succeeding, that he has been ill ten or twelve days, or perhaps weeks, and never assert that his illness has lasted only four or five days. At the same time he may, and generally does remember the name of the day on which he was taken ill, or on which any given event happened. If the medical attendant tells the patient that any given day is Wednesday, if he asks, at his visit on the following day, "How long is it since you saw me?" the sick man will probably answer, "three or four days;" but, if he ask, "On what day did you see me last?" he will probably be answered correctly, "on Wednesday," especially if any event occurred at the first visit to make an impression on the patient.

(d) This is a point of great practical importance, for if headache is voluntarily complained of by the patient, or even if declared to be severe in answer to the question of the physician, after delirium has commenced, strong suspicions, to say the least, of inflammatory action within the cranium should be entertained, and remedies adopted in accordance with that view of the case. While headache, before delirium has commenced, is in itself not the slightest proof of increased vascular action within the cranial cavity.

(a) As a clear perception of the characters of the eruption in typhus fever is of the highest moment in forming a diagnosis, the reader's attention is especially directed to the following particulars:—Seen on about ninth day, the patient in a well-marked case of typhus fever appears covered with a dusky red rash, having somewhat the hue of mulberry stains. On more minute inspection, and careful watching from its commencement to its disappearance, the rash is found to be divisible into two parts.—

I. DISTINCT SPOTS.

Each spot passes through three stages.—*First stage.* —On their first appearance the spots have a dusky pinkish hue, and are very slightly elevated. They vary in size from a point to three or four lines in diameter. They are somewhat flattened on the surface, and have an irregular outline. They have no well-defined margin, but pass insensibly into the hue of the surrounding skin. They disappear on pressure, but resume their characteristic appearance as soon as the pressure is removed. The largest spots appear to be formed by the coalescence of two or more smaller, and the shape of the former is, as a consequence, more irregular than that of the latter *Second stage.*—In from one to three days the spots undergo a marked change; they are no longer elevated above the level of the surrounding cuticle; their hue grows darker and more dingy; and instead of disappearing, they only fade on pressure, *i e*, when the finger is firmly pressed on them they grow paler, but do not entirely disappear. In some cases the spots, after reaching this stage, pass into very faintly marked, reddish-brown stains, and then disappear *Third stage.*—In other cases the spots reach a third stage; their centres become dark purple, and are unaltered in appearance by the firmest pressure, although their circumferences still fade; or the entire spots, circumference as well as centre, change into petechiæ.* A few may be found in the third stage, while the majority are in the second.† The spots are generally very numerous on the trunk and extremities, but occasionally there are very few. They are rarely seen on the face. Their number reaches its maximum on the second or third day at latest. Each spot remains from its first eruption till the disease terminates, excepting a few large almost scarlet patches, occasionally seen on the back of the hand, on the fifth or sixth day of the disease, which usually disappear altogether in a day or two.

II. THE SUBCUTICULAR RASH.

When the rash is very abundant, usually many of the spots are pale, imperfectly marked, and run into each other; these spots are seen indistinctly, as if situated beneath the cuticle. They often give to the skin a mottled aspect, and on this mottled surface, which I have termed the subcuticular rash, as on a ground, the darker, more distinct spots are situated.

The appearance of the rash in typhus fever varies, then, according to the number of the spots, their stage, the abundance of the subcuticular rash, and the depth of colour of either. Sometimes there is present only a faint subcuticular rash, sometimes only a few well-marked spots, or again, the subcuticular rash may be abundant, the well-marked spots few in number, or the latter may be very numerous, and the former all but absent. For the whole eruption I have elsewhere (see *Monthly Journal*, April, 1849) proposed the term *mulberry rash*, and by that term I shall designate the eruption characteristic of typhus fever in these papers.

* By petechiæ I mean spots not elevated above the cuticle; of a dusky crimson or purple colour, quite unaffected by pressure, with well defined margins.

† I have sometimes observed the spots to possess the characters of the second or third stage on their first appearance.

(a) My impression is, that sudamina are rarely if ever, seen on patients more than fifty years of age.

(b) The question of critical days is not here considered. It requires for its solution a most careful analysis of numerous fatal and non-fatal, complicated and uncomplicated cases. The uncomplicated cases must evidently be analysed separately from the complicated, because the latter are often protracted long after the fever has run its course, or are cut short by the severity of the local disease almost irrespective of the fever. Ordinary hospital records, from the little trouble taken to fix the day on which the disease commences, are obviously of no avail in settling a question of so much delicacy as the one to which I here refer.

Occasionally, for a day or two before the fatal termination of the disease, the condition, termed coma vigil is observed.

A person labouring under coma vigil presents a very peculiar appearance. He never sleeps. He lies on his back, with his eyelids widely separated; his eyes staring, and fixed on vacuity; his mouth partially open; his face pale and expressionless. He is totally incapable of being roused to give a sign of consciousness; the breathing is often scarcely perceptible; the pulse rapid and feeble, or unable to be felt; the skin cool, perhaps bathed in perspiration. Life is only known to have ceased by the eye losing its little lustre, and the chest ceasing its slow and feeble movements. I have never seen recovery from absolute coma vigil.

If, instead of death, the disease terminates in recovery, the improvement in the condition of the patient is frequently sudden. On from the thirteenth to the seventeenth day he falls into a profound quiet sleep, and after from twelve to twenty-four, or even more hours, awakes decidedly improved in all respects. The complexion is clearer; the delirium has disappeared; the pulse fallen in frequency; the conjunctivæ are no longer injected; the tongue is moist at the edges; there is perhaps a little appetite; the skin is softer; the spots paler; the general powers improved. In a few days the tongue cleans, the appetite becomes ravenous, and the patient rapidly regains strength.

APPEARANCES FOUND AFTER DEATH FROM UNCOMPLICATED TYPHUS FEVER.

The cadaveric rigidity disappears shortly after death. The posterior surface of the trunk and extremities are of a deep port wine colour; the abdominal parietes rapidly assume a greenish hue, and the course of the large superficial veins in the neck, arms, and lower extremities, is often marked by lines of a dusky, dirty violet colour. If miliary vesicles formed during the last days of life, they are still seen.

On the surface of the trunk and extremities are und the remains of the spots noted during life. the spots were before death rendered paler on pressure, they are less distinctly marked, and have a less deep hue than during life; if they were unaffected by pressure, they retain the exact appearance they presented before death. Those on the most depending part of the subject are by far the deepest in hue.

If a portion of the skin is removed and examined with a lens, the persistence of the spots, which faded or grew paler on pressure, is found to be due to staining of the surface of the cutis; while the whole of that texture, and even the subcutaneous tissue, is dyed deep purple, in those spots which were unaffected by pressure during life.

There is usually a moderate amount of serosity beneath the arachnoid and in the meshes of the pia mater; and considerable congestion of the latter membrane, especially between the convolutions. The sinuses and larger vessels are filled with dark fluid blood. The arachnoid and pia mater separate with abnormal facility, and in much larger portions than natural, from the convex surface of the brain. Both membranes may generally be removed in an unbroken mass. The red points in the grey and white substance are rather more numerous, and larger than is usual after death from other diseases. The amount of fluid in the lateral ventricles and at the base of the brain is slightly increased. The consistence of the brain is nearly natural.

The pharynx and larynx are normal. The œsophagus is healthy, but its epithelium is found in a great measure detached. The mesenteric glands retain their normal appearance. The mucous membrane of the cardiac extremity of the stomach, nay the whole of its coats in that part, are frequently softened, and the entire lining membrane is smooth, presenting but few rugæ; in other particulars, the organ appears to possess the characters of health. The intestines, large and small, are normal in colour, thickness, and consistence; the liver moderately congested and flabby; the pancreas in a similar condition; the spleen varies somewhat in its state according to the age of the subject; before forty-five or fifty it is usually much enlarged; after that date it is still often enlarged, but not so decidedly as in the earlier period of life. Softening of the organ appears to follow the reverse order, as it is softer in aged than in young subjects. The kidneys are congested and flabby, and the epithelium lining the tubes of their cortical substance separates from the basement spontaneously very shortly after death. The bladder is healthy, but a little turbid fluid is frequently formed in it; the turbidity is owing, in many cases, to a separation of the epithelium covering the mucous membrane of the organ. The heart is particularly flabby; its contents are either fluid, or loosely coagulated black blood, and a small soft fibrinous clot stained reddish violet. The lungs are intensely congested posteriorly, and occasionally solidified at the same part. The solidified portion being that which, in the recumbent position, is the most dependent; the distance it extends into the lung varies from ½ to 1½ inch. It is tough, non-crepitant, non granular, and contains much dark reddish serosity. The crepitant portions adjacent are generally gorged with reddish frothy serosity. The bronchial tubes usually contain much frothy mucus, and their lining membrane is considerably congested. The bronchial glands appear healthy. The peritoneum pleuræ, and pericardium are normal in all particulars; but, if the examination after death has been delayed, the last contains some red serosity this red colour of the serosity is the consequence of transudation of a solution of the colouring matter of the blood. Large patches of epithelium may be detected by the microscope floating in it, but *no* blood-corpuscles.

[To be continued.]

REVIEWS.

Confessions of a Hypochondriac; or the Adventures of a Hyp in Search of Health. By M. R. C. S. Saunders and Ottley. 1849.

The object of this Work is, in the words of the Author, "to expose the follies of the hypochondriac and the crying evils of quackery;" and, although he has in some instances overshot his mark, he has, on the whole, succeeded in the attainment of his end. His book is a fair, if not talented, *exposé* of both, and cannot fail to amuse and instruct the general reader. The Author gives us an account of his early history, which tends to interest the reader in the subsequent narrative. On his father's death, he is obliged to sell an entailed estate and study medicine; he commences practice in his native city, but soon finds the truth of the aphorism, that 'a prophet has no honour in his own country." He pictures his disappointment and is on the brink of despair, when a rich relation dies leaving him a large fortune invested in a Liverpool mercantile house. He now exchanges his lancet for a pen, and his study for a counting-house. After forty years of toil he retires, travels, and returning fatigued, and free from the excitement of business, he becomes *ennuyé*, in short, a Hyp, and, as such, the natural victim of quacks and visionaries. He commences, like all of his genus, by consulting legitimate physicians, or, as they are now called, by way of further distinction, allopaths, and he gives a graphic description of the proverbial difference of opinion for which this learned body has ever been famous. One told him to resume his occupation of wares and merchandise; another, that the worry of trade had overstrained his nerves and exhausted their tone, and that he must have rest; and a third advised him to travel, the *dernier ressort*, we have reason to know, of many a fashionable M.D., when he wishes to get rid of his patient. At last he went to Bath, where the spa-physician, as a matter of course, tells him to employ the waters. Now, this is no uncommon case; there is not, we will venture to say, a physician of any experience who has not met with many such. If the love of life is sweet, the love of health is strong. Can we wonder, then, that the sick man, confounded and perplexed by the contending opinions expressed by those who are called *eminent* in the faculty, should at last lose faith in them, and embrace the first species of empiricism recommended to his notice. In these systems, be it observed, there is at least consistency; and this consistency gives birth to faith, and that faith, acting on the body through the medium of the mind, worketh marvels;—for example, the Homœopath sticks to his globules, and the Hydropath goes not beyond his cold water; but Dr. A gives physic; Dr. B recommends employment; Dr. D, repose; and Dr. E, travel. We affirm, that it is by these practices that quacks prosper,—that it is the crotchets of some of our professional brethren which increase the resources of the Chancellor of the Exchequer. But, to return to our author. He goes through all the phases of quackery, from the wet sheet to the magic bed; he tests the disciples of Hannehman and Preistnitz—the "infallible Goss and Co.—the unctuous Holloway and Lord B's accomplished Baron—the gouty Snooks and the bilious Scott—the life-prolonging Parr and the anti-bilious Frampton—the mysterious Widow Welch, and the incredible Dr. Locock—in all of whom," says he, "I found I had mistaken my confidence."

Within the limits of a short notice it would be impossible to follow the Hyp into the scenes which he describes during the period of his probation; suffice it to say, they are natural, and, although a certain vein of causticity, rather than satire, runs through the whole work, the style and language are free, mild, and gentleman-like. Before bidding adieu to the Hypochondriac, we would particularly direct the attention of our readers to the fourth Chapter of his work; it is on quacks and quackery, and enters into the question of the law in this country, with regard to the existence of the one as permitted, and the spread of the other, as encouraged by the Legislature. We would wish to quote largely from this Chapter, agreeing, as we most thoroughly do, in its sentiments and arguments, but our space prevents

In justice to the Hypochondriac, we cannot refrain from placing a few of his sentiments before the public:—

"The grand distinction between a physician and a quack is this, you may die with the one, but the other will be very likely to kill you. There is a sensible difference between dying and being killed, and of this the fraternity are conscious. A quack called on a physician. 'What is the matter,' said the latter, 'thy pulse trembles, thine eyes glare with terror?' 'I fear I shall die,' said the other. 'I have had the misfortune to take some of my own pills.'"

In talking of the state of the law regarding empirics—different in this country—shamefully different to what it is in any other, he says:—

"Sir James Graham's Bill provided no penal restriction for the unlicensed pretenders whose industry helps to overfill the unions, to gorge the gaols, to burden hospitals and charities with the incurable of deaf, halt, and blind, and to sink the immense sea of beggary which presses down every rank above it—industry, property, and talent, nearer and nearer to its own level of despair. A Bill without a penal clause to touch the traffickers in gullability and humbug would be a plague spot on the most philanthropic session. . . . . The Government derives a revenue from secret remedies and nostrums, and yet Morison has been prosecuted. The State permits the empirics to practise generally, but provides against the possibility of paupers in unions, felons, sailors, soldiers, and lunatics, falling into the hands of the unlicensed and unskilful."

What a paternal Government is ours! Legislators of St. Stephens read, mark, learn, and inwardly digest the above. And should you want further proof of the crying evils of quackery, as fostered by the laws of this country, read the rest

of this Chapter, from which we shall quote one more paragraph.

"It is in the nature of things that an evil is overlooked, as the Tooting and burial infamies were, till the monstrosity has grown large enough to excite public indignation! Then it is crushed. It will be thus with quackery; it will levy contributions and trick the innocent, till the public eye can be no longer blinded to its infamy. The Legislature will lie dormant till goaded into action *ab extra*. In the meantime quackery drives a thriving trade, and the public is genteelly cheated and poisoned."

The Results of all the Operations for the Extirpation of Diseased Ovaria by the large Incision. By Charles Clay, M.D. Manchester. 1849.

We take blame to ourselves for not noticing this reprint at an earlier period, but we thought the Surgical Profession had abandoned the operation. The great Leviathan of Surgery, (or of cutting,) Liston, used to call it, in his Lectures, *abominable* Surgery, instead of Abdominal Surgery; and, in his last work on Practical Surgery, 4th edition, 1846, he says, "Some of the individuals subjected to this process have got over the shock of the so-called operation,—some have lingered for a few weeks, and then died,—a few have miraculously escaped with their lives." Lizars of Edinburgh, who performed the operation, and published a large work on the subject—and than whom there is no better authority—comes to the conclusion, in his "System of Practical Surgery," that "Extirpation of the ovary has not obtained the approbation of British Practitioners, and therefore need not be described."

The diagnosis between a tumour of the uterus, and a diseased ovary, is scarcely practicable; the extent of the adhesions of an enlarged ovary, it is impossible to foretel; the number of blood-vessels extending from the contiguous viscera, as the great omentum, to the diseased ovary, is uncertain; lastly, the magnitude of the pedicle and its vascularity cannot be ascertained:—we should pause, therefore, before undertaking so uncertain and so formidable, if not generally fatal, an operation. Our Author himself encountered all these obstacles; sufficient we should have thought, to have induced him to abandon the operation. For example, he says, that Mrs. Dillon, who died after the operation, had "not an ovarian disease, but a tumour of another and widely different character,—one that would very soon have destroyed the patient." In the same individual, he found "the whole anterior surface of the tumour so adherent to the peritoneum, that to remove the mass was quite impracticable;"—"the character of the tumour was evidently of a very different character to the generality of ovarian tumours; it appeared highly vascular."

In the case of Hannah Edge, the adhesions were equally numerous, and she lost a large quantity of blood. In Mrs. Hardy, the pedicle extended from one fallopian tube to the other, and "the greater part of the uterus itself formed a part of the tumour," "the whole attachment being highly vascular,"—a graphic description of fainting and sinking follows, and she died in an hour and a half after the removal of the tumour. We understand a similar catastrophe followed this operation in a young lady of Edinburgh, operated on by Dr. Clay within the last twelve months.

We are of opinion, that the cases recorded by our Author warrant Liston's observations on the operation, and that few surgeons will be induced to follow Dr. Clay's footsteps.

A New Disease.—The American Correspondent of the *Times* announces, that a new and terrible disease, called the "bobo," has appeared at Vera Cruz. It is represented as being more fatal than the cholera.

REPORTS OF SOCIETIES.

THE NATIONAL INSTITUTE.

THE CONFERENCE AT THE HANOVER-SQUARE ROOMS.

A numerous and highly influential meeting of delegates from the various voluntary bodies associated for the purpose of reforming our Corporate Institutions, was held last Tuesday at the Hanover-square Rooms. Mr. Clifton, of Islington, vice-president of the National Institute, was called to the chair, and explained to the meeting the course the College of Surgeons had pursued at the Conferences at the College of Physicians; he stated, that the obstruction to a settlement of the medical question was the opposition offered by that College; and he especially reprobated the conduct of the College in disavowing the acts of its delegates. The Chairman then adverted to the report that it was the intention of the Council to apply for an amendment of the Charter of 1843, upon the principle of admitting to the privileges of the Fellowship, under certain restrictions, the members of twenty years' standing, and stated that it was for the consideration of this meeting, whether such a concession would satisfy the members, and also what steps should be taken, with reference not only to the proposed amendment of the Charter of the College, but also with regard to the general question of Medical reform. This meeting had been called together by the Institute in order to assimilate, by discussion, differences of opinion, and to induce unity of action among the various classes of Medical reformers, and he was gratified to see so large a number of gentlemen from all parts of the country assembled on this occasion.

Letters were read by Mr. Ross, from Dr. Hastings, President of the Provincial Association; Dr. Kidd, Regius Professor of Physic of Oxford; Mr. Peploe Cartwright, Secretary of the Shropshire Association; and Mr. Bowring, the Secretary of the Manchester Committee of Surgeons, and from many other gentlemen. Mr. Bottomley, the Chairman of the Associated Surgeons, was present, as were also several graduates of the Scotch Colleges, and Mr. Bowling, of Hammersmith; Mr. Propert; Mr. Merriman, of Kensington; Mr. Bird; Mr. Farnham Flower, of Chilcompton; Mr. Donald Dalrymple, of Norwich; Mr. Ancell; Mr. Gibson, of Ulverstone; Dr. Hodgkin, the Chairman of the Committee of Poor-law Medical Officers; Mr. Thomas Martin, of Reigate; Dr. Webster, of Dulwich, and many other gentlemen whose names we could not ascertain.

A most interesting discussion ensued upon the important question of an amendment of the Charter of the College of Surgeons, and it was ultimately agreed, with the unanimous assent of the assembled delegates—

"That a Deputation from the Conference be appointed for the purpose of ascertaining the extent of the concessions proposed to be granted by the Council of the College of Surgeons, in the amendment of the Charter of 1843; also, to submit to the Council the substance of the memoranda as now read by Mr. Bottomley, on the subject of a reform of the constitution of the College of Surgeons, and such other points in relation thereto as may be considered expedient, and that they report the result to an adjourned meeting of the Conference."

The following gentlemen were appointed members of the Deputation:—

Nathaniel Clifton, Esq.; John Propert, Esq.; George Bottomley, Esq., Croydon; Richard Southee, Esq., Cambridge; Henry Ancell, Esq.; D. Dalrymple, Esq., Norwich; James Bird, Esq.; F. Flower, Esq., Chilcompton; Peploe Cartwright, Esq., Oswestry; Dr. Webster, Dulwich; Thos. Martin, Esq., Reigate; Peter Hood, Esq.; John Bowling, Esq., Hammersmith; and Thomas H. Smith, Esq., St. Mary's Cray.

It was also resolved—

"That, should the answer of the Council of the College of Surgeons be unfavourable, the same Deputation do wait on Sir George Grey, to urge upon the Government the importance of an immediate incorporation of the General Practitioners into an independent College, and the passing an Act of Parliament to settle the great question of Medical reform."

The meeting then adjourned to another day, when they would receive the Report of the Deputation.

We shall give a fuller report of subsequent meetings of the Conference, as they are held.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

November 13, 1849.

Dr. Addison, President, in the chair.

HISTORY OF A CASE OF FOREIGN BODY IN THE RIGHT BRONCHUS: WITH REMARKS.

By JOHN G. FORBES, M.R.C.S., Surgeon to the Western General Dispensary.

The author introduced his case by some remarks on the difference of opinion which prevails regarding the propriety of attempting the removal of a foreign body, when impacted in a bronchial tube. The nature, size, and weight of the offending substance, and the age and previous state of health of the patient, he regards as important elements in the consideration of this question. The practicability of the operation is proved by the success which has attended its attempt in some instances, of which class those narrated by Mr. Liston are referred to. The difficulty of determining the exact position of the foreign body is an argument against the operation. If the diagnosis is clearly established—and there seems but small probability of the intruding substance being expectorated, on account of its nature and position—the author is of opinion that an early attempt should be made to extract it. The subject of the present case (Mrs. W——, aged 46) applied at the Western General Dispensary, on May 1, 1849, stating that on the previous day, whilst taking some broth, a small piece of solid matter, which she believed to be "bone, covered with gristle," passed into the windpipe. She was immediately seized with spasmodic cough and threatened suffocation, and it was some minutes before she recovered herself. Twenty-four hours after the accident her voice was hoarse; respiration slow and wheezing; there was a constant short cough and pain at the upper part of the chest. On the right side the natural vesicular murmur was scarcely audible, and a prolonged and peculiar rhonchus was heard throughout the lung, but most distinctly over the point to which the pain was referred. On the evening of the third day, the patient was affected with considerable constitutional disturbance, ushered in by a long shivering fit. On the fifth day, (May 14,) when the author visited his patient, he was accompanied by Dr. M'Intyre, Mr. Arnott, and Mr. Anderson. A remission of symptoms had suddenly taken place; and it was decided, that an operaton should not then be performed. On the 16th, the cooing sound had generated into a peculiar whiff or puff. The expectoration was more copious, and the cough troublesome, and aggravated by the slightest exertion or excitement. Mr. Arnott again saw the patient, in consultation with the author and his colleagues; but, as the symptoms of the patient were not very urgent, and it was very uncertain exactly where the foreign body was fixed, it was thought prudent not to operate. During the ensuing fortnight, the symptoms were, disturbed nights; paroxysms of fever; profuse night sweats, &c.; and the cough assumed a more paroxysmal character. On June 1st, the symptoms were further aggravated, the expectoration becoming more abundant. After this date, until June 21st, there was considerable amendment in the general condition of the patient; but, on the 22nd, the expectoration assumed a dingy appearance, and offensive odour; the breathing and pulse were hurried. On the 25th, the fetid, purulent expectoration was increased, and the constitutional disturbance further aggravated; and from this time she never rallied, but died on the 5th of July. *Autopsy.*—The carotid artery of the right side was observed to take an abnormal course, running obliquely upwards, and to the right side in front of the trachea. The right lung filled its own side of the chest, and in its inferior two-thirds, was adherent to the ribs and diaphragm; and close upon the latter, in front, there was a pleuritic abscess, the size of the palm of a hand. The foreign body, a small piece of bone, weighing when dry three grains and a half, partly rough and sharp, and in part smooth, was found firmly impacted in the orifice of the third branch, given off from the bronchus, which passed into the middle lobe; a circumstance which accounted for the fact which had been noticed during life, that air passed with comparative freedom into the upper part of the affected lung. The lower two-thirds of the same lung were of an ashy slate colour, of dense consistence; very offensive odour, and infiltrated with a purulent fluid. That part of the upper lobe which was supplied with air, appears healthy. The

author concluded by directing attention to the risk which would have been incurred, of wounding the right carotid artery, had an operation been attempted.

Dr. Black remarked that there were not any points in the paper which had just been read which specially called for discussion. There were, however, many excellent points in it, which were very correctly given. The symptoms of the case might be fairly divided into two distinct epochs—those in the first being indicative of the irritation caused by the presence of the foreign body; and in the second, of the inflammatory action, which was subsequently set up in the lungs. There was one symptom of considerable importance noticed in the first condition, which he was able to corroborate,—the expectoration consisted simply of frothy mucus. This he had always found to be the case when the irritation was caused by obstruction only. The natural secretion of the lining membrane of the lungs in an uninflamed state, continued to be poured forth under such circumstances, but frequently so increased in amount as to fill several vessels—the usual spitting vessels found in hospitals—in a short time. If in any case there existed a doubt as to the presence of a foreign body in the lungs, causing obstruction of the air tubes, this character of the expectoration would be useful in forming the diagnosis. When the dyspnœa is referrible to obstruction only, the secretion is the same as from an uninflamed surface; but in bronchitis, with dyspnœa and cough, the secretion is poured forth from an inflamed surface, and is changed in character. These diagnostic indications were of service as a guide to the necessity for an operation, and their neglect, as he had noticed, might lead to bad results.

Dr. Addison inquired if the contents of the abscess were offensive?

Mr. Gregory Forbes having answered in the affirmative,

Dr. Addison added, that he had inquired, because the appearance of the lung was very much like that of a lung into which an abscess containing offensive matter had made its way.

Dr. Sibson said, that if a foreign body fell into either bronchus, it would be into the right, its direction being comparatively straight. It would also of necessity not fall into the upper branches of the bronchus, but would pass them, and fall into the lowest, as it had done in the case before the Society. The ground is thus far narrowed. A loss of expansion during respiration, and a falling in over the part where the foreign body is, with the aid of the other auscultatory and physical signs, will indicate its position,—a knowledge of which should be accurately obtained before any operation for the removal of the extraneous substance is made. With this object in view, it is requisite to be well acquainted with the position of the bifurcation of the trachea, and of the larger bronchi, relative to the spine. He (Dr. Sibson) had examined about eight bodies from behind forwards, and had found that the division of the trachea was just in front of the fifth or sixth dorsal vertebra, and the lower branch of the right bronchus about an inch lower down, or nearly opposite the seventh or eighth dorsal vertebra. During inspiration, on account of the descent of the diaphragm, the bifurcation of the trachea is drawn downwards, and during expiration it is rather higher than the part just mentioned. In Mr. Forbes' case, the process of respiration was obstructed in the lowest lobe, owing to the presence of the foreign body, while the upper ones were free. Expiration can be carried on readily when a bronchial tube, or the larynx, is obstructed by a foreign body, while respiration is impeded, it being easier for the air in the lungs to escape during respiration from behind the foreign body, than for air to enter the lung in opposition to the foreign body, which, in all probability, would be impelled further into the tube by the entering air. The consequence of this is, that all the air in the obstructed portion of lung is expelled, and then follows a falling in of the chest over that part, constituting an important point of evidence as to the seat of the foreign body. This falling in of the chest, with the want of motion in its parietes, and the definite sign of dulness on percussion, are all contrasted with the reverse condition, which exists, even in an exaggerated state, in the unaffected lung, and sometimes even in those portions of the affected lung which are not involved in the obstruction. An interesting point in Mr. Forbes' case referred to the measurement of the respective sides of the chest; it was stated that, in that case, both were equal; now he had found, on measuring several chests, that the right was half an inch larger than the left; it was probable, therefore, that the right side of the chest, in the case under notice, had lost that half inch. There was generally great difficulty experienced in extracting these foreign bodies. It had occurred to him that an instrument, similar to Dr. Simpson's air tractor, might be useful in their extraction. With respect to the peculiar position of the carotid artery, in crossing over the lower part of the trachea, he (Dr. Sibson) did not look upon it as abnormal. He had met with it in many cases where the chest was very small, but when the lungs are fully distended, this vessel and the innominata are drawn down within the chest, the sternum the while ascending and concealing, or, rather, covering the arteries at that part.

Dr. C. J. B. Williams said, that the case they had just heard read was a very instructive one, as illustrating the diagnosis and pathology of foreign bodies in the air-tube. He would wish to make one or two remarks respecting the diagnosis. The foreign body in this case was of so small a size and so peculiar a figure, that it was not adapted to show many physical signs of its presence, and yet, as its history proved, it did produce some very peculiar indications thereof. He thought there were very few cases in which, by careful management, and an accurate examination of the respiration, and of the difference therein from position, some physical signs of the presence of a foreign body would not be elicited. A difference in the shape of the foreign body would cause a difference in the physical signs indicative of its presence. Angular bodies, for instance, would not give rise to signs of total obstruction. In the case before the Society, the greater number of pathological symptoms depended on irritation, and not on complete obstruction. The latter condition would be caused by rounded bodies, which were able to plug up a bronchial tube completely—as was shown by a case related during the last session, in which a pebble had got into one of the bronchi. When the foreign body is moveable, and does not quite plug up the tube, peculiar sounds would be heard, which would readily enable us to diagnose its presentation. A foreign body in the right bronchus would be more readily discovered by an examination of the back than of the front part of the chest, as the tube there is nearer the exterior. The pathological changes which are induced by the presence of a foreign body illustrate its influence on the textures: signs of irritation are first induced, subsequently more or less pain, and cough of a spasmodic character, and dyspnœa, evidently also produced by spasm. It is remarkable, how long some foreign bodies may remain in the air-tubes without causing irritation at all. Smooth bodies are not calculated to induce inflammatory action; but they do so ultimately. The inflammation thus caused does not resemble ordinary bronchitis, but passes into the chronic stage. It is characterised by bloody expectoration, which soon becomes putrefactive and offensive. Liston often diagnosed the presence of foreign bodies in the air-tubes by the odour of the expectoration. In a case in which he had done so, a portion of the cricoid cartilage, which had become ossified, had separated, and fallen down into the bronchus, where it had produced all the symptoms indicative of the presence of a foreign body. The existence of such a cause of irritation was not at the time suspected. Liston, however, operated for tracheotomy, and after a time the ossified cartilage was expelled through the opening, during a fit of convulsive coughing. After death another piece of ossified cartilage was found in the left bronchus, having been separated and fallen down subsequently to the performance of the operation. The pathological changes in this case were the same as are usually met with; these were—fetid breath, purulent expectoration, &c., and the lung was found in a consolidated state. The patient appeared to die of a low form of suppurative pneumonia. He thought, from this and other cases, that it was necessary and advisable to remove the foreign body as soon as possible after the accident had occurred. It should be performed early, before the accident had affected the lungs, before bronchitis had been set up, or congestion of the organ had occurred; if not, the admission of air through the opening might be followed by injurious consequences. Had the operation, in the case before the Society, been practised before inflammatory action was set up, the patient might have recovered.

Mr. Arnott, in reply, observed that Dr. Williams had stated that, if the operation had been performed early in this case, the foreign body might have been removed, and the patient would probably have recovered. He had seen the case five or six days after the accident was reported to have occurred; he was told that the woman had swallowed a piece of bone or gristle—it was doubtful which. There had been symptoms indicative of the presence of a foreign body; but when he saw the case, there was a lull in the symptoms. The first question to be decided was—whether there were a foreign body in the bronchus or not; and the second, whether it were moveable; because then, if an opening in the trachea were made, it might be expelled through it during a paroxysm of convulsive coughing, or if there were no such paroxysm, it might be extracted. The woman had suffered from pain in the chest previously. There was not any evidence as to where it lay; the upper part of the chest was clear on percussion, and consequently it was not in the bronchus leading to the upper lobe; it might certainly be in a branch of the bronchus; but what physician could place his finger on the exact spot where it lay? In the absence, therefore, of any clear evidence as to the absolute position of this foreign body, he did not think that any surgeon would be justified in operating. The question, under such circumstances, should be—is there a fair chance of succeeding? With the knowledge they have now, from the *post mortem* examination of this case, if a similar one were to occur, he should certainly operate, but still it would be without any certainty of success. In this case the foreign body lay in the third or lowest branch of the right bronchus, and was firmly grasped by the tube, which it entirely filled; and, consequently, there would be great difficulty in passing and using the peculiar kind of forceps which is requisite for the removal of foreign bodies under such circumstances. The instrument might, perhaps, be used with safety in the first or the second branch of the bronchus, but scarcely so in the third. With regard to this particular case, seeing that the carotid artery ran across the lower part of the trachea, it in all probability would have been notched or wounded during the operation, and the patient might have died of hæmorrhage on the table. It taught us that great caution should be practised in all operations on that part of the neck, or near the upper part of the sternum.

Dr. Pettigrew considered the course the carotid artery took in this case to be exceedingly rare. He had never met with an example. With respect to the possibility of a piece of gristle in the air-tubes becoming softened and expectorated, he thought it would be dangerous to trust to it. He had found that a piece of cabbage and other analogous matters would not. He believed it was difficult to ascertain when any substance had passed into the trachea; the physician must aid us in our diagnosis. It was not impossible, he thought, that Avery's speculum might be of use in such cases (?).

Mr. Holmes Coote considered the operation of introducing a large pair of forceps into the bronchi as not unattended with danger. He had seen two cases in which foreign bodies in the trachea had been coughed up, and expelled without operation. The patients recovered.

After some observations from Mr. Curling respecting the operation, the meeting was adjourned.

WESTMINSTER MEDICAL SOCIETY.
Nov. 10, 1849.

JOHN SNOW, M.D., in the Chair.

Mr. Canton described a case of enlarged lymphatic glands and diseased parotid, which he had recently extirpated. The patient had been under his care at the Royal Westminster Ophthalmic Hospital for amaurosis. It had been difficult to ascertain whether the last-named disease was functional or structural, but the result showed that it was organic, it not being amenable to treatment. After some time the patient complained of a swelling at the angle of the jaw, where there was found a slight elevation, about half an inch above the surface. The tumour was small and round, not easily movable, and apparently connected with the parotid. There was at that time little or no inconvenience from it, excepting some difficulty in opening or shutting the mouth, which increased as the tumour became larger. Iodine and mercurial plasters were used, and leeches applied occasionally, but without advantage. After a time the patient became deaf in the corresponding ear, the deafness increasing as the swelling became larger. It then became a question as to the propriety of operating, the depth to which the tumour extended not being ascertainable; its extent externally being from the mastoid process to the angle of the jaw. The reason that finally determined the operation was, that the man was already blind, and thus deprived of one essential comfort, and was becoming deaf of one ear—if at a future time the other ear lost its power, his life would be very miserable. The operation was accordingly performed, when the tumour was found to be composed of lymphatic, conglobate glands in the parotid: part of the latter gland was also removed. The tumour presented something of the fungoid character; it was not merely a simple enlargement. No ill resulted from the operation. Very little blood was lost, and the patient recovered without salivary fistula or paralysis. During the operation, however, the external jugular, which had been somewhat displaced by the growth of the tumour, was wounded; this might have been attended with danger, but Mr. Canton being aided by very efficient assistants, the finger was placed at once on the opening, and the vein secured. Some tenderness existed for a few days afterwards in the course of the vein, which was removed by leeches, fomentations, and salines. The patient recovered his hearing, and he thought for a time that his sight had improved; but this was not really the case.

Mr. Chippendale considered the case to be of importance, as illustrative of operations on the parotid. Anatomists generally considered that that gland could not be extirpated, and he believed that in the majority of cases where its extirpation had been announced, it was, as in this case, merely the lymphatic glands in the gland itself which had been removed.

Mr. Walton inquired if any microscopic examination of the tumour had been made?

Mr. Canton replied in the negative.

Mr. Walton then read the following case, which our woodcut well illustrates:—

James Clarke, aged 56, called on me in August of this year, and requested me to remove a tumour which was on the right side of his face and neck. I will briefly mention its physical characters. It was irregularly lobulated, and measured six inches in its transverse, a little more in its vertical diameter, seventeen inches around its base; and its thickness, that is, taking the parotid gland as its internal limit, to its most prominent external part, five inches and a half.

The general surface was hard; some few of the lobes, however, were elastic, and conveyed to the touch the sensation of fluctuation.

The highest portion was on a line with the zygoma; the lowest nearly reached the clavicle; the most posterior projected a little behind the mastoid process. The lower part of the ear was pushed upwards, and its lobe stretched out on the tumour. Its investing skin was healthy in every part, and inadherent.

The cast exhibited gave an accurate view of its size and boundaries.

The history was difficult to be obtained. The nearest approximation to the truth appears to be,

that seven years ago a "pimple" came under the ear; it increased, and, in twelve months, a second "pimple," similar to the first, appeared a little in front. They grew in proportion to their duration, and when the larger was about as big as a billiard-ball, seemed to coalesce. It was not until after their individuality was thus lost that lobes were detected. Within the last two years, the enlargement, as compared with the antecedent growth, has been disproportionately rapid. He says, that the easiest position in bed is to lie on the tumour. The functions of mastication, deglutition, and respiration, are not interfered with. The poor fellow had been a recluse for some years; he had not courage to stand the gaze of the curious, nor to hear the remarks of the inconsiderate, nor determination enough to resign himself to the surgeon. Now, however, feeling his condition of existence that of unendurable misery, he applied to me. I considered an operation practicable, and my opinion received confirmation from Messrs. Coulson and Shute, whose advice I sought. Dr. Routh, my colleague, kindly examined, with care, the thoracic and abdominal viscera, and reported, that so far as he could discover, there was exemption from organic disease. It was necessary for an accurate inspection to be made, because some circumstances induced me to suspect unhealthiness in the chest. Besides, chloroform was to be given, and, in all probability, a long employment of it would be necessary.

I shall now describe the operation, which was done on Sept. 2. The integuments were divided by three long cuts, two of which were nearly vertical, the one being along the posterior border of the tumour, the other along its anterior, and one transverse across the centre. The lower flap was reflected first, then the upper, and the final separation of the tumour completed from above to below.

Every part was taken away. A very dense cellular sheath enveloped it; the cervical portion was covered by the platysma muscle. The blood-vessels that supplied it, though numerous, were not large; to seven arteries were ligatures applied.

Here is the morbid mass; I have divided it. It weighed two pounds and three quarters. In the centre is a cavity, which was filled with a straw-coloured fluid. I should say that it is a good specimen of what Mr. Abernethy denominated pancreatic sarcoma, the non-malignant scirrhus of Dr. Warren. Dr. Routh, who examined it microscopically, says—"I find it to be in the main cartilage, with a few fibres. I saw one caudate corpuscle, but only one. This might have been some ill-shaped blood-globule. The liquid in the cavity of the tumour was serum and blood, with a few epithelium scales." Dr. Peacock, who also looked at it for me, confirmed Dr Routh's observations. He pronounced it to be a simple fibro-cartilaginous tumour, consisting of a delicate stroma, enclosing a small proportion of large nucleated cells. Of its pathology, I am more willing to receive than to give an opinion.

Report.—This may be very short. Recovery was rapid; on the third day the sutures were removed; on the 14th he returned home, the wound having quite healed, except at the angles of the upper flap, which were not as nicely put together as they should have been.

Remarks.—Here is well illustrated the fact, that a tumour, however large, matters not, surgically speaking, even when situated over the most intricate anatomical relations, so long as it is *free*, *i.e.*, does not form connexions by adhering to, passing amongst, or enveloping the important structures it covers. Mobility, the test by which we judge of the isolation, or the extent of a tumour, and decide whether an operation may be undertaken for its removal, is not an entire one; it is not capable of giving us the whole truth, yet, in proportion to its degree, are we enabled to pronounce with the greater certainty of the state of things.

Two instructive cases of tumours in the neck occurred, not long since in the practice of two eminent London surgeons. The tumours, not large, possessed so much freedom of motion, and seemed in every other respect so eligible for operation, that their extirpation was undertaken with the greatest confidence of easy execution. The one was abandoned because of its deep and intricate connexions, the outer portion that was freed, having been cut off. The other was got away entire, but its accomplishment required a very lengthy, and most difficult, and I may add, very dangerous dissection. Mr. Lawrence used to mention a case in his lectures, (and it seems to have made a deep impression, for I have heard him tell it on other occasions,) of a gentleman who came to him with a tumour about the size of an orange, partly behind and partly on the ramus of the jaw; it was moveable, yet on account of not being able to feel the whole of it, he was uncertain of its attachments. He advised an operation, but spoke of it as a formidable affair. Assent was given; the base, at which enormous arteries entered, was so deep that he could not get under it without cutting into the tumour; then he

found it necessary to slice off a portion to permit all, as he thought, to be removed, and which was apparently done, yet more was found, which, after tedious dissection, he traced between the external and internal carotid arteries to the front of the cervical vertebræ, and with his finger broke down the attachments. On the other hand, I must observe, that immobility is but an equivocal proof of complication, for a non-adherent tumour may be sufficiently bound down by fascia to prevent any motion: and if there were, as in all probability there would be in such a case, indefiniteness of outline, it would indeed be very difficult to decide whether an operation should be undertaken. A second cast was exhibited in which these circumstances were present, and in addition there was a pulsation communicated from the carotid artery, which much increased the obscurity. Surgical interference had been refused by those to whom the patient applied; it was thought that the carotid passed through it, and I undertook the operation because, from the history, I suspected the tumour to be free, but merely tied down by fascia, but especially, because both respiration and deglutition were interfered with, and became more impaired from week to week. The accession of such dangerous symptoms showing that the passages to the lungs and the stomach were narrowed, were very significant, and from them one of two important conclusions was to be drawn. They demonstrated either the tightness with which the tumour was bound, and hence perhaps the only cause of its immobility, or pointed out its extended, and may be, intricate connexions. I considered the former the proper interpretation; fortunately I was correct. I removed every part without dividing or injuring any of the important textures in the vicinity, except the portio dura, although many of them were necessarily exposed. The patient made a good recovery.

Such cases are very obscure, and all the evidence we can collect will not, on many occasions, allow us to speak but conjecturally. Tumours that appear to be incorporated with the surrounding textures (I exclude from consideration the malignant class) require a most careful consideration before deciding on an operation, for implication without is a pretty sure proof of a similar state within. An instructive case has been recorded in the fortieth volume of the *Medical Gazette*, by Mr. Henry Smith, of a fibrous tumour of the neck that was sent to London by a surgeon for operation. The gentleman to whom it was consigned declined interference; its external limits seemed to him too much blended with the healthy structures to warrant the use of the knife. The patient died. After describing its extensive and varied connexions, Mr. Smith says—"The arteria innominata entered at its lower border, and then immediately divided into its two branches; the carotid artery passed through its substance, and the trachea and œsophagus were closely adherent to it."

Another cast shown by Mr. Walton exhibited the external characters of those small, hard, and tight tumours that are occasionally met with in the situation of the parotid gland, and which, causing the greater part of that gland to disappear, send in prolongations, and wedge themselves in the long channels between the mastoid and styloid processes, and between the latter process and the jaw, and become immovable. Although there is here to the eye an indistinctness of limit, the finger can trace satisfactorily a disconnexion between its outer portion and the neighbouring parts. It has existed for more than a year, and is on the increase. Here our valuable guide for the propriety of operation does not avail us. Insusceptibility of motion must not be taken into account if other circumstances do not forbid an operation.

It is in the large growths with wide bases, of which the subject of my paper is an excellent example, that our foreknowledge of connexion and extent is the less sure, because their circumference prevents the outline of the parts on which they lie being traced, and their mere size may to some extent overcome the tension and firmness of adhesions, or of prolongations, and deceive us; for, handle them as you will, they must carry weight with them. The source and extent of the vascular supply of cervical tumours must always be a matter of uncertainty. Their size does not afford any criterion. There can be but few present, if indeed there are any, who require to be told, that sometimes after tying all the vessels on which ligatures can be placed, and resorting to every other means for stopping hæmorrhage, including tying the common carotid artery, the patient may sink from loss of blood. All the foregoing circumstances show the necessity of thoroughly studying tumours surgically, and being ever prepared for emergencies.

The H like manner of dividing the integuments was adopted because it would produce less after deformity than any other, is the best adapted for the removal of large tumours, and by it the flaps were most advantageously arranged; for here, and, indeed, in other operations where extensive dissection of skin is required, it is better if a choice can be commanded, to make the flaps in a line with you, or above and below, according to the position of the patient, rather than laterally, because they may then be reflected with more ease and facility, and the crossing of hands, or the change of position of the operator, or of his assistant, is avoided,—an awkwardness that must ensue if they are lateral, and the right hand alone employed with the knife.

The last point I shall notice, is that of taking away portions of skin at the time of extirpating large growths, under the idea that there will be more than can be required, or that it will, from its superfluity, be an impediment to favourable recovery. For a long time my impression has been, that it is injudicious to remove skin without also removing the part that it naturally covers, because, in all probability, its want will be felt during the healing process, or its loss more or less apparent subsequently, if not actually detrimental. Of course, much must depend on the amount removed, and the situation whence it is taken. I am well aware, that instances can be advanced of loss of skin without any demonstrable disadvantage. It is the broad rule, and not the exception, that I argue *for*; besides, if in freeing the body of disease, an equally good result can be obtained without the loss of a particular structure, it is our duty to preserve it. The high and daily increasing appreciation of conservative surgery supersedes the necessity of my saying more. I have met with several persons who consider that there is always an actual growth of skin commensurate with the tumour it covers, and advance that as a necessity for taking some of it away. I do not think that any proof has been afforded in evidence of the assertion; even if there were, their conclusion may be unsound; for, in all probability, by the same law that skin would be produced when wanted, it would, in time, be removed when useless.

When skin is diseased it should be removed; a course to be adopted when it is adherent, and cannot be entirely separated from what it covers without injuring its texture, or whenever it exhibits a decidedly unhealthy action, or when greatly attenuated, in which state I presume its physical properties to be almost entirely destroyed. These are rather beyond my present consideration. My remarks are meant to apply to healthy cuticular structure. If skin be merely stretched over a tumour, as well as pulled from the surrounding parts, on being liberated it will, in time, contract and recede, and so recover itself. Of course there will often be more or less traces of the injury it has received in the stretching. In the natural state of our bodies the skin is always exerting its elasticity, the exercise of which property is extended to the flabby coverings from adventitious growths, and in no inconsiderable manner adjusts them to their natural places 'till they regain their suspended functions. It is because this elasticity is not sufficiently recognised that we frequently see such shocking stumps after amputations, even in flap operations, arising from insufficient integument. The scalp which is harder and less elastic than the general skin affords a remarkable example of recovery after being stretched. From its dense cellular attachments, the covering of a tumour must be almost entirely provided by that portion corresponding to the spot at which the abnormal growth commences; and hence, the usual form of such tumours; for as the adjacent parts will not yield, and lend a covering, the skin is always thinned; yet I am in the habit of removing such tumours,—and some of them have been large,—without taking away a particle of the skin, and have always obtained good results. Some surgeons adopt a different course,—they take away every portion of skin; in fact, shave off the tumours, and then attempt to retain together the edges of the scalp by sutures and strapping. I speak from what I have seen. Surely, these submitted their patients to a tedious cure, together with a risk of erysipelas. I do not mean to attribute the latter to the sutures.

It is not immediately that a wound has healed after the extirpation of a tumour, that we can judge of the future condition of the parts. The lapse of months, or even a year may be required, before the stretched skin has recovered to its utmost. In the aged we must not expect, indeed we cannot have the same manifestation of physical properties of the skin that belong to early life, because it naturally becomes thin and less elastic and contractile, and here may be an exception to the rule I have ventured to lay down, and for which sufficient exception must be made. In the case under consideration I was induced, although with reluctance, to take off a portion of the lower flap; I submitted to the advice of a friend that assisted me. I am not astonished that I accepted his counsel, seeing that there was so much loose skin corresponding to so small an amount of under surface, a disproportion that I had never before witnessed. Had the operation been anywhere about the trunk, most decidedly I would not have removed any part of it; I thought there was a risk of its sloughing, the disadvantage of which would be greater in the neck and face than elsewhere. The course I adopted is the most convincing proof I can give you, that I do not state a proposition, and act up to it in every instance contrary to strong impression or conviction. Here, as in every rule of surgery, certain reservation must be allowed for the exercise of discretion and judgment, without which we shall be continually erring. I believe it was the impression of those present, that with the reduction I had made, considerably too much skin was left; but the rapid union that ensued, added to the present state of the parts, shows that such was not the case. I cannot say that I do not feel regret at not carrying out my original intentions, because I think that the case would have done well, and that I have lost an opportunity of example.

It should always be our endeavour to preserve to the skin all of its deeper layer, so that its elastic and contractile tissues may not be injured; and this will be best effected by making the incisions deep, at once reaching the surface of the tumour, a plan that also much facilitates the dissection. Without having made any observations on the subject, but judging merely from inference, I should expect the greatest restoration of distended skin in the instances of fatty tumours, where its texture is so little injured either by the abnormal growth or in the dissection, for the separation is easily effected—less, when it covers tumours surrounded with a cellular sheath, for then its circulation is, I think, generally more or less impaired—and least in the encysted tumours, over which it is for the most part thinned. In conclusion, I would say that I believe there need not be any fear as to the fate of large flaps, provided they have a proper vital supply, and are brought together sufficiently accurately, and supported by a soft compress. The swelling of them and of the subjacent parts soon effect an adaptation that will insure a successful issue.

Present state of the patient, Nov. 9.—There is yet swelling about the cheek; the upper flap has nearly lost the folds that formed in it after the operation. The lower flap is quite level. It is easily perceived, when viewing the neck, that a portion of skin has been lost. The slight amount of deformity that exists is almost incredible.

Mr. Travers, jun., had listened with great attention to Mr. Walton's paper, having operated on three

occasions on large tumours in this situation with success, and having seen the operation abandoned in other instances after it had been commenced. In one of these cases,—a large tumour connected with the occiput,—either a large branch of the occipital or the main trunk had been wounded; frightful hæmorrhage took place, sloughing followed, and the patient died. In another instance a ligature was applied on a tumour connected with the air tube. Laryngitis followed, and proved fatal in a few days. He thought that, in tumours connected with the neck and face, great allowance is to be made for fascial attachments. If the tumour stand out, be plainly moveable, and nothing covering the surface and sides but integuments, it was a case for operation; but if, on the contrary, it be lobulated, apparently subject to great pressure from fascia and run into crevices, it will take on a malignant character, and belongs to a class of tumours which surgery cannot get out. It was so in the two cases alluded to; the disease was fungoid, approaching to malignancy. In such cases the surgeon should endeavour to satisfy himself whether the tumour presented the malignant character; if it did not, the chances were it might be removed with success. Tumours in the vicinity of the jaw may appear superficial, yet when the operation is performed, the surgeon may have to go to a very great depth. In one instance this was done to such an extent, as to expose the deeply-seated parts. He would not say the parotid had been removed, but he believed that portions of that gland had been taken away in some instances. The objections to the operation for extirpation of the parotid are anatomically correct, but changes may be produced by disease, so as to admit of its removal. In operating for the removal of tumours in this situation, we must be prepared for hæmorrhage, when we go to any depth; it is generally pretty active, and of a nasty description—a welling bleeding from the bottom of a deep wound—the blood issuing from a small branch shaved off so closely, as not to hold a ligature, which may be applied repeatedly, but ineffectually. In such cases he (Mr. B. Travers, jun.) had known dressers obliged to sit up night and day for many days together, exerting pressure on the bleeding parts until the hæmorrhage was suppressed. Hæmorrhage, however, is not an occurrence to arrest a surgeon, who is acquainted with the anatomy of the parts. In two cases in which he had operated, paralysis had occurred—that is to say, ptosis, or rather an inability to close the eyelids, the angle of the mouth drawn down, and the ala of the nose collapsed. In one of the cases there was troublesome epiphora. In both instances the patients were comparatively well at the end of eighteen months or two years. There was not any inconvenience after that time. The epiphora also subsided. With respect to the removal of skin, he agreed in opinion with Mr. Walton; and always looked with a feeling of apprehension with reference to the subsequent healing, when the dissecting up of flaps was practised. Thin-skinned flaps in amputations were bad for the skin and the parts below; the process of healing went on very slowly, and there was great risk of erysipelas. In merely pedunculate tumours, it was proper to remove them with a single swoop of the knife. He had done this with a fatty tumour on the inside of the thigh, and with another tumour, also pedunculate, which hung from the margin of the anus. In both cases he removed the integuments along with the diseased growth. Mr. B. Travers then referred to the operation on Hoo Loo, which was performed some years since by the late Mr. Key. He considered the disease in that case to have been strictly a pedunculate tumour; the parts had, by its weight, been drawn down into a round stalk-like process. The operation was begun with the intention to save the cords and testes; the hæmorrhage which followed the division of large veins, on the second or third incision, caused the feeble Asiatic, if not to die on the operating table, at least, very soon afterwards. In such a case, he thought it would be better to remove all the diseased parts by a single swoop of the knife, and control the frightful hæmorrhage that would follow by means of the actual cautery. If the skin be removed in an operation, there being a large surface left, the process of healing is carried on very slowly, and there is a great additional call upon the patient's strength. This it is very desirable to avoid. He fully agreed with Mr. Walton, except as regards the removal of pedunculate tumours.

Mr. Chippendale explained, that when he spoke of the non-removal of the parotid, he did not mean to imply that portions of it could not be cut away, but that the entire gland could not be extirpated. Mr. B. Travers thought that the alterations of disease might enable it to be removed; but, in his opinion, if there were extensive disease of the gland, there would be greater difficulty in extirpating it. He saw, nine years ago, a case of medullary sarcoma of the upper part of the thigh, in which the femoral artery was involved; the tumour was neatly dissected out, and the artery exposed for about two inches in extent. No evil resulted; the part healed kindly, but the disease returned, and the patient died. In another case, which was under the care of the late Sir Charles Bell—a pedunculate tumour of the inside of the knee; it was removed, not by a single sweep of the knife, but by two small semi-elliptical incisions. Sloughing followed, and the patient died. He (Mr. Chippendale) quite concurred in the necessity for the preservation of the skin. It should be remembered that there was not an additional growth of integument, when a tumour formed beneath it, but merely a stretching of that already existing.

Dr. Daniell referred to a case where there was an apparently hard and solid tumour under the angle of the jaw. It was removed by a very careful and neat dissection, and then was found merely to contain a fluid. Had the exploring needle been used in this case, the danger of the operation might have been avoided.

Mr. Canton remarked, that there were other tumours of the neck besides those described by Mr. Walton, which presented features of great interest to the operating surgeon, *e. g.*, those formed in the substance of the thyroid gland, and even the enlargement of that body itself. The different varieties of these growths were mentioned, and the operation most likely to be beneficial in each pointed out. With respect to goitre, Mr. Canton believed, that when symptoms of cerebral congestion arose, owing to the impediment caused by a large bronchocele to the free return of blood from the head, together with difficulty in deglutition and respiration from pressure on the œsophagus and trachea, that the plan of making a subcutaneous section of the sterno-hyoid and thyroid muscles might advantageously be had recourse to; inasmuch as they materially retarded the forward growth of the tumour, and were, in such cases, found to have their fibres separated, so that as broad ribbons, they bound down the swelling at its forepart and sides, and thus induced the functional disturbances alluded to. The operation of tying the thyroid arteries was next spoken of. With reference to the tumour of the parotid gland Mr. Canton had brought forward, he believed that it was in such instances that extirpation of the *secreting* gland was supposed to have been performed; for, the lymphatic growth in its progress having produced absorption of the part in which it was embedded, the error might readily be fallen into by those who believed in the practicability of the total removal of the parotid.

Mr. Walton quite agreed with Mr. B. Travers that pedunculate tumours constituted an exception to the non-removal of skin. It was an omission on his part not to have made that exception. In Hoo Loo's case, the disease was elephantiasis, and the case came under the head of diseased skin. In reply to Mr. Canton, he would say he had intentionally avoided going into the subject of tumours of the neck generally, as it would have occupied too much time.

THE PERIODOSCOPE.

Dr. Tyler Smith exhibited two periodoscopes, one made in ivory, and the other in metal. He observed that the periods between different labours were multiples of twenty-eight days, or of the ovarian periods. Again, in cases of superfœtation, when one child was born at the full period, and the other not until two, three, four, or five months afterwards, the second parturition had a tendency to obey the same law. The periodoscope would, therefore, be useful to trace these; the ovarian period was twenty-eight days; when we got the date of the conception, by referring to the instrument, and taking ten periods after that date, we should have the date of parturition. When there is a tendency to abortion, it generally occurs at the catamenial periods; the periodoscope will teach us when that date occurs, when consequently more than ordinary care should be practised. He thought the cause of labour was an ovarian excitement at the tenth period, producing an excitement of the ovarian and uterine apparatus, which terminated in labour. The only objection to this opinion was that which considered parturition to be induced by the mature state of the fœtus. This latter opinion, however, was not borne out.

Some discussion took place afterwards, with reference to the appearance of the catamenia during pregnancy, which was supposed to depend on a congested and ulcerated state of the cervix and os uteri, the usual white discharge being changed to blood by the occurrence of the excitement attending the ovarian periods.

The meeting then adjourned.

MEDICAL SOCIETY OF LONDON.

Nov. 12, 1849.

HENRY HANCOCK, Esq., in the Chair.

CHOLERA.

Dr. Clutterbuck referred to a case of cholera which he considered important, not as showing the power of Homœopathy, by which it was treated, but its negative good qualities. He had come to the conclusion, that the employment of very active medicaments in cholera added to the danger; and that more persons were destroyed by the treatment than were saved—if any were—which he very much doubted. He condemned large doses of calomel and opium.

Dr. Crisp differed in opinion with Dr. Clutterbuck. He could not assent to Dr. Clutterbuck's opinion as to the inefficiency of medicine in the treatment of cholera, which, when taken in its early stage, was manageable.

Mr. Robarts confirmed Dr. Crisp's statement, that there was not any disease so amenable to treatment as cholera, excepting in those cases where the patients were all but dead when application was made for professional assistance.

Dr. Toogood Downing then read an interesting paper on,

THE PROXIMATE CAUSE AND TREATMENT OF EPIDEMIC CHOLERA.

Without offering an opinion on the mysterious exciting cause of the malady, Dr. Downing said, that a close observation of its history and phenomena had convinced him, that whatever its nature might be, it produces spasm of the vital organs, and that cholera should be regarded and treated as a spasmodic affection; not merely of the external voluntary muscles, but of the internal, involuntary, and vital also. He was aware that it had often been styled spasmodic cholera; this was merely on account of the external spasms, but the probability of a similar state coexisting in the internal organs had been either overlooked or disregarded. The reasons on which his opinion was founded were, 1st. The premonitory symptoms indicate spasm of the vital organs. He did not allude to the diarrhœa or sickness, but to a class of sensations due to the influence of the surrounding poison. These more resembled the effects of fear than anything else, and were frequently erroneously attributed to panic. The apparent terror is the first effect of the poison. Healthy people, not thinking of cholera, suddenly seized with violent tremors, the surface of the body was in a moment covered with profuse perspiration, and then alternating with burning heat. A sensation of sinking within, of emptiness, and sudden prostration of strength. These feelings were also preceded, accompanied, or followed by more unequivocal indications of muscular tension, such as spasms, croup, and colic. These symptoms Dr. Downing considered were all referrible to internal spasm. 2nd. The mode of seizure, which is usually *sudden*. However long the premonitory symptoms, or the preceding diarrhœa

the attack of cholera, properly so called, is instantaneous. In tropical climates, and occasionally here, there are no premonitory symptoms. The patient is struck by cholera as if by lightning. Re-action is also as sudden as the seizure. 3rd. The features of the attack are spasmodic. The action of the stomach is a cramp. Spasm in the bowels is shown by pain, evident contraction, and the force with which the evacuations are ejected. Spasm attacking the biliary and cystic ducts, causes a perfect retention of bile. The flow of this fluid, that is, the cessation of spasm, is one of the best and earliest indications of recovery. The varying nature of the symptoms is due to the fitful character of spasm. In the stage of collapse, Dr. Downing believes, that not only are the heart and great vessels spasmodically affected, but the arteries throughout the body and limbs are equally diminished in calibre. In this way the blood gorges the veins, and its watery particles are forced into the intestines to supply the rice-water evacuations, or appear upon the surface as cold clammy perspiration. Death occurs chiefly by an exhaustion of the nervous energy. The external cramps in the back and limbs are not essential to the disease, but mark its severity and true nature. 4th. No morbid appearance is sufficiently *constant*, upon dissection, to lead to the conclusion that on it depended the phenomena. If cholera be a spasm, there is no necessary organic change. The derangement is functional,—spasmodic,—and therefore leaves no trace of its existence after death. This view is strengthened by the fact, that the morbid appearances are slight in proportion to the rapidity and severity of the disease. That is, the more sudden and awful the visitation, the fewer traces of its ravages remain. 5th. The extreme irritability of the muscular fibre after death. 6th. The observed effect of the more active remedies, such as bloodletting, opium, stimulants, chloroform. We employ such in other spasmodic affections. 7th. Dr. Downing remarked, that the very same arguments employed to prove true asthma a spasmodic affection, could be applied to cholera. These are—the sensation of constriction or cramp in the chest; the co-existence of spasms in in the calves of the legs; the rapidity of the accession, and suddenness of the cessation of dyspnœa; the affection being suddenly produced by certain causes of irritation, and even by mental impressions—suddenly relieved sometimes by medicines which we reckoned antispasmodic, and the absence of organic change on dissection. Lastly, Dr. Downing considered that if this view of the subject be correct, a clue is afforded to certain hitherto obscure points in the history of cholera. Its origin in the swampy Delta of the Ganges; its progress along banks of rivers and inlets of the sea, and its devastation among a squalid, ill-fed, and crowded population. In fact, it would obey the same laws, and be promoted and retarded in the same manner as other spasmodic affections. Respecting the treatment, the author considered that the indications were, to allay the morbid excitement of the nervous system, and to release the vital organs from the thraldom of spasmodic oppression. He did not advocate any one specific remedy for this complaint, but suggested that a more extensive trial should be made of hydrocyanic acid, as he had observed the best effects follow its use in certain cases. He had administered Scheele's acid in doses of two or three drops every hour or half-hour in extreme collapse, with manifest advantage. Mr. Shea, of the Blackfriars-road, had tried the remedy at Dr. Downing's suggestion, in more than one hundred cases of cholera during the recent epidemic, and, in a letter which was read, stated his conviction that it was superior to anything he had ever before employed. He had given it to children as young as nine months old, with excellent effect, and he had never in any case found prejudicial effects follow its use.

Mr. Clarke inquired, in how many cases of cholera Dr. Downing had employed prussic acid, and how long would he persist in its exhibition, if it failed to induce re-action?

Dr. Downing replied, that not being attached to any public Institution, his opportunities for treating the disease were not extensive. He had, however, seen many of Mr. Shea's cases, besides others in private practice, and at dispensaries. His own cases had not exceeded between thirty and forty; in only one case was there no re-action, and in that the patient died. She was in the very worst stage of collapse when he was called in; he prescribed for her, and when he returned in two hours she was dead. The friends said, that after the medicine had been given, a remarkable change had occurred: evident indications of re-action were discovered, but collapse recurred, and the prussic acid ultimately failed to rouse the vital energies.

[We regret that want of space prevents us from reporting the discussion that followed.—Ed.]

CORRESPONDENCE.

CORONERS' INQUESTS.

[To the Editor of the Medical Times.]

Sir,—In your leading article of the 27th ult., relative to Coroners and medical witnesses, the concluding sentence runs:—"The claimant, however, can recover by obtaining a *mandamus* against the Coroner." Let me ask if, having been nonsuited in the County Court through the "mala fides" of a Deputy Coroner, a claimant is precluded from proceeding in a superior court. It would appear, that, through a *misplaced reliance upon a public assurance*, an error was committed in the cause Lord *v.* Wakley, by proceeding in the County Court upon an informal plaint but does the informality of such proceeding, and, in consequence, the necessarily adverse decision of the Judge there presiding, bar the "claimant" from seeking the adjudication of a superior Court on the abstract merits of the case, through a *mandamus* The opinion and advice of His Honour, Mr. Heath on Mr. Synnot summoning Mr. Mills would appear to give a negative answer.

A reply from you to this point may be interesting to other members of the Profession, even more than to myself, who, I find, are resolving, day by day, no longer to regard the gibes, nor to take for gospel the decrees of the *Lancet*.

I have the honour to be, Sir,
Your obedient and respectful servant,
Charles F. J. Lord.

Hampstead, Nov. 12th, 1849.

[The issue of the two cases referred to by our Correspondent,—viz., the case of Synnot *v.* Mills and Lord *v.* Wakley, show clearly enough that a medical practitioner cannot recover his fee from the Coroner through the agency of the County Court, unless he has received a *legal summons* from the latter; the County Court being, as we have already said, a court for the settlement of what may be termed contract claims. If, therefore, any contract or legal agreement between the disputants is not clearly established, the case must necessarily fall to the ground, and the claimant be nonsuited. But this circumstance cannot in any way prevent the suitor from seeking redress through the agency of a superior court. He can, for instance, appeal to the Court of Queen's Bench, which, acting upon the merits of the case, would grant a writ of *mandamus* ordering the Coroner to do justice, according to the powers of his office.

We refrain from making any comment on Mr Lord's case; but this we will say, that if Mr. Wakley considered Mr. Lord to be a contumacious witness, he might and ought to have committed him for contempt; failing, however, to do this, the Coroner can show no legal reason or cause why he should not remunerate the witness for his attendance at the inquest, according to the terms of the statute."—Ed. *Med. Times.*]

[To the Editor of the Medical Times.]

Sir,—May I beg the favour of your advice under the following circumstances:—

It repeatedly occurs that inquests are held in this neighbourhood, where there is not the slightest necessity for an inquiry, and the farce is gone through, apparently for the sole purpose of providing the Coroner and the constable with their fees. Now, under these circumstances, it is policy on the part of the Coroner to avoid swelling his account by extra fees, and, as a natural consequence, he nearly invariably dispenses with the evidence of a surgeon; so that, in cases where the evidence of the surgeon who has been called in to the case is absolutely necessary to ascertain the exact cause of death, the usual verdicts, "Accidental death," or "Died by the Visitation of God," are adopted. The following case will relate, and shall be glad to know if any steps can be taken to prevent such an unjust proceeding for the future.

On Monday, the 12th inst., a farmer left his house on horseback about five o'clock, p.m., to transact business at a village about half a mile distant. His habits were exceedingly intemperate, and he was in a state of intoxication when he started, between ten and eleven o'clock, for his home. A neighbour, with whom he had been drinking, accompanied him until he reached his own farm, and then left him. Between four and five o'clock on the following morning, the servants discovered their master lying within a few steps of his kitchen-door in a state of insensibility, and his horse grazing in a neighbouring field; they removed the poor fellow into the house, and laid him upon a sofa, hoping he wound soon "come round!" but, after the lapse of a few hours, finding they could not get him to speak they became alarmed and sent for his surgeon, who attended him until Wednesday evening, when the man died, never having shown the slightest consciousness from the time he was found. There was a contused wound over the left temple, and the left eye was swollen and discoloured. An inquest was held, and a verdict found without the evidence of a surgeon.

I am, Sir, your obedient servant,
Thos. Godfrey, M.R.C.S.L., &c.

[From the facts given by our Correspondent, it appears clear to us, that the evidence of a Medical man ought to have been taken in the case referred to. If such proceedings as he details are of frequent occurrence, we should advise him to obtain carefully, accurately, and minutely the particulars, and lay the whole before the magistrates for the county. If that has no effect, transmit the particulars to the Secretary of State for the Home Department.—Ed. *Med. Times.*]

POOR-LAW MEDICAL REFORM.

[To the Editor of the Medical Times.]

Sir,—Although there has been little said in your Journal lately respecting the movements of the Poor-law Medical Officers, in the endeavour to obtain some redress of their grievances, I trust that their efforts have not slackened, but that all are busily employed in obtaining signatures to petitions, each in his respective locality, for presentation to Parliament, by the town or county members. I would suggest, that each secretary of a district, or other medical officer, should either have a personal interview with his representatives in Parliament, or correspond by letter, placing the subject in its true light, so that none may be able to plead that he is unacquainted with the wrongs of those medical gentlemen who are in office under the Poor-law. There is no doubt, but that by obtaining signatures to petitions in every town and neighbourhood throughout the kingdom, we should be able to succeed in procuring, if not sufficient, yet a better remuneration for our services than the Guardians at present allow. If each member of the staff will assist, we shall be victorious; and for the honour and dignity of the Profession, it is to be hoped that no one will withdraw his cordial co-operation with his brethren. It is to be remembered, that if the votes of medical men were withheld from those candidates for Parliamentary seats, who will not give a fair attention to the demands of their constituents, the election in many cases would be lost, so that it is clear that a hearing would not be refused by a politic member. I find, that in this part of the country, the public are generally willing to sign the petition which I have drawn up, and I now have *nine* petitions in the course of signature, to be presented to Parliament at an early period.

I should be glad to see the agitation which has begun continue until our objects are gained, for by importunity alone will the requisite concessions be granted.

I am, Sir, your obedient servant,
George Frederic Wills.

Crewkerne, Nov. 14th, 1849.

[We cordially recommend the example of our respected Correspondent for imitation by the Poor-law staff throughout the country. The most efficient mode of agitating the question is by influencing the votes at the elections; and we think, that if members of Parliament were made fully acquainted with the political power which the Profession are capable of exercising through their patients, there are very few members who would be indifferent to the interests of this highly useful and important section of the Profession.—Ed. *Med. Times.*]

THE USE OF CREASOTE IN BURNS AND SCALDS.

[To the Editor of the Medical Times.]

Sir,—The success attending the use of creasote in burns and scalds induces me, in case the treatment

should be new, to give, through your columns, an opportunity of its efficacy being further tested.

I have constantly employed it since I have been resident at the Queen's Hospital, and my conclusion is, that it is superior to every other application. It removes the pain,—it prevents the offensive smell always attending the old mode of treatment,—and the cure is much more rapid. Where the cuticle is unbroken one application is generally sufficient; and where it is destroyed, the cure is effected much sooner than by the common mode of treatment.

The mode of application is to brush the parts over with a feather once a day, and to prevent them from contact with the bed-clothes. No other application is necessary or proper, in conjunction with it. In burns of the face, by the explosion of gunpowder, its curative power has been marked by universal success.

My experience has not yet been sufficient to assert its superiority over every other treatment; but quite sufficient to justify a more extensive trial of its efficacy. Of its *modus operandi*, I am not sufficiently satisfied to offer an opinion.

I am, Sir, your obedient Servant,
J. B. STEWARD, M.D.

Queen's Hospital, Birmingham,
Nov. 16, 1849.

FELLOWSHIP OF THE COLLEGE.

[To the Editor of the Medical Times.]

SIR,—As you have had the kindness occasionally to give publicity to my letters, I beg to offer a few remarks on a matter which you have noticed in this day's publication, as follows:—"The Fellowship.—We understand that in consequence of the new regulations from the College coming into operation in the ensuing year, making it compulsory on all junior candidates presenting themselves for the honour, to undergo examinations in classics and mathematics, a larger number than usual will present themselves for examination at the ensuing meetings on the 4th and 6th of December."

The proceedings of the Council of the College have been marked of late as being altogether unjust; and I need not, I think, try to enlighten your readers when they already are so, or ought to be, on this matter.

I shall, therefore, confine myself to the Fellowship. All admitted as fellows hitherto have been examined only in anatomy, physiology, and surgery, or have been admitted because, through party influence, they have held what is called honourable posts in large hospitals. After the lapse of years, a few years only, a new regulation is introduced, *i.e.*, a classical and mathematical examination must be passed.

With respect to the last subject, I will not say one word in opposition to the necessity and use they may be to those who are connected with a learned profession; but I will say that they are of second importance to a thorough knowledge of the art and science of physic and surgery. In the practice of these arts and study of these sciences the classical knowledge, *i.e.*, the knowledge of Greek and Latin, is little used. Why, therefore, it may be asked, require candidates to be examined in these at all, at the late period, as will be soon required? A man at twenty-six will have left school generally ten years before he attains that age, and, consequently, unless he keeps up his Greek and Latin, by pouring over some learned work in these dead languages month after month for the ten years in question, he will have forgotten almost how to translate; and, therefore, if he wishes to present himself for examination for fellowship, he will have recourse to the readiest means for getting up his classical knowledge, which will be fleeting.

Now, in a former letter on medical education, I have stated that a man who enters the Profession ought to undergo a classical examination as soon as he leaves school, and have done with this bore for ever. Then, and then only, will he be fit to follow the prescribed routine of study with pleasure, and when he has passed his examination for medical honours he will be better prepared for the practice of his Profession.

By these remarks I wish to show, that it is unjust to ask those who have previously passed the College, even up to the present year, and it may be beyond, to undergo a classical examination such as will be required. I have no doubt that many who would have availed themselves of the Fellowship, had the examination to be conducted as heretofore, will now be prevented. They will not rub up Greek, and Latin, and mathematics for such a bauble. I moreover do not hesitate to assert, that many a man will be rejected for his classics, when he is thoroughly competent, as a surgeon, to be recognised as a Fellow. Still more, I assert, that many a hard-working student, when he passed his examination for Member, would have been able to have undergone the examination for Fellow, and passed it without the least difficulty. Still, those who passed in the successive years of 1846, 47, 48, and 49, will be unable to obtain the honour of a Fellowship, without undergoing a classical examination, which ought to have been instituted shortly after he left school, when his mind was fresh with the dogmas of the ancients.

If an examination was instituted in reference to the modern languages, as French and German, which would be far more useful, far more easy, far more agreeable, it would be preferable. A man then could visit France or Germany, and, while he was learning these languages, he could, at the same time, be improving himself in the Profession; and not only so, but intercourse of this kind between the students and Professors of different nations would be productive of friendship, and assist in bringing about that peace era, which is so much desired, and now so eloquently advocated by the ablest men of the present day. Hoping this imperfect letter will have effect in causing that state of things, or at least assisting, which is so desirable in the College of Surgeons of England,

I am, Sir, &c.,

Nov. 10, 1849. A REFORMER OF ABUSES.

COMMUNICABILITY OF CHOLERA.

[To the Editor of the Medical Times.]

SIR,—After reading Mr. Ebsworth's paper on the "Communicability of the cholera poison from man to man," I was induced to send you the following cases, hastily thrown together, as confirmatory of that gentleman's opinion.

The disease was first brought into my district by John Sandoe, a miner, who took the disease from some members of his son's family, where he lodged about seven miles from his own, a detached house having an open though low and damp situation.

Case 2.—Elizabeth Hore, aged 19, a strong, stout and healthy young woman, lived with her parents in an isolated house, about 500 yards from Sandoe's was employed by Sandoe's wife to work in the fields to assist her in the performance of her household duties, and to occasionally nurse her husband; whilst so engaged, took the disease and died.

Case 3.—Joseph Sandoe, aged 35, son of Case 1, lived with his parents, and occasionally waited on his father, was seized with vomiting, purging, and cramps, on Saturday, September 1, at 6 a.m. I was not called to see him till 7 p.m., when I found both them and son in the same bed collapsed; the father recovered, but the son died at 8 p.m.

Case 4. Jane Hore, mother of Case 2, whilst washing the clothes and bedding her daughter died in, was seized with cholera and died.

Case 5.—Jane Sandoe, wife of Case 1, was seized with cholera, September 3, and died in 76 hours. I may state that this woman had not gone into the dormitories after her son died, but was removed into a barn.

Robert Woolcock, who lived in an isolated house, situation low and damp, was seized with diarrhœa on the 26th September. He took no medicine till October 4, when he was seized with vomiting and cramps, and died on the 5th. His sister, Agnes Northay, nursed him during the collapsed stage of the disease, and remained in the chamber nearly an hour after he died. She was then, and up to the night of the 8th, in perfect health, when she was seized at her own house, a mile and a half from Woolcock's, with vomiting, purging, and cramps, and was collapsed in twelve hours; re-action, however, took place, and she continued to improve till the morning of the 11th, when vomiting and purging recurred, and she died about 5 p.m. Her only nurse was her sister, Mary Woolcock, who lived about 500 yards off, in an elevated and dry house; took the disease during the night of the 13th, and died after about twelve hours' severe suffering.

—— Burrows having been in communication with a person from Mevagissey during the prevalence of cholera there, was seized with cholera two days after, viz., Friday (noon), 31 August, and died without medical relief, at a quarter to 12 p.m. On the 4th September, the mother-in-law of the deceased, who lived about a mile and a quarter distant, and had had no communication with the family for weeks previously, came to the house in her usual health, and whilst washing the clothes and bedding, was seized with cholera about 2 p.m., and died ere I reached the house. The husband also took the disease, but recovered.

The old woman's clothes were given to another old woman, who lived about a mile distant, and who kept them tied up for three or four days; and, whilst in the act of washing them, was seized with cholera, and very quickly died. With the etiology of the disease I have nothing to do at present.

That the disease is contagious and infectious when in the collapsed stage, I have no doubt, and that it may be communicated from "man to man" by a body dead of cholera, or by the bed clothes which have been saturated with the discharges from a cholera patient, is (to me at least) equally certain. Apologising for the length to which I have gone,

I am, Mr. Editor, yours faithfully,
JNO. MOYLE.

Chacewater, Nov. 5, 1849.

[To the Editor of the Medical Times.]

SIR,—On reading the opening paragraph of Mr. Ebsworth's lecture, in your last week's number of the *Medical Times*, in which he, with so much self-complacency, disposes of the deductions of the Board of Health, by "his experience of the last few weeks leading him to the conclusion that these deductions are fallacious, and their reports prejudicial to the public weal," I fully expected to find some strong facts in support of the opinions so unhesitatingly advanced. In this I was mistaken; for, on the contrary, his further statements are but a corroboration of the views entertained by the Board of Health, not one fact advanced militating against the epidemic character of the disease. The first case mentioned is that of Robert Stainforth, who visited Hull, where the epidemic was raging: he inspired the atmospheric poison, went home and died of cholera; "but others of his family who nursed him in his illness did not take it; no, perhaps a higher Power rewarded their assiduity and tenderness, and preserved them." The plain truth of this is, the disease not being contagious, and the epidemic not having extended to this place, no fresh cases occurred. The atmosphere here was pure, and the people nursing him did not inhale a similar atmosphere to that which caused his death. The next case he mentions is that of William Puiket, residing at Bulwel, who is attacked with cholera and dies. "How he took it, heaven knows." Why, the epidemic had come, the poisonous atmosphere penetrated his dwelling, and the dwellings of others, and death after death ensued, showing most distinctly the epidemic character of these attacks. He goes farther, and gives a yet stronger proof of the epidemic and non-contagious character of this outbreak,—"A man *passing by* the above houses daily to his dinner *takes the disease home in his clothes*, gives it to his family, two of whom die speedily!"

Dr. Clanny, in a communication of his, in your Number for October 27, assumes an endemic character for the disease; but it is difficult to make out whether by endemic he does not mean contagious. In my opinion, his statements in support of the contagious nature of cholera, are as fallacious and inconclusive as Mr. Ebsworth's. The disease assumed a sort of endemic character in Alnwick, being confined to a particular part of that town, persons visiting which part, either to see their dying friends, to wash the clothes of the sick, to coffin the remains of those who were dead, or merely passing through the vitiated atmosphere of the streets, have taken the disease after reaching their homes, removed from the seat of the epidemic; have died in their abodes surrounded by their relatives and friends, and have left no trace of the disease behind. These are distinct facts against the theory of contagion.

In Alnwick, the cholera broke out suddenly in the night of the 22nd of September, in different parts of the district already alluded to, and ten persons died in the course of the following day. Thomas Wood, of Lesbury, mason, was working in that part of Alnwick, and returned home to Lesbury, three miles distant, on the eve of that day, and in good health. Cholera attacked him through the night, and he died in a few hours. None of his friends nor attendants took the disease, nor has there been another case in Lesbury.

Alexander Armstrong attended his mother's funeral. She lived in Clayport-street, Alnwick, but died of paralysis. On the 24th of September he returned home to Amble, distant ten miles. On the night of the 26th he was attacked with cholera, and died in ten hours. The room in which he sickened and died was the sole apartment for himself and family, consisting of nine persons, yet none of these took the disease, nor any of the neighbours.

Ralph Ewart, his brother-in-law, attended the same funeral, returned home to Ancroft Moor, took the disease, and died nearly at the same time,—his solitary room containing also nine inmates. No other

case of cholera ensued. Sailors have come from an infected port into the port of Amble, and died there of cholera, without communicating the disease to any of the neighbouring sailors.

I saw much of the disease in the Old College of Surgeons' Hospital in Edinburgh in 1831. I have seen something, and heard more, of it in this neighbourhood, at this time, but have never been able to discover a well-authenticated case of contagion. The contagious or non-contagious character of cholera is a question of vital importance; and the contagionists must bring forward something more defined and distinct than the vague letters of Dr. Clanny and Mr. Ebsworth, before they can shake the opinion of the Profession as to the deductions of the Board of Health.

I am, Sir, your obedient Servant,
THOMAS LEITHEAD, M.R.C.S.E.
Warkworth, Northumberland.

SALINE TREATMENT OF CHOLERA.

[To the Editor of the Medical Times.]

SIR,—I have for some time intended to communicate to you the results of my experience regarding cholera, as it has fallen under my observation this season in Kingston, but circumstances have occurred to prevent me up to the present moment, when the perusal of Sir Alexander M. Downie's interesting letter, in your Number for September 22nd, from its seeming correspondence with my views, makes me feel it to be my duty to lay them before the public, through the columns of your widely-circulated periodical.

My experience in the treatment of Asiatic cholera, during its prevalence in Malta, in 1837, was sufficient to shake my confidence in the use of calomel in large doses in that disease. I had also reason to view with distrust the administration of opium, brandy, and other vaunted remedies, and I resolved, in my own mind, that if ever I should again be called to combat this formidable enemy, I should chiefly trust to the internal and external use of cold water, until some more probably efficacious plan of treatment should approve itself to my judgment.

I was first led to form a favourable opinion of the use of Dr. Stevens's saline medicine by the reports concerning its successful employment in the cholera of 1832, in the Coldbath-fields prison, contained in various numbers of the *Medical Times*; and in the very first case of cholera which occurred in this city, (and the first, I believe, which appeared in British North America this year,) as far back as the 13th of January, 1849, I gave a fair trial to the same salts, but in different proportions from those used by that eminent physician, viz., sesqui-carbonate of soda, 15 parts; chloride of sodium, 5 parts; and chlorate of potash, 1 part; and so gratified was I with the result, in that case, and in another, which occurred on the 3rd of May, that I some time after, and when the disease had become epidemic, addressed a letter to the editor of the *Argus*, one of the Kingston newspapers, recommending this remedy to the attention of the Profession, and giving directions for its use.

On the 27th of May the disease broke out in a village contiguous to Kingston, in a most aggravated form. The locality was one peculiarly obnoxious to disease, from vast accumulations of decomposing animal and vegetable matters outside the dwellings, the dirty and dissolute habits of the people, and neglect of ventilation. Nine-tenths, probably, of those who first suffered from the disease in this place died, and medicine was of no avail in lessening its fatality, or checking its progress. A violent thunder-storm was succeeded by a pause; and about a month afterwards, the cases which occurred were of a less untractable character. The plan which I followed in the treatment of the disease was the following:—To give three drachms of the saline powder, as above described, dissolved in a pint of cold water, in divided draughts, from a quarter to half a pint, every quarter of an hour, half hour, or hour, according to circumstances, premising a pill containing, of calomel, ij grs. capsicum, i. gr.; and opium, one-sixth of a grain allowing, at the same time, cold water for drink, or directing small pieces of ice to be taken into the mouth and permitted to dissolve gradually. (This mode of allaying thirst I preferred latterly, from a belief that it was more favourable to absorption.) If the extremities were affected with spasm, they were to be rubbed gently with a piece of ice till it melted, and the water thus produced was to be used in the same manner, so as to urge its admission into the absorbents by assiduous friction with the hand. In every case, as far as I can remember, with two exceptions, I interdicted the use of wine, spirits, and hot drinks, and both of these terminated fatally. Endeavours were used to obtain ventilation as far as practicable, and a light covering only was thrown over the body. Such was the general plan of treatment followed by me, and the basis upon which I uniformly acted. I did not, however, confine myself invariably to these means. In some instances the pill of calomel, capsicum, and opium, was repeated at intervals of two, three, or four hours. In some cases I administered Dr. Graves' pill of acetate of lead and opium, with the addition of a grain of capsicum, but not often; and in one case only of a drunkard, as far as I remember, with marked benefit. I sometimes gave quinine in large doses, united with turpentine, with advantage, where there was reason to apprehend the existence of worms. This mode of treatment I found successful in two children. Quinine and iron, as recommended by Dr. Bell, seemed also to be advantageous in a few instances. Packing in the cold wet sheet was resorted to in six cases of children, under twelve years of age; of whom four recovered and two died.

Towards the middle of the epidemic, (which commenced on the 27th of May, and terminated about the middle of September,) I began to administer the saline, combined with tartaric acid, in the state of effervescence, in the proportion of a drachm and a half of the powder, consisting of the ingredients above mentioned to fifteen grains of tartaric acid, each dissolved in about a quarter of a pint of water, and intermixed in the usual manner.

I think I may, within bounds, say that I have had 77 cases of real cholera under treatment, of which 24, or 30 per cent. died. Twenty of this number resided in houses badly ventilated, or exposed to noxious effluvia, or both, and all were debilitated from infancy or old age, insufficient nutriment, intemperate habits, uncleanliness of person, or some other cause. Of the total number of cases, I consider 41 to have been in a state of collapse, of which 22 proved fatal. Two died of consecutive fever, leaving 17 recoveries from collapse.

I find that I have used twelve pounds of carbonate of soda, three pounds fourteen ounces of muriate of soda, and twelve ounces of chlorate of potash, during the late epidemic, which would give nine drachms of the compound powder to each of the 77 cases attended by me, or three pints of the solution, (probably a pretty near average,) and leave 341 three drachm doses (a large proportion of which have been given with tartaric acid in the state of effervescence), for cases of premonitory symptoms, or symptoms of mere dyspepsia, none of which probably terminated in cholera. Had not these precautionary means been used, it is impossible to say how many of these cases, which may have amounted to a very considerable number, (but I cannot say precisely, as I kept no register of them,) might have become confirmed cholera.

I can hardly entertain a doubt that great benefit was derived from this medicine as a prophylactic. In my own family, it was familiarly used by the children, and was called the "fizzing powder." We placed great confidence in it, and I frequently had recourse to it, when fatigued, and suffering from sinking sensation in the stomach. Its use was instantaneously followed by a pleasant exhilarating feeling, pervading the whole system, from the centre to the extremities, and its presence in the blood was speedily announced by the secretion of mucus from the lungs having strikingly saline taste.

A symptom of cholera which I have seen noted by only one writer upon the disease, Mr. Busk, Surgeon of the Dreadnought, (*Medical Times*, March 1 1849, p. 386,) seems well worthy of careful investigation by future labourers in this department. I refer to the difference of temperature, as indicated by the thermometer, in the mouth and axilla. In three cases I found the following results:—

1st. In a woman, aged 22, who fell into collapse, and was about twenty-five hours without the pulse being perceptible, and forty-eight hours without secretion of urine, but recovered,—thermometer, in the mouth, 82°; arm-pit, 90°, first visit; and continued so for twenty-four hours, when it rose to 94° in both situations.

2nd. In a man, aged 32: first day, thermometer, in the mouth, 84°; arm-pit, 91°: second day, upon which the disease terminated fatally, in the mouth 82°; arm-pit, 94°.

3rd. In a man, aged 50, a drunkard, who died after six days' illness,—thermometer, in the mouth, 84° arm-pit, 92°; the greatest difference in favour of the cutaneous surface being 12°, and the smallest 8° and the temperature of the mouth and axilla corresponding with each other upon the subsidence of the disease.

These facts seem to possess a peculiar interest, when taken in conjunction with the following observations of Dr. Bell:—"If one apparently dead of cholera became warm from the extremities upwards, no doubt of death can exist, and no chance of recovery; if this does not take place—on the contrary, if warmth proceed from the trunk to the extremities, there is a possibility that he may be alive." (*British American Journal of Medical Science for March*, 1849.)

I have treated cases of collapse very much upon the principle of frost-bite; and I have had no cause to exchange cold for hot applications to the extremities. It may be noticed, that ice produces a vivid red colour of the skin of some duration, such as I do not remember to have seen from hot applications in this disease. Blueness of the skin I have not remarked in the collapse of infants.

En passant, I would solicit attention to the question, whether cholera may not be divisible into varieties, as connected with hysteria, vermes, &c., each of which may possess distinctive symptoms, and require a peculiar mode of treatment. Lumbrici have been evacuated by vomiting and stool in several instances which have come to my knowledge, and one old woman who recovered from a most severe form of the disease, passed a large number of them when convalescent.

I attended many cases of the "Emigrant Fever," as it was termed, in this place in 1847. It prevailed chiefly in the same suburbs as the cholera of this year; but the greatest number of fatal cases did not occur precisely in the same houses or streets. About one half the inhabitants of three houses in one street fell victims to that malignant epidemic; but I have not heard of any persons dying of cholera within the same walls this year. Nearly the same proportion of deaths occurred in my practice in the epidemics of typhus and cholera.

Upon the whole, after a dispassionate review of both these epidemics, in which I have borne a part, it seems to me, that the description of persons who have been the greatest sufferers has been very much alike in both. Need I attempt a delineation of them? They possess nearly the same features everywhere. They are such as are crowded together in filthy dwellings, breathing an impure air, whose bodies are hardly ever washed, whose food is spare and unwholesome, whose drink is often intoxicating, whose clothing is ragged and polluted, whose labour is at times extreme, but who frequently can obtain none, and consequently no means of subsistence; with pallid and shrunk, or bloated and livid faces, diseased viscera, emaciated and tremulous, or tumid and congested limbs; their minds corresponding with their bodies, corrupt by nature and habituated to vice, many of them "having no hope and without God in the world."

Sanitary reform is now loudly called for, and it is none of the least of your merits that you do so much to promote this noble cause of genuine philanthropy.

I remain, Sir, your obliged servant,
JOHN MAIR, M.D., Staff Surgeon, 2nd Class.
Kingston, Canada West, October 11, 1849.

[The statements respecting the saline treatment of cholera are very contradictory, but many of the failures of which we hear may arise from its being mixed up with other modes of treatment. We think it possible, that if Dr. Mair had trusted entirely to Dr. Stevens's method, the results would have been different.—ED. *Medical Times.*]

THE NEW FRENCH MINISTER OF COMMERCE.—The new Minister of Commerce under Louis Napoleon, in France, is Dumas, the celebrated chemist, head of the Faculty of Sciences, Professor at the Sorbonne, and Professor of Organic Chemistry at the School of Medicine. There would be considerable astonishment in England, if Faraday were appointed President of the Board of Trade.

ETHER.—A young lady in Berlin has recently lost her life from the exhibition of ether, prior to the extraction of a tooth. Every effort to restore animation failed. The operator was the dentist himself. It is said, that the punishment for the use of such means by an unqualified person is very severe in Berlin: in that respect the Prussian authorities act wisely. There should be a difference between the qualified and the unqualified practitioner. Unfortunately, such is not the case in England.

HYDROPHOBIA.—The *Monmouth Merlin* states, that a cow belonging to Mr. Rosser, of Penalt, died lately quite rabid. It was a milking cow, and, as Mr. Rosser's family had partaken of its milk, they all removed to the seaside for immersion in salt-water!

HEALTH OF LONDON DURING THE WEEK ENDING NOV. 17.

The total number of deaths registered from all causes during the past week, were 878, being a decrease on those of the previous week by 15, and showing also a diminution on the average of 5 previous years of 284. This number gives a proportion of 1 death to every 2512 inhabitants; and the Returns of ten years show that this low rate of mortality is unexampled at this season of the year, the increase of population considered. The mortality in the early part of November has usually ranged from 900 to upwards of 1200 deaths. The mortality from phthisis and bronchitis seems to increase, and is now about the average; and influenza was fatal to 4 young persons and 1 adult. The principal decrease occurs under the head of zymotic diseases, the deaths being under those of a five years' average by 103.

The mean height of the barometer in the week was 29·863. The reading at the beginning of the week was 30·17 in.; it increased to 30·20 in. by 10 h. a.m. on the 11th; decreased to 29·47 in. by 3 h. p.m. on the 14th; and increased to 30·19 in. by the end of the week. The mean temperature of the week was 45·2; on Saturday it was at its lowest, 39·3; and at its highest on Sunday, 50·5. The result on the week is a plus of 1·0 over the average of 7 years. The mean direction of the wind was S.W. till Wednesday, and N.W. from Thursday. The difference between the dry and the dew point temperature was 4·2. The highest temperature of the water of the Thames, for the week, was 48·3, and the lowest 45·4. No electricity was indicated throughout the week.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Nov. 17, 1849.

CAUSES OF DEATH.	Total.	Average of Five Autumns.
ALL CAUSES	878	1162
SPECIFIED CAUSES	876	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	204	307
SPORADIC DISEASES:		
Dropsy, Cancer and other Diseases of uncertain or variable seat ...	43	49
Tubercular Diseases	166	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	108	125
Diseases of the Heart and Blood-vessels	33	40
Diseases of the Lungs, and of the other Organs of Respiration	154	211
Diseases of the Stomach, Liver, and other Organs of Digestion	50	65
Diseases of the Kidneys, &c.	7	11
Childbirth, Diseases of the Uterus, &c.	6	10
Rheumatism, Diseases of the Bones, Joints &c.	8	8
Diseases of the Skin, Cellular Tissue, &c.	5	1
Malformations	2	4
Premature Birth and Debility ...	21	23
Atrophy	21	18
Age	28	57
Sudden	11	12
Violence, Privation, Cold, and Intemperance	29	36
Causes not Specified	2	4

The following is the number of Deaths occurring from s of the more important special causes:—

Apoplexy......	22	Heart	31	Phthisis	
Bronchitis ...	62	Hooping-cough	22	Pneumonia ..	
Cholera........	8	Hydrocephalus	22	Scarlatina	
Childbirth	3	Influenza .		Small-pox	6
Convulsions...	32	Liver	11	Stomach	3
Diarrhœa......	21	Lungs	4	Teething	8
Dropsy	18	Measles	24	Typhus	12
Erysipelas ...	13	Paralysis	22	Uto:

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of Gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Wednesday, 14th Nov., 1849:—Richard Allanson Gaskell, St. Helen's, Lancashire; George Alfred Sheppard, Worcester; David Purdie Maclean, Burton, Westmorland; Lionel Smith Beale; Philip Henry King, Grantham, Lincolnshire; James Wannes Saunders, Aylsham, Norfolk; William Henry Welsh, Eccles, Lancashire.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen having undergone the necessary examinations for the Diploma, were admitted members of the College, at the meeting of the Court of Examiners on the 16th instant:—Messrs. Thomas Pettit Wright, Chatteris, Cambridgeshire; John Anderson, Old Kent-road; Herbert Taylor Reade, Quebec; Edward Egan, Dublin; Armstrong Todd, Dublin; Benjamin Webster, Morley-lodge, near Leeds; James Shepherd, Northallerton, Yorkshire; William John Tennant, Dublin; and Edward Golledge Pitt, Brunswick-place, City-road.

MEDICAL BENEVOLENT FUND.—We have received the following Circular, to which we desire to give as much publicity as possible:—

"Newport Pagnell, Nov. 6, 1849.

"MY DEAR SIR,—I beg to inform you, that a General Meeting of the Subscribers to the General Medical Annuity or Relief Fund Society will be held on Monday, November 26th, 1849, at four o'clock, at the Hanover-square Rooms, London, and I am especially to request your attendance. The business for which that meeting is convened is of the highest importance. An elaborate Report has been prepared by the Committee, and now forwarded to you; and, in accordance with the recommendation contained therein, it is intended to propose—

'1. That all rules and regulations hitherto in force shall be rescinded.

'2. That the designation of the Society shall be changed to the National Medical Annuity and Relief Fund Society.

'And 3. That a Provisional Committee be appointed, to frame and organize the Society on the plan sketched out in the Report.'

"Should it unfortunately happen that you cannot favour me by your presence on this occasion, may I request a line from you expressing your opinion of the proposed arrangements, and especially to permit me to enter your name as a member of the Provisional Committee to be then formed.—I remain, my dear Sir, yours very faithfully, EDWARD DANIELL."

[We earnestly entreat our readers to attend this meeting, at which we understand matters of the first importance will be discussed.—ED. *Med. Times.*]

JOHN HUNTER, F.R.S.—Captain Sir Everard Home, Bart., having presented an original drawing by Sir Nathaniel Holland of this distinguished physiologist, to the Council of the Royal College of Surgeons, those gentlemen lost no time in placing it in the hands of Mr. Maguire, who has produced an admirable *fac simile* of the illustrious original, which is allowed by the few remaining friends of Hunter to be a very faithful likeness of the founder of the Hunterian museum. We have no doubt the Profession will agree with us, that great credit is due to the Council for bringing out this portrait of a man to whom we are all so much indebted. Mr. Stone, the librarian of the College, is also continuing his series of portraits of distinguished living medical men. We have just received those of Mr. Henry Hancock, Surgeon to the Charing-cross Hospital, and President of the London Medical Society, and his colleague at the hospital, Mr. John Avery. Both are faithful likenesses of the originals, particularly that of Mr. Avery, and are well calculated to increase the reputation of Mr. Maguire.

IMPORTANT SANITARY EXPERIMENT WITH PEAT CHARCOAL.—The town of Windsor having experienced the fatal effects resulting from want of efficient drainage, has resolved to take most decisive steps for guarding against future evils. The local Board of Health having determined on the plan proposed by Mr. Jasper Rogers for their sanitary improvement, as well for its chemical as its commercial advantages, have placed that gentleman in communication with Capt. Vetch, R.E., with the view of the drainage being adapted to answer all purposes. A complaint being made to them by Mr. Lamb, of Peascod-street, that his house was scarcely bearable from the horrid effluvium that filled it, several members of the Board, in company with Mr. Rogers, proceeded to inspect it. The stench was described as most offensive, and the paint was perfectly discolored from the sulphuretted hydrogen emitted. The inmates must have been inured to it by degrees, or life must have been sacrificed. Two of the inspectors suffered for several days subsequently, from general derangement of system and irritation of throat. The fetor arose from a large cesspool at the back of the premises, the odour from which appeared to be drawn up by capillary attraction, and the heat of the chimney, to the house in question; the cupboards on each side of the chimney were disgustingly offensive. Mr. Rogers was requested, if possible, to purify the house, until the origin of the nuisance could be removed. Prepared peat charcoal was placed against the walls by his direction, and in half an hour after the operation the stench was removed, and the atmosphere rendered pure. The gratitude and astonishment of the inmates were great. They had for some time been suffering under fever and the usual distressing circumstances attendant on a vitiated atmosphere. Mr. Rogers strongly advises the application of similar charcoal to churchyards in close localities, and wherever danger is to be apprehended from the escape and admixture of any deleterious gases with the air.

CHURCHYARD DESECRATION.—A Committee appointed by the directors of the poor of St. Pancras, have been taking evidence with respect to the desecration of graves practised in St. Giles's Cemetery, adjoining their workhouse. The witnesses who were examined were persons connected with the workhouse, and they detailed facts similar in all respects, with respect to the desecration of the dead, to those recorded by Mr. Walker in his "Gatherings from Graveyards." The books of the Cemetery, it was stated, showed, that within the last three years and a half no less than 10,000 bodies had been interred there, 3000 of which had been buried within the last six months. The Report of the Committee added, that the extent of ground was little more than an acre. The Directors have resolved to appeal to the Board of Health to close the burial-ground of St. Giles.

THE WELLS IN MARYLEBONE PARISH.—An application has been made by the Marylebone Vestry to the new Commissioners of Sewers, to repair the damage done by the late Commissioners, who, by their system of flushing the sewers, have caused the sewer water to burst through and poison a well at the workhouse, one in Newman-street, and two in Wells-street, Oxford-street; the consequence being, that severe illness followed in some instances from drinking the water. Specimens of the water were exhibited at the meeting of the vestry: it was of a dirty-greenish colour, and looked exceedingly filthy.

THE TEA-PLANT.—The cultivation of the tea-plant has been introduced into South Carolina, U. S., and has proved successful to a certain degree. Dr. Smith, who introduced it, is of opinion that in fourteen of the States it could be successfully cultivated. One acre of ground will yield 547 lbs.: 111,520 acres of land, therefore, will supply sufficient tea for Europe and the United States.

SALE OF POISONS.—In Ashton, the sale of poisons is openly carried on in several public-houses. The weekly sale of narcotic drugs, such as Godfrey's cordial, soothing syrup, &c., by fifteen vendors, is said to be, on the average, six gallons, two quarts, and one pint and a half. In Preston, twenty-one druggists sold, in one week, 28lbs., 5oz., 5dr. of Godfrey's cordial; 18lbs. 4oz. of infant's preservative; 16lbs. 9oz. of syrup of poppies; 1lb. 1oz. 6½dr. of opium; 7lbs., 8oz., 2dr. of laudanum; 9oz. of paragoric, making a total of 68lbs., 1oz., 5½dr. of narcotic drugs. The " pre-parations are only given, it is said, to en ble the mothers to work t the factory." They do so, by narcotising infant that their health is destroyed, and very often death follows th unintentional -hibition of too large do The sale of poisons ought to be placed u de re restrictions. It is horrible to contemplate the ount of mischief that every day follows their te asy sale at present. The poisonings in Essex and Norfolk give fearful evidence of the readiness with which the most deadly poisons can be procured, while the immense increase in the number of murders shows, that the fear of death at the hands of the executioner i navailing to deter persons from the commission of crime.

ALLEGED DEATH FROM IMPURE VACCINE LYMPH.—An inquest has been held at Clerkenwell, on the body of an infant four months old, who was alleged to have died from the effects of impure vaccine lymph. The verdict returned was, "That the deceased died from erysipelatous inflammation, which had been produced by a puncture on the left arm for vaccination, and they (the jury) were of opinion, that there was a want of sufficient care on the part of the operator." The Coroner was Mr. Wakley.

INDIAN APPOINTMENTS.—Dr. Montgomery, late of the Bombay Medical Board, and Superintending Surgeon, J. Doig, return to England. Dr. Boyd, Medical Store-keeper, has succeeded Dr. Doig as Presidency Superintendent Surgeon. Dr. B. P. Rookes, Garrison Surgeon, has been appointed an Officiating Superintending Surgeon, and posted to the Southern division, during the absence of Dr. Straker, on field service at Peshawur.

MILITARY APPOINTMENTS.—22nd Foot.—Assist.-Surg. Andrew Leith Adams, M.D., from the 64th Foot, to be Assist.-Surg., vice M'Grath, deceased.—56th Foot: Staff-Surg. of the 2nd class, Luke Barren, M.D., to be Surg., vice Cowper, who resigns.—64th Foot: Assist.-Surg. Edward John Kennedy, M.D., from the Staff, to be Assist.-Surg., vice Adams, appointed to the 22nd Foot.—3rd West India Regiment.—Acting Assist.-Surg. Robert Thomas Dealiens to be Assist. Surg., vice Sanders, appointed to the Staff.—Hospital Staff.—Staff Assist.-Surg. Charles Bush Hearn to be Staff Surg. of the 2nd class, vice Barren, appointed to the 56th Foot. Assist.-Surg. Henry Shearly Sanders, from the 3rd West India Regiment, to be Assist.-Surg. to the Forces, vice Hearn, promoted. Acting Assist.-Surg. Edward Touch, M.D., to be Assist.-Surg. to the Forces, vice Kennedy, appointed to the 64th Foot.

OBITUARY.—On the 16th inst., in the 87th year of his age, Robert Batty, M.D., of Fairlight Lodge, near Hastings.—Henry Mathias, assistant-surgeon on board the Enterprize. Died from consumption, preceded by hæmoptysis, during the late expedition in search of Sir John Franklin.—On the 16th inst., at Chester, Thomas Bagnall, M.D., aged 65.—On the 19th instant, Dr. Allen, of the Royal Navy. This unfortunate gentleman committed suicide by throwing himself under a railway engine at the South-Western Railway. He had recently returned from Scotland to take charge of a convict-ship, which, however, he had declined doing, in consequence of ill-health.—Aged 46, Mr. Thomas Pitcairn, surgeon, Bedford-street, Toxteth-park, Liverpool. On Monday week, aged 80, Cabel Crowther, Esq., M.D., of Wakefield.

KING'S COLLEGE HOSPITAL.—In the Report of this Hospital, at the meeting, on Friday last, it was stated, that three-fourths of the proceeds of a sermon delivered at Lincoln's-inn Chapel, on the day of Thanksgiving, were about to be applied towards liquidating the expenses of receiving and treating cases of cholera and diarrhœa, during the prevalence of the epidemic. It appeared, that 1339 patients had been treated, of whom upwards of 400 had applied during the night, causing an addition both of medical officers and nurses to be required for the service of the Institution. A fifth donation of 100l. from Mr. E. M. Chandler was also announced, as well as other sums from other charitable individuals.

UNIVERSITY COLLEGE.—Dr. Garrod has been appointed to the Professorship of Materia Medica and Therapeutics at University College, vacant by the death of Dr. A. T. Thomson.

BENEVOLENT DONATIONS.—Mrs. Curtis, of Walsall, has presented the sum of 200l. to each of the following Charities:—The Walsall Lying-in Charity, the South Staffordshire Hospital, the Stafford Infirmary, the Stafford Lunatic Asylum, the Birmingham General Hospital, Queen's Hospital, Birmingham, Asylum for the Deaf and Dumb at Birmingham, Asylum for the Blind at Birmingham, and the Birmingham Eye Infirmary.

IRISH APOTHECARIES COMPANY.—The Governor and Court of the Irish Apothecaries' Hall, with the view to improve the knowledge of their candidates in pharmaceutic and pathological analysis, propose a prize of five guineas to students during their apprenticeship, which the Governor and Court will award to the most expert and successful competitor in the analysis of the subject selected for the year. The subject to be competed for in the year 1850 is the metallic preparations of the Dublin Pharmacopœia, (forthcoming edition,) and in connexion with these, the various mineral poisons, their classification, the symptoms produced by them, the appearances on dissection, the mode of detecting their presence in simple or mixed substances, solid or fluid, in the contents of the stomach or bowels, or in the tissues of the body, and their chemical antidotes. The examination will take place at the Apothecaries' Hall, upon the first Monday and Tuesday in May, and candidates for the prize are required to send their names to the Secretary of the Court a clear month before the day of examination.

THE CHELTENHAM BOARD OF GUARDIANS. This Board, already somewhat notorious for its attempted tyranny in the case of a late Medical Officer, (Mr. J. Hyett,) is still pursuing the same policy, in a still more obnoxious and less justifiable spirit. Ever on the alert to honour their Medical Officers, they have now come to the following resolution:—"That this Board is of opinion, that the system of medical relief at present in operation, is susceptible of considerable amendment; and this Board resolves, on account of circumstances recently brought to its notice, that, at the general election, in March next, no gentleman holding any hospital appointment shall be eligible as a Union Medical Officer.' This "new move" is directed against W. P. Brookes, M.D., who has, for many years, been an Officer of the Union, without the shadow of a complaint, and who has also, for a number of years, held an honorary hospital appointment with equal credit. Surely legislation ought to interfere, and protect Medical men from this petty tyran

THE ST. PANCRAS MEDICAL OFFICERS.—Two of the medical officers of the parish of St. Pancras have been severely censured by order of the vestry on charges of neglect. The first of these, Mr. Home Popham, who had officiated previously in charge of the cholera cases at Tooting, was charged with having neglected the case of an infant, said to have had cholera at the time; but the evidence that was brought forwards, clearly proved that Mr. Popham had nothing to do with the matter, the application for medicine having been made to his assistant, who refused to supply it, unless it were paid for. The child, when brought to Mr. Popham's house, was asleep; and the only complaint of illness made by its mother, was, that it had vomited twice. On the charge, although the act of neglect was committed by the assistant, who was dismissed by Mr. Popham for so doing, the latter was severely censured, and ran great risk of losing his appointment, several members of the vestry being very urgent for his dismissal. The reason for this harsh sentence was, that a master is answerable for the conduct of his servant—a regulation certainly according to law; but, in this case, as certainly not according to justice.

TESTIMONIAL TO MR. E. T. ALLEN, OF YORK.—The working-classes of York, residing in the "Three Water Lanes," have, much to their honour, presented Mr. E. T. Allen, surgeon, with a silver snuff-box, for his indefatigable Professional services during the period of cholera sickness in these localities.

TO CORRESPONDENTS.

"Mr. Couch, of Penzance," writes us:—"I observe, in Professor Owen's Lecture, reported in your last Number, that the metamorphoses of the crustaceans is ably and concisely discussed. In the first section of the first column, p. 373, your reporter says, 'It is certain, that the mouth of the young crawfish is not at any period accompanied by a marked change in the form of the body, or in the function and structure of the locomotive members," &c. This crustacean, in short, undergoes no sudden metamorphosis. If, by the common crawfish, is meant *Palinurus vulgaris*, as I suppose it is, the remark is, I think, a mistake. That species undergoes precisely similar changes to the lobster, &c., *vulgaris*. Its eyes are sessile, legs natatory, &c. My figures indicate it,—my notes describe it so. If, however, the remark is accurately reported from the Professor's Lectures,—lectures of which it is impossible to speak too highly,—I will re-investigate the subject immediately I can again get them in spawn."

[In reply to our esteemed Correspondent, we beg to state that the term "crawfish" was used by Professor Owen in the sense in which it is commonly understood by English Naturalists, as applying to the *Astacus fluviatilis*,—the small fresh-water species described by Rathke, not to the rock-lobster (*Palinurus*.) In the *Penny Cyclopædia*, e. g., the reader is referred, under the head "Crawfish," to "Astacus," and in the latter article, p. 514, vol. ii., he will find, "The crawfish, *Astacus fluviatilis*, is to be found in the fresh waters of Europe," &c.]

"A Constant Reader" writes from Litchfield, as follows:—"I was bound to two surgeons (partners) in February, 184'; they are both of them dead, the last died about a week ago; and I wish to know, firstly, whether, after going through the requisite hospital practice, &c., I could pass at the Apothecaries' Hall without further apprenticeship; secondly, whether the wife of the last surviving partner has any legal right to withhold my indenture; and, thirdly, the amount, agreed to be paid as premium being £150, and but £110 having been paid, whether she can claim the remainder."

[In reply to the first query of our Correspondent, we think he had better apply to the Clerk of the Apothecaries' Society. It is probable that, if he can get a certificate from a surgeon of having pursued his medical studies for five years, the Society would, under the circumstances, grant him an examination. 2. The rule is, that the executors may make over the pupil to another medical man by an arrangement between the parties concerned. 3. We do not think the widow would, even if she could, claim the balance due.]

"Mr. B. C. Browne, of Tamworth," writes as follows:—"I shall feel obliged if you or some of your correspondents will kindly inform me whether it is possible for copper to be gradually taken into the system through the medium of the food, from that food being occasionally cooked with water that possesses sufficient copper to turn rice that is boiled in it green, as I have had five children in one family ill with a sub-acute species of peritonitis; three of them are dead, the remaining two in a state of great danger."

[The introduction into the body of copper, in the way indicated by our Correspondent, is quite possible, and we do not think it unlikely that the symptoms to which he alludes have arisen from its use. Analyses of the blood, the substance of the liver, or of the coats of the stomach, would be advisable in the cases that have proved fatal; and an examination also of the food should be made.]

"Mr. King's" communication "On the use of Hydrochloric Acid in Cholera," will receive our early attention.

"Dr. Henry Thompson's (of Tyrone)" interesting case of "Popliteal Aneurism cured by Compression," we trust our space will permit us next week to publish.

"Dr. Downing's" pamphlet on "Tic Doloureux" has been received, and will be reviewed as soon as possible.

"Mr. Cooper, of the Medical Staff, Fort Pitt," must accept the same answer that we have given to many other respected Correspondents. The completion of Mr. Wardropp's work on the Heart does not depend upon us further than it will certainly be brought to a conclusion in the present volume. Mr. Wardropp is furnished with a certain number of copies for publication; but we are not aware at what price the author intends to issue them.

"O. Z."—The matter has been placed in the hands of a gentleman who may be relied upon, and who will communicate privately with O. Z.

Our friend in Oxford street, who inquires "the number of dispensaries where advice is given to the poor gratuitously," must pardon us that we do not obtain the information he requires. We have not time to do so; and, if we had, we do not know how to set about it.

"Sarsus."—We are unwilling to publish anonymous "Cases." In the present instance especially, we see no reason why the author's name should be suppressed.

"Mr. Robert Annan, of Kinross," will kindly accept the crowded state of our columns as our apology for delaying the insertion of his interesting "Example of Sympathy of Parts."

"Dr. William Hale, of Exeter," writes as follows:—"I beg to correct an error which has crept into 'the Notice to Correspondents,' in the 'Medical Times' of the 17th inst. It is there stated, that 'Dr. C. W. Bell, of Manchester, lately read before the Devon and Exeter Pathological Society an excellent paper on the present epidemic.' Dr. Bell's valuable time is too much occupied to enable him to visit Devonshire for the purpose of reading papers before the Pathological Society of Exeter. 'The Paper' is a letter addressed to me by Dr. Bell, which was, with the highly talented author's permission, read before the Society in question by the Secretary, Dr. Massy, who had requested me to allow him to do so."

Dr. Ure's" communication on the "Kenilworth Sewers and the Pimlico Tragedy," reached us too late for insertion.

Dr. Davies's" letter on "Cox, Davies, and Silk, *versus* the Midland Railway Company," shall appear next week.

Dr. Fleming's" obliging letter has been received.

ORIGINAL LECTURES.

INTRODUCTORY LECTURE

DELIVERED ON THE 21ST OF NOVEMBER, ON OPENING THE CLASS OF

THERAPEUTICS AND MATERIA MEDICA,

IN QUEEN'S COLLEGE, CORK.

By Professor FLEMING.

In commencing a course of lectures on Therapeutics and Materia Medica, it is essential that I place clearly before you the important ends contemplated in this department of medical instruction, and also, that I endeavour to imbue your minds with the true spirit in which this science should be studied. This is the more necessary, as in some Medical Schools the great objects of this course of lectures are altogether misunderstood, and hence the course of Materia Medica is not usually held by students in that estimation to which, as I will easily convince you, its real importance entitles it. Therapeutics is that branch of medicine which has for its object the treatment of diseases. In the early medicine was defined to be the art of healing, and, at this epoch, therapeutics was evidently the only object of medicine; but as knowledge increased, and observation became more accurate, it was found to be easier and more advantageous to prevent diseases than to cure them when developed. Thus medicine acquired a new science, called hygiene or prophylaxis, the object of which is, by maintaining health, to prevent the accession of disease. These two great ends of therapeutics and hygiene. viz., the cure of disease and the preservation of health, are accomplished by the employment of certain means or remedies, the consideration of which constitutes materia medica, the name by which this course is usually designated. It is, however, very far from my purpose to limit your attention to the mere description of drugs; on the contrary, that will be made quite secondary to what is of more value to you, therapeutics, which treats both generally and specially of the action of remedies on the body in a state of health, and their applications in the cure of disease.

In its most extended signification Materia Medica embraces all remedial agents of whatever kind, and thus includes mental remedies, diet, exercise, many surgical operations, and lastly, pharmacological agents or medicines properly so called. It is, however, more usually employed to designate that department only which relates to the consideration of medicines, in which sense it is synonymous with pharmacology.

You see thus that the limits of our subject are to some extent arbitrary, and, in fact, they are determined by conventional arrangements with the teachers of other departments of medical instruction, some subjects which might properly enough be discussed here, being omitted, as we know that they form part of other courses of lectures in your curriculum. * * * * *

I propose to myself, in conducting this course of lectures, to keep always distinctly in view what I believe to be its proper object, viz., the making you acquainted with the remedies of disease, their most effective form; and the most successful mode of applying them. With this principle to guide me, I shall have no difficulty in apportioning to each of the numerous subjects pressed on our notice, the amount of attention which it demands at our hands, and which will depend entirely on its subserviency in promoting the great end in view. We will enter very fully into the physiological action of medicines, on the knowledge of their effects on the healthy body, as we know that this knowledge is an indispensable guide to the administration of remedies in disease. Here I must take it for granted that you already possess an acquaintance with physics, chemistry, anatomy, and physiology. We shall avail ourselves of the sciences of botany, zoology, mineralogy, and chemistry for the description, preparation, and identification of the several articles that have obtained a place in the Materia Medica, studying the necessary parts of these sciences, not for their own sake, but for the purpose of applying the means of treatment during the actual presence of disease with greater certainty. You see thus, that for the succesful study of Materia Medica, much previous instruction, and more especially a thorough knowledge of all the elementary medical sciences is imperatively demanded. It is on this account that attendance on this class is fixed for the third year of your curriculum, and in adopting this arrangement, the authorities of the Queen's Colleges have wisely deviated from the ordinary course of study in force in England, where attendance on this class is required in the first or second year.

The closest relation exists between Therapeutics and every other branch of medical study. Our science forms, so to speak, the focus to which the light of all the others, is made to converge, the more effectively to accomplish the great aim of all your studies—the relief of human suffering.

It is in accordance with this view that Dr. Fleming proposes to adopt a physiological arrangement of the articles of Materia Medica—that is—an arrangement founded on their known effects on the living body; for it being allowed that the ultimate object of all our inquiries into the Materia Medica, is an attainment of the knowledge of the therapeutical uses of medicines, it appears to him that an arrangement, founded on the botanical, chemical, or other characters of drugs is, in relation to that important end, scarcely deserving of the name of a classification, and however imperfect our physiological arrangement must necessarily be in the present state of our knowledge, it is yet a step in the right direction, and, which, though involving errors, will, itself, render important aid in correcting them. The prevalence of a natural-historical classification, in our best works on Materia Medica, originates in a misapprehension of the proper character of this subject; but on this point, he said he would revert to fully in his next lecture, when he would exhibit the arrangement of the course.

In the meantime, this seems a fitting occasion for a few remarks on the present state of our science, and for pointing out to you the best method of securing its future progress. The Professor then entered into a philosophical comparison of the empirical and rational methods of advancing medicine. His observations gave evidence of the careful manner in which he has studied the fundamental principles of his favourite science. In the course of his remarks he alluded to homœopathy, as an illustration of a false rationalism, analogous to the so-called rational systems of Paracelcus, Van Helmont, Brown, and Broussais.

Even our own time, continued the Professor, has seen in homœopathy the birth, and I grieve to say the extensive diffusion of such a system. Seizing a fundamental truth in therapeutics, which I shall explain fully to you in my lectures under the name of substitutive medicine, the talents of Hahnemann raised upon it with much ingenuity a superstructure of considerable beauty, and which has captivated many weak minds. But it is not true, and a system which, a century ago, would probably have formed an epoch in the history of legitimate medicine, is now, from the improved knowledg of medical men, repudiated as a mixture of truth, fiction, and quackery. * * * * *

At the present day, the practical turn of mind characteristic of medical men in this country has led to the disappearance from their medical literature of nearly all trace of the wordy dissensions between rationalists and empiricists.—These two sects have met ostensibly on common ground. Not so on the Continent, where the old feud, but in a very modified form, is waged as warmly as in the days of Celsus. This is most obvious in Germany, where controversies in all departments of science are cherished with passionate fondness. This country is peculiar in possessing numerous highly distinguished men who have made physiology and pathology their exclusive pursuit—practical medicine being left to another and distinct class of men. The professors of physiology and pathology, affecting to despise the unscientific practice of their more humble brethren, have, with Müller at their head, united themselves into what is termed the Physiological School of Medicine. It includes many distinguished names—as Henlé, Wunderlich, Skoda, and Rokitanski, and from its ranks have emanated some of the most important contributions to our science of modern times. Avoiding hypotheses and vain speculations, this school has devoted itself to rigorous observation. It has laboured with the microscope to unveil the mysteries of histology, with analytical chemistry to determine the changes induced by disease in our tissues and fluids, with experimental physiology to ascertain the action of drugs, and in all these channels of inquiry has earned for itself the warmest thanks of the Profession. But it has committed one grand error, it has under-estimated the importance of simple clinical observation, it has too contemptuously discarded the results obtained by the busy practitioner—it has become too exclusively rational, and some of its members have erred grievously in repudiating all therapeutic means not based on the doctrines of physiology and pathology. Nay, some of them some of them have gone so far as to deny altogether the utility of drugs as at present administered. So openly avowed is this doctrine, that in the wards of Scoda, Professor of Clinical Medicine in Vienna, I have seen patients affected with the most severe diseases as pneumonia, pleurisy, and fever, left entirely to nature, and, with the exception of some slight regulation of diet, not an effort made to avert the tendency to death should that event be impending. To express belief in the value of medicine in this capital is to expose oneself to ridicule. Although in Berlin, and some other German schools, medicine is practised as much in this country, still this utter scepticism of the value of drugs has made rapid progress throughout Germany. Homœopathy, Hydropathy, Mesmerism, and other quackeries have flourished in a corresponding degree. The busy practitioner, dependent for his livelihood on the pursuit of his Profession, has become alarmed—not having the leisure to study profoundly the sciences of physiology and pathology, and place himself on a par, in this respect, with the Professors in the Universities, yet honestly convinced of the real value of the treatment he is daily adopting—erroneously believing that the scepticism of the Professors is due in some way to their physiological and pathological studies, he has fled in desperation to the opposite extreme—has denied the possibility of founding practical medicine on a physiological basis, and has, within the last few years, unfurled anew the banner of empirical medicine.

At the head of this school, Rademacher stands prominently forward. His work, entitled "The Cultivation of Therapeutics on a Purely Empirical Foundation," and written to counteract the spreading scepticism of the rational school, has enjoyed a most extensive circulation, and has obtained for him many followers, who, though less known to fame than their opponents, are diligently occupied in collecting observations made at the patient's bedside.

A periodical entitled the *Journal of Medical Experience* has recently been founded to serve as the organ of this school.

Happily, a large section of the profession has avoided the extreme views of either the physiological or the empirical schools, and, judiciously blending science with clinical experience, is actively exerting itself to improve the difficult art of practical medicine.

In France the physiological school has reared its lofty head under Andral, Cruvelheir, and Bouillaud, with such power as to have thrown the therapeutist into the back ground. While the sciences of physiology and pathology, and the art of diagnosis, have made great progress in France, that of the uses of medicines has been completely overlooked. Disbelief in the value of ordinary treatment is very general, yet the extreme opinions of Germany find few disciples among the French. Under Chomel, Trousseau, Rostan, the French student has yet excellent opportunities of acquiring a knowledge of

practical therapeutics. The long and irregula neglect of this department of medicine in th country has at length forced itself on the attentio of the profession, and we can see indications of new and better state of things.

In relation to treatment, medical men in Great Britain and Ireland may be divided into two classes including respectively the scientific practitioner an the practical man. The first and smaller class is I am glad to say, rapidly increasing its numbers It includes all those who practise what we hav described, the true rational therapeutics, sometime designated as rationo-empirical medicine. The believe that physiology should form the basis o practical medicine, but at the same time they d not hesitate to receive curative indications from th bare facts of clinical experience.

The majority of medical men in this country contrast unfavourably with the class now described I refer to the routine practitioners, or, as they have been pleased to designate themselves, the *practical* men—who, from a want of study, of intelligence, or of time, affect a supreme disdain f everything that concerns doctrine or generalization. They pride themselves on their experience and speak ironically of the scientific practitioner, calling him a theorist or a book physician—but whose knowledge, they feel, crushes and confound them. "The so-called practical men," says Professor Craveilheirs, "are those who have no doctrine and no general principles, who gather t gether ready made formulas and isolated cases, without any kind of scientific discernment. Tl only medicine they study is that contained in small books of prescriptions, which they carry in their pockets, and know by heart. We have frequently had occasion to remark," he says, "that a practical man, that is, a man who boasts of knowing nothing of scientific medicine, is a medical machine, inferior, intellectually, to a master mason, a locksmith, or a cabinetmaker, for these have principles, and a sort of doctrine, which they apply in their business."

* * * * * *

The difficulties which surround our science are discouraging, and the picture of its past history is, I confess, gloomy. Now, however, it is evident that a new era in the history of medicine is gradually opening upon us, that in fact Therapeutics is beginning to attract that attention it so eminently merits, and we are justified in hoping that the next fifteen or twenty years will achieve for our science a rapidity of advancement to which it has hitherto been a stranger. It is to the rising generation of scientific practitioners that we must chiefly look for this onward progress, and let me hope that some of you are endowed with that activity and enthusiasm with which so much may be done for science, and of which it stands so much in need.

And now, gentlemen, allow me to say a few words on your responsible position as students here. It may be said emphatically, that everything in medicine relates or ought to relate to Therapeutics, or to express it otherwise, that all your studies are important only in so far as they improve your power of mitigating suffering, repairing injury, and averting death. Much of the information to be communicated here is of that kind which is immediately applicable at the bedside of your patients. You must, therefore, employ your talents to the utmost to make the best use of the present opportunity for improvement, or how can you afterwards enter honestly upon the practice of your Profession? You must labour hard now, if you desire, in the future, to enjoy the blessings of peace of mind and an approving conscience. * * The Professor here appealed to the student on behalf of the P fession he was about to join, and on behalf of the young College he had just entered. He concluded his truly excellent lecture in the following words: I trust that each one of you, when the time comes for you to go forth into the world and leave the place of your education, will be prepared to secure respect and success for himself, to maintain and elevate the character of his Profession, and to reflect honour on his alma mater.

ORIGINAL CONTRIBUTIONS.

RETROVERSION OF THE UTERUS AS A CAUSE OF STERILITY.

By EDWARD RIGBY, M.D., &c.; Senior Physician to the General Lying in Hospital; Examiner in Midwifery in the University of London.

In order still further to illustrate the subject of retroversion, as one of the many causes of sterility, to point out some of the more important effects which this displacement produces, and also to show the great value of the prone posture for maintaining the uterus in its natural position, I must be permitted to quote a case or two where it has occurred in unmarried females.

Through the kindness of my friend, Mr. Frederick Elkington, of Birmingham, I have been furnished with the notes of an interesting case which I attended with him two years ago at that place, and which I have had the opportunity of seeing occasionally since in London. His report is as follows:—

Miss ——, aged 36, a delicate lady, of nervosanguineous temperament, came under my care in August 1847. She had been suffering some months from hæmorrhagia, was very thin, much reduced, and in a very weak state, suffering from frequent alpitations of the heart, and a high degree of nervous excitement. I was informed that she had been subject, more or less for several years, to frequent ttacks of flooding, commencing at the menstrual eriod, and at times continuing for several weeks ogether. Sometimes the discharge would continue or three or four months with little or no intermision. She had pain in the sacrum and left iliac egion, sometimes in the right, a sensation of weight n the pelvis, constipation, and a feeling of pressure gainst the rectum. She dates the origin of her lness to long continued watching of and nursing a ear relation, supporting her and bending over her hours at a time. Whilst thus occupied, and luring one of her pe she first felt the above mptoms. On making an examination per vagi- I found the os uteri open, the lips swollen, the terus retroflexed, the fundus resting nearly upon he perinæum. On passing the sound, and raising he fundus, the uterus was restored to its normal sition, and tl appearance of a tumour removed. On withdrawing the sound the fundus again fell kwards, the uterus doubling upon itself. There pain and tenderness of the left ovary, (pressure ver it causing acute pain,) frequent hæmorrhage, metimes considerable, so much so, that on one casion I thought it necessary to plug the vagina. he was visited by Dr. Rigby, August 31, 1847, ho found her with constant discharge, frequently assing small coagula, but not to the extent she ad previously done; pain in the left inguinal region, hip, and sacrum, sometimes extending down the thigh; pulse quick, skin dry. On examination per vaginam, the uterus was found retroflexed; per rectum, the left ovary was felt enlarged, and painful on pressure. He advised the application of leeches to the ovary by means of the rectum tube, and repeated every third or fourth day, till the pain and tenderness were removed; afterwards to Professor Simpson's uterine supporter, to take an alterative pill at night, and a mixture with liquor taraxaci, &c. in the day.

She was much relieved by the application of leeches, and, after the third leeching, the pain and tenderness were entirely removed. The discharge, although not entirely checked, was considerably diminished.

The uterine supporter was first used September 12, and worn only a few hours. It was introduced he following day, and for several successive days, early in the morning, and removed in the evening. The first two or three days she could only wear it a few hours at a time, as it caused so much pain. She then wore it a few days without having it removed, but, having an attack of pain in the left ovary, from a return of inflammation, the supporter was withdrawn, the ovary leeched, &c. The pain being relieved, and the uterus continuing retroflexed, it was again introduced the first week in October. She then wore it eight weeks, during which time she was able to walk out a little, and to ride out most days. She suffered but little pain and inconvenience from it. At times there was a copious mucous discharge, and she lost a good deal at the two menstrual periods while she wore it. The periods were also prolonged, lasting 10 or 14 days. Every now and then, she had pain from the disc of the instrument getting into the os, which completely embraced it; but by pressing the os uteri upwards, and slightly drawing down the instrument, she was immediately relieved. Eventually this accident was prevented by the use of an astringent injection. She wore the instrument two months, but could not be prevailed on to wear it longer. She was without it six weeks. For two or three days after it had been removed, the uterus maintained its normal position; it then fell back again. At first it was not so completely retroflexed as before, but gradually became so. During the month of December, she improved in health, and regained strength; indeed she had done so whilst wearing the supporter, but complained of pain or aching in the sacrum, and a dragging in the groin, more particularly in the left; pressure against the rectum, with occasional discharge.

January 18, 1848.—She is better in health, but the uterus is still retroflexed. The menstrual period has just ceased, and she was anxious again to try the supporter. It was introduced, and she wore it without pain or difficulty; but there was a return of the coloured discharge, which continued more or less each day, at times accompanied by the discharge of small coagula, till the 27th. She then became so excessively anxious about the discharge, that I thought it better to remove the instrument, and the discharge gradually ceased.

February 2.—She is entirely free from discharge.

11th.—Has continued without discharge since last report; is improved in health; uterus still retroflexed. The vagina in a more healthy condition ever since I attended her; much less relaxed; the os uteri more closed. From the improved tone of the part, I thought there was a greater probability of the uterus being permanently restored to its normal position than there had been before, and a better prospect of the supporter being successful. I was anxious, therefore, to give it another trial. It was introduced without difficulty or pain, the os uteri closely embracing the peg. Soon after the instrument was passed, there was a slight return of discharge, which continued in some degree till March 1. It then ceased altogether, and she remained free until the 10th, this being her "poorly" time. When it was over, as she thought, two or three days, it again returned slightly for a few days. About the 7th, (viz., the 17th,) it increased considerably, accompanied with clots. She now became alarmed, and wished to have it removed, but was prevailed on to try it a little longer, in the hope that this discharge would subside. She has worn the instrument this time six weeks. I intended she should wear it, if possible, for four months, so as entirely to overcome the disposition or habit of the uterus to fall back again.

March 20.—The last two days she has had much less discharge; it generally gets worse in the evening and continues during the night; in the morning, when the bowels are moved, she frequently passes a small coagulum. She does not appear to have lost so much lately as to hurt her,—indeed, not more than many females do at each period; she complains of pain in the left groin, and a dragging sensation; bowels confined; they have not been moved so freely as usual for three or four days.

Examination per Vaginam.—The instrument has kept its place very well, it has not once been wrong this time. She was ordered to have an enema, and to have it repeated every day, if necessary; to use an alum injection per vaginam once or twice a day; to keep perfectly quiet for a few days, and to take Tinct. ferri sesquichloridi guttæ x. bis die ex aqua.

23rd.—Has rather less discharge the last two days, but some increase each night; complains of palpitations; pulse, 110. Tongue clean, but rough; pain in the left hip and groin, and also in the uterus; is hysterical, and has passed a good quantity of limpid urine; the bowels have been moved by the enema; she says that the discharge has been, at

times, offensive, and there has been a discharge of wind from the uterus.

Examination externally.—There is no enlargement to be detected in the situation of either ovary, nor of the uterus; nor is there any tenderness on pressure.

Examination per Vaginam.—The disc of the instrument is not close up to the os uteri; no tenderness on pressure of any part of the uterus or cervix.

Examination per Rectum.—No enlargement or tenderness to be detected of either ovary.

Let her have a warm hip bath at night, when in pain. Rep. tinct. ferri sesquichl. ℞ Extr. hyosc. extr. rhei, aa. gr. v. om. nocte.

25th.—Better; the pain was relieved by the bath.

28th.—Better; no pain on sitting up; less discharge.

April 15.—Is much better; has had no discharge since the 5th, yesterday. She took a long ride; it is now about the time of a menstrual period, and a slight show has appeared to-day.

April 24.—She reports that, since my last visit, she has had some discharge daily; but on the 21st, 22nd, and 23rd it increased: to-day she has had a copious flow, one or two gushes, and some clots; pain in the side, bowels disordered, being relaxed two or three times a day. I removed the supporter, which she has worn this time ten weeks and three days. The uterus is in its normal position, the os open and relaxed. She is to use the prone couch.

May 31.—I received a note from her this morning, stating that she had not been so well, and had had much pain and discharge. I found that she had been taking more exercise than usual, and that the bowels were constipated. Let her have an enema occasionally, and to keep quiet for a few days.

June 7.—The discharge ceased on the 5th; she has been entirely free since, and feels better than she has done for two years. I find that the position of the uterus varies considerably; sometimes it is normal, frequently partially retroflexed, particularly after taking exercise, *and then the discharge is more copious*; at other times, more especially after keeping the prone position for some time, it is antiflexed. She perseveres in the use of the prone couch several hours a day. Early in July she went to Ramsgate.

July 21.—She writes that she bore the journey well, and felt better; but the bowels had been much relaxed since her arrival there.

31.—She writes, "You will be glad to hear that I feel much better, and have got over my period very well."

August 25.—Writes, "I have got over my last period very well, and am certainly stronger. I hope the prone position may be as beneficial as it is expected. I give it a fair trial."

February 6, 1849.—Writes, "I am sure you will be glad to hear that I am now very well, and am getting quite strong. I still continue the prone couch, making it my habitual position, and always have recourse to it after taking exercise. I can walk two or three miles very well. It is no small comfort, I assure you, to have regained the use of my legs. I think, from my own experience, I may strongly recommend the prone couch to all similarly affected as I have been."

March 27.—Writes, "I am so well now that I hope I shall soon have no further use for the couch. I certainly think I have derived great benefit from the prone position."

After this last report, by Mr. Elkington, I saw her on two occasions, and made the following memoranda:—

April 14.—She has now used the prone couch for a year with striking improvement both in health and strength. I advise her to feel her way carefully in moving about; to use the prone position at least once a day, and always at night.

August 29.—Is well and active, but requires care to keep the uterus in its right position, especially just before the period; the menstruation is now quite healthy.

When I saw this patient for the first time she was in a state of great exhaustion, and considerable danger, having been literally drained of blood by previous and still recurring gushes of severe menorrhagia; every movement was followed by a fresh discharge. The loss had been so severe on one occasion, before I saw her, that Mr. Elkington had very properly plugged the vagina for a while; and when it was decided that I should be sent for the danger was so urgent as to admit of no delay. The two points which struck me, on investigating the case, as being essentially connected with the menorrhagia, were the retroverted condition of the uterus, and the inflamed and swollen state of the left ovary; both of them, separately or conjointly, were capable of causing menorrhagia, more especially the latter, as I have already shown in a striking case of this affection. (*Medical Times*, Feb. 15, 1849.) The retroversion was evidently the earlier affection; the characteristic pain at the sacrum and left side of pelvis were pointed out by Mr. Elkington in his very first report. They were attended with a sensation of weight in the pelvis, constipation, and a feeling of pressure against the rectum; symptoms arising from mere mechanical pressure of the fundus uteri against the posterior wall of the pelvis. The displacement had, doubtless, been produced by over exertion and long standing during a catamenial period, when the uterus, heavier and more bulky than usual, was more readily affected by efforts of the abdominal muscle, as in lifting, &c. It was after one of these occasions that she first perceived the pains connected with retroversion. We may presume that the inflamed and swollen state of the ovary was a consequence of the retroversion. I have repeatedly alluded to this fact; and here also it was the left ovary, as is observed in so large a majority of cases.

I found her in a state of serious exhaustion; considerable discharges of fluid and clotted blood were still recurring from time to time. She was not in a condition to bear the uterine supporter, and still less to bear the application of leeches for the present. I therefore directed a sort of prone couch to be made in her bed by pillows, &c., laid upon a box of the proper size; by this means I hoped to bring the fundus of the retroverted uterus forwards, (as the soft parts were thoroughly relaxed by the effects of the discharge,) and thus, in some measure, relieve the engorged ovary from the obstructed state of its returning circulation. I recommended Mr. Elkington to leech the ovary (per rectum) as soon and as frequently as he could, and, when the state of the patient permitted it, to apply Dr. Simpson's uterine supporter. The third application of the leeches completely relieved the inflamed condition of the ovary, and in not quite two weeks from the time when I saw her she was enabled to make a cautious trial of the supporter. At first she could only bear it for a few hours at a time, but soon increased the period to several days; a return of the oophoritis necessitated its removal, and another application of leeches. After this she was enabled to wear it eight weeks, with great improvement to her health and strength. She passed two catamenial periods while wearing the instrument; they were very profuse, and there was a considerable mucous discharge between the periods, probably resulting from the relaxed atonic state in which the uterus and vagina still were, and also from the irritation produced by the supporter. She suffered also from an accident, which not unfrequently occurs, and produces considerable pain, viz.: the relaxed os gradually descends over the button or disc of the instrument, and then contracts beneath, drawing down the fundus tightly upon the peg, and producing much suffering. The injection of some astringent is, I believe, the best means for preventing it; and the form of the disc ought to be oval, with its long diameter corresponding with the transverse one of the pelvis. The benefit from the supporter was but temporary in this case, but, nevertheless, it was of much importance to her, for it relieved her of those painful symptoms which evidently depended on the retroverted state of the uterus, and enabled her to gain strength, and to go out into the open air, which she scarcely could have but for its assistance. In such a state of debility and want of tone, it could hardly be expected that the uterus would retain its natural position when the instrument was withdrawn. Accordingly, as soon as this was done, she began to complain "of pain or aching in the sacrum, and a dragging in the groin, more particularly in the left, pressure against the rectum, with occasionally some discharge." This defective support of the uterus is well seen in some cases of retroversion, where the patient has used the prone position; for, after a while, instead of the above-mentioned symptoms of retroversion, she has pain in the pubic region, and frequent desire to pass water,—the position of the os uteri backwards, and the fundus directed forwards, indicating a state of anteversion, the fundus falling forward or backward according to the position of the patient. The fact of her having brought on a return of her symptoms, by over exertion, after about a month's use of the prone couch, shows that, at any rate, she had sufficiently benefitted by it to be able to get out and move about; but she had also increased the liability to a return of it, by allowing the bowels to become constipated. After this little interruption, she began to improve steadily, "persevering in the use of the prone couch several hours each day," and in little more than a month had improved sufficiently to venture on a journey to Ramsgate. I saw her as she went through London, and was much pleased to see what a favourable change had taken place. Her occasional reports of herself to Mr. Elkington show that the catamenial periods were now becoming natural, and that her health and strength were rapidly improving. She could evidently command the position of the uterus by using the prone couch, and her resolute perseverance brought its just reward. I will now add some further reports of this interesting case down to the present time.

April 14, 1849.—She called upon me in London. She has now used the prone couch for a year, with great improvement of health and strength. I advise her to feel her way cautiously as to taking exercise, to use the prone position once a day, and always at night.

August 29.—Is well and active, but requires care in order to keep the uterus in its right position, especially just before a menstrual period. Catamenia quite natural.

Nov. 16.—By a letter just received by Mr. Elkington, she says:—"I think I am as strong and well as ever I was in my life."

In advising her to continue the prone position at night, I was merely advising her to keep up the use of a position for sleep, which habit soon renders the most comfortable that a patient, under these circumstances, can adopt. She generally finds that she learns to sleep upon her face much sooner than she expected, and derives an amount of comfort which she seeks in vain in any other position. I believe I have already stated, that the prone position, in cases of retroversion, is most effective just before a catamenial period, when the uterus is heavier than ordinary, and where it is, therefore, more completely under the influence of position.

AN ACCOUNT OF SEVERAL CASES OF BILIOUS CHOLERA

TREATED BY

HOT-WATER APPLICATIONS.

By F. A. BULLEY, Esq., F.R.C.S.,
Surgeon to the Royal Berkshire Hospital, Reading.

Case 1.—Miss G., a maiden lady, aged 72, was seized on Monday, Sept. 10, 1849, with all the ordinary symptoms of the epidemic cholera. About two o'clock on that day, having been in better health than usual on the day previous, she suddenly felt exceedingly faint, and began moaning, as if from excessive pain. Immediately afterwards she became very sick, straining violently, but bringing up only small quantities at a time of a dirty, white, sticky fluid. She continued in this state, until four o'clock in the afternoon, when a diarrhœa, from which she had been suffering in some degree all that day, became much more frequent and harassing, until she was at length unable to retain the evacuations, which were fluid and light coloured,

and ejected with considerable force from the intestines. She was much in this state when I was called to see her, about six o'clock in the evening, with the addition, that her limbs had become exceedingly cold, and covered with a damp perspiration; her face, also, was cold and deathlike, with a peculiar hollow appearance of the eyes; pulse not perceptible at the wrists, with a very feeble action of the heart; tongue slightly coated with a greenish fur, and she complained of a most intolerable sensation of burning or gnawing at the pit of the stomach.

Thinking that not a moment was to be lost in attempting to restore the fast failing circulation, I had her immediately packed up with hot water in the manner described for the treatment of scarlatina in the *Medical Times* of August 25, (a) and her body afterwards covered with a great number of blankets, and she took the following draught:—

℞ confect. aromat. ʒ ss.; olei caryophyll. ♏ iv.; spirit. armoraciæ. comp. ʒj.; aquæ menthæ virid. ℥i ss. ft. haust.; which was almost instantly rejected.

This being the case, the medicine was not repeated, but she took about ten drops of a solution of the liq. morphiæ muriat. in a wine glass full of cold water every half-hour, which manifestly relieved the sickness, but did not entirely remove it. About the middle of the night, while still covered with the blankets, she was observed to bring up a considerable quantity of a fluid like thin coffee-grounds, and afterwards a small quantity of bile appeared in the matter vomited, which continued until the sickness had entirely abated. Although she began to feel warm from the commencement of the packing, it was nearly 1 o'clock in the morning before the perspiration became general over her body; and about three o'clock, it quite ran down her face, as the nurse informed me. She was then carefully and gradually uncovered, when she was found to be uniformly warm over her body and limbs; the distressing sensations in the epigastrium were no longer felt, and the pulse had recovered its natural healthy beat at the wrists, whilst the sickness had in a great measure subsided. An immense quantity of thick, dirty, white fluid was found to have been discharged in the bed clothes when they were removed from her body; but after this she had no evacuation of any kind, until a day or two afterwards, through the employment of medicine.

Tuesday (next day) evening.—She has passed a tolerably comfortable day; she is rather thirsty, the thirst having been previously very great; her skin continues quite moist and warm all over. There is no appearance of any re-active fever. The urine which, although small in quantity, had not been entirely suppressed, now passes freely. She has a trifling feeling of sickness at intervals, but is in no pain; she suffers a good deal from flatulence. Her bowels have not been opened since yesterday, when the blankets were removed; she has felt as if she wanted to relieve them, but has been unable to do so.

Wednesday evening.—Has passed a very comfortable day, the sickness having entirely ceased; she is quite cheerful, and apparently in a fair way to convalescence.

Three days after this she had quite recovered from the attack, and had daily passed a healthy billious motion; but she continued very weak for some time afterwards.

Case 2.—On Thursday, Sept. 26, 1849, I was summoned early in the morning to visit Mr. John B., a miller's foreman, living about three miles from Reading, who, from the description given me by his wife, appeared to have been suffering from an attack of the epidemic cholera. He had been apparently in the best of health all the day before he was attacked, and up to half-past one in the morning, when he was suddenly, without any previous warning, seized with a most violent pinching pain in his bowels, which, at the moment, he attributed to wind in the abdomen, although he could not recollect having eaten anything which could by any possibility have produced it, nor was he generally subject to any flatulent distension of the bowels. With this there was an urgent desire to go to the water-closet, but he found that he passed but a trifling motion, not relaxed until two o'clock, when he got up, as usual, to attend to the business of the mill. He then found that the exertion of getting out of bed produced a violent and excessive action of the bowels, the first stool or two being of a natural healthy colour, but relaxed in consistence,—the others, which followed, eight or ten in number before I saw him, being composed of a thickish dirty white fluid, similar to gruel, or ground rice, steeped in water; he did not, however, feel any particular sensation of sickness. Following these symptoms there succeeded almost immediately a curious and almost indescribable feeling of faintness and languor, with a general failure of his muscular strength, so that when he attempted to walk about the room he felt as if he should sink into the earth, as he expressed himself. He now felt extremely trembling and cold, the skin, especially of the legs and arms, shortly assumed a pallid appearance becoming deadly cold to the touch, and his limbs were affected with painful and frequently-recurring spasms. His face looked wan and altered from its natural appearance. His wife had put his feet into hot water, which afforded him some, but only temporary, relief; she had also given him some warm brandy and water, which had had no better effect.

As another pressing engagement prevented my seeing him immediately, I directed his wife to use the hot water packing in the manner I have described, and to give him a portion of the following mixture every two hours:—℞. Confect. aromat. ʒss.; olei caryophyll., ♏xx.; sp. armoraciæ comp., ʒii.; aquæ menthæ virid., ℥vj.; M. ft. mist. cap. 4tem partem secundâ quaq. horâ.

At eleven o'clock, a.m., I visited him and found him still wrapped up in the blankets, and in a profuse perspiration over every part of his body. My directions had been fully carried out by his wife, who gave me the following account of his amendment:—Although so deadly cold just before the packing process was commenced, he began, in less than a quarter of an hour, to feel a gentle heat, which, commencing in the abdomen, gradually diffused itself over the extremities, and in less than half an hour his whole body had become bathed in perspiration; encouraging this, he had remained enveloped in the wrappings during the two hours previous to my seeing him, when I found him in the state I have described. What was most remarkable, the cramps, which had been very painful just before the application of the hot packing, ceased on the production of the sweat, and never afterwards returned, and it was observed that the relaxation of the bowels ceased shortly afterwards; the pain of the abdomen was almost gone, only a slight tenderness, on pressure, remaining.

At one o'clock, p.m., he had had but one motion, which he had passed under the bed-clothes, to avoid the exposure to cold; it was of a fæcal character, and had entirely lost the choleraic appearance of those passed in the early part of the morning.

Wednesday (next morning).—I understood from his wife, who thought it unnecessary for me to see the patient again, that he had passed a very comfortable night, having had one or two healthy bilious motions, the pain of the abdomen had ceased, the ordinary heat of the body had returned and remained, and he was thinking of getting up and walking in the garden; but he felt himself extremely weak, and, as he expressed himself, quite knocked down by the suddenness and severity of the attack. I should mention that there was some, but very little, diminution in the quantity of urine secreted during the attack. There was no re-active fever afterwards.

Case 3.—Mr. James D., a newspaper vendor at the Great Western Railway Station, at Reading, was seized, on Wednesday, Sept. 26, 1849, about seven o'clock in the evening, with a most violent and sudden pain in his abdomen and relaxation of the bowels, accompanied by constant sickness and vomiting of a dirty white fluid like gruel. He had been quite well during the day preceding the seizure. I afterwards ascertained that he had been eating a quantity of water-cress some little time before the occurrence of the attack, which had occasioned a sensation of great distension of the abdomen and twisting pains; for this he took some warm brandy and water, which, however, he immediately threw up. The symptoms not subsiding, but, on the contrary, manifestly increasing, I was called to visit him about two o'clock, a.m., on the Thursday morning, seven hours from the date of the attack, when I found his arms and legs drawn up in knots from the most painful spasm, the muscles of the abdomen being similarly affected; his feet and arms were extremely cold, and covered with a moist exudation, but there was a feeling of some degree of warmth over the surface of the abdomen; he had a peculiar sensation at the pit of the stomach, which he said was something like heartburn; but different to anything he had ever experienced before. The pulse was very feeble at the wrist; he complained of excessive thirst. I ordered him to take immediately a quarter of a grain of muriate of morphia in a pill, and to be carefully enveloped in the hot water packing, according to the method described in the account of the preceding cases; I also ordered him to take the mixture as directed in these cases.

In about half an hour his whole body and limbs had become bathed, at first, in a gentle, and afterwards in a profuse perspiration,—so much so, at last, that it ran down his face in streams. He was allowed to remain in this state until about four or five o'clock in the morning, at which time the spasms had entirely ceased, as well as the pain and sickness, which seemed also to have ceased on the occurrence of the perspiration. The blanket packing was then carefully removed.

Thursday (next morning).—Has had no relaxation of the bowels or sickness since the occurrence of the perspiration; there is a gentle warm moisture over his whole body; he feels very weak.

Friday.—Still feeling extremely weak; but his appetite has returned, and he has lost all his uneasy sensations.

Saturday.—He has so far recovered as to be able to resume his usual occupations on the platform of the railway, but is still weak, and looks as if he had been suffering from a long-standing debilitating disease, rather than from an illness which, in its most active state, had run over only a few hours.

I ought to mention, that, on the very day of his seizure, he had got into the occupation of a public-house near the railway, built in an arch over a stinking ditch, which had only a day or two before been cleaned out, much to the annoyance of the neighbouring inhabitants, and the patient himself

---

(a) The following is the method which I adopted in this and the succeeding cases. The sheets and counterpane having been removed, two large and thick blankets were laid one over the other smoothly upon the bed. The patient was then laid upon these blankets, thus disposed, and a flannel pad made of four thicknesses of coarse house-flannel, such as is used in cleansing floors, (the pieces being sewn together round the edges, to prevent their coming apart,) was wrung out of hot water, as hot, indeed, as the patient could bear it, and rapidly laid over the pit of the stomach and upper part of the abdomen. This being done, the blanket nearest the body was carefully but quickly packed round him, one end being brought over his body, and tucked under on the opposite side; the other drawn over in an opposite direction, and likewise tucked under the body on the other side. The second or under blanket was then applied in the same manner, great care being taken so to bring them round the throat, as to confine the heat generated by the process without any unpleasant constriction; the same care was used to enclose the feet; over these a number of other blankets, sometimes as many as nine or ten, or even more, were laid, these being only lightly tucked round the patient. He was allowed to remain covered in this way, until the perspiration appeared upon the face, when the outer coverings were carefully removed. Sometimes it was necessary to apply more than one pad over the abdomen; and in one of the worst cases, where the coldness was excessive, it was necessary to place one on each thigh of the patient. When it ap- [illegible]

[illegible] sweat, a sma[illegible] and placed round the head, immediately relieved the feeling.

had been greatly affected by the stench. No re-active fever followed this attack. There had been some, but no particular diminution in the secretion of the urine, during the most severe period of the disease.

Case 4.—John T., a prisoner in the County Gaol at Reading, generally speaking, a healthy-looking man, was taken ill on Sunday morning, Oct. 14, 1849, with such violent and sudden crampy pains in his abdomen, that for a short time after the attack he was scarcely able to stand up-right. The pain was so agonising and intense, and such strange feelings came over him, that he fainted away, and remained unconscious of where he was for a considerable time afterwards. On his recovery from this state, he was seized with vomiting, and frequent and excessive purging, so that the dejections, which were thin and watery, ran away from him without his being able to restrain them. He had been perfectly well the day before the seizure, and had been at work at the pump, like the rest of the prisoners. Thinking that he was suffering from nothing more than an ordinary bilious attack, he did not apply for medical assistance until the evening, when I found him complaining of extreme cold, his legs and arms covered with a clammy perspiration, and feeling more like the limbs of a corpse than of a living being; he was almost pulseless at the wrists, speaking in a hoarse and almost inarticulate voice, and looked extremely wan and dejected. Having little doubt of the nature of the seisure, I directed the hot packing to be immediately applied, but, owing to some imperfection in the process, it did not entirely answer my expectations, only producing a warmth of the body, without perspiration; it, however, relieved the pain in the abdomen, and in some degree the vomiting, but the purging continued all the night. He had taken a quarter of a grain of muriate of morphia early in the evening, which had been repeated after two hours, and his spine had been rubbed with a strong liniment, containing liq. ammoniæ fort. and tinct. lyttæ., until the skin had become reddened by the friction. He also took a dose or two of astringent medicine during the evening.

Monday, next morning.—The vomiting and pain in the abdomen have ceased, but the diarrhœa, which has assumed a decidedly choleraic character, continues, but not so frequently or profusely as yesterday. He is warm, but not in the least perspiring. He suffers from excessive thirst. During yesterday and to-day he has passed very little water, which is voided only in drops, but the secretion is not entirely suppressed. As the packing had not completely answered its intended purpose, he was again packed up with the hot flannels, and covered with a large number of extra blankets; in about an hour and a half, or two hours, his body and limbs had become bathed in a profuse perspiration, in which he was allowed to remain for several hours. During the whole time, from the very commencement of the attack, there had been an entire suppression of the biliary secretion.

Tuesday.—The supernumerary blankets having been gradually and carefully removed, he has remained in a gentle perspiration ever since the packing; the vomiting has entirely ceased; the pulse, which was scarcely perceptible before, has risen to its natural standard; the secretion of urine has returned; and there is a fæcal appearance in the motions, although they are not so deeply tinged with bile as I could wish. In the latter part of the day he had a slight return of the coldness of the limbs, for which it was considered necessary again to apply the hot packing, which restored the circulation in about twenty minutes. Since that, he gradually improved, and, in the course of two or three days, I found him well enough to be discharged from the Infirmary, suffering only from extreme debility, which appears to be the usual consequence of the disease, when treated in the manner I have described.

Case 5.—I was called up between three and four o'clock on Sunday morning, Oct. 14, to visit Mr. G., storekeeper of the County prison, who was suffering from what appeared to be an attack of the prevailing epidemic. I found that he had been seized all at once about four o'clock on the previous afternoon with the most violent pains in the bowels, more particularly severe just at the pit of the stomach, which was immediately succeeded by cold chills, and a peculiar trembling sensation, such as he had never felt before, over his whole body.

The pain was so severe, that it seemed to occasion a cold sweat all over him; and, although the sweating was very profuse, he still felt remarkably chilly in himself, while it continued; and his skin, particularly that of the arms and legs, was almost icy cold to the touch. He complained of a very unpleasant and unusual sensations of languor, not like common faintness, but as if, as he expressed himself, he should sink down into the bed and die. He had not had any diarrhœa. The secretion of urine was diminished.

He was much in the state I have described when I first saw him; his pulse was feeble and irregular, and his tongue slightly furred: he had been previously fomented with hot flannels, in the ordinary manner of fomentation, but it had failed to afford the slightest relief to the pain.

Thinking he was in a state of partial or commencing collapse, I immediately had him packed up in the manner I have described, and covered with six or eight extra blankets, several of them being doubled, and a hot water bottle was applied to his feet; he had been sick only two or three times during the night before I saw him, what he brought up being of a dirty light colour, like thin arrow root; but he had constantly been tormented with nausea.

It was full four hours before he got into the usual perspiration; and as there was evidently an entire suppression of the biliary secretion, or a retention of it in the gall bladder, he was ordered to take two grains of calomel, half a grain of opium, and quarter a grain of tartar emetic in a pill every hour for three hours.

Simultaneously with the application of the hot packing, a linseed meal poultice, smeared with a liniment, composed of strong liquor ammonia, tinct. lyttæ, and turpentine liniment, was applied over the whole length of the spine, and allowed to remain about an hour, when it was carefully withdrawn without removing the bed clothes.

He was allowed to remain in the perspiration induced by the packing, the heat being, of course, modified by the careful removal of the extra clothes, for several hours; he told me that he did not feel much relief from the perspiration just at first, but the pain gradually subsided; and, at the expiration of about three hours from its occurrence, the secretion of bile had returned, and the matter which he now vomited appeared of an intensely bright green colour, and was voided in considerable quantities. This bilious vomiting continued at intervals during the whole of the Sunday, but the pains had ceased, and his skin continued in a gentle moisture, and quite warm; some small doses of calomel and rhubarb were ordered to act upon the bowels, which had not been moved since the seizure, but they did not produce the desired effect.

Monday (next day.)—Has passed a more comfortable night, although he has been occasionally harassed by the bilious vomiting; he is, however, in all respects, certainly better. He was now lying with only the usual quantity of bed clothes, but remained quite warm; ordered to take an aperient draught, with rhubarb and magnesia, and in the afternoon he had an ordinary bilious motion, when the vomiting of bile completely ceased, and he has not been sick once, the whole of the bile appearing to pass by stool. From this period he gradually recovered, and, on the Friday following, five days from the period of the attack, was so far convalescent as to be able to go out of doors a little; but he felt extremely weak, and continued so for some time afterwards.

My esteemed friend and colleague, Dr. Woodhouse, saw this case several times in consultation with me, and expressed himself much pleased with the effects of the water-packing, in recovering the patient from the state of partial collapse into which he had fallen in the early part of the disease; and, as he had a case of the same kind under treatment at the time, determined to give it a trial the same evening; the notes of this case, taken by Dr. Woodhouse himself, with great care, and which he kindly permits me to publish, are faithfully transcribed in the succeeding case:—

"*Case* 6.—Mrs. ——, aged 24, was seized about eight o'clock on Sunday morning, October 14, 1849, with a sudden and violent vomiting of bilious fluid from the stomach, for which effervescing draughts, opium, creasote, and various other remedies were administered without appearing to have the slightest effect in checking it. Sinapisms and blisters were applied to the epigastrium, but still the distressing vomiting continued. There had been no diarrhœa. She shortly afterwards became extremely cold, with a feeling of great shivering and exhaustion, pulse feeble, and scarcely distinguishable at the wrists; her voice feeble, and altered from its natural tone, and, altogether, she appeared to be approaching the state of extreme collapse. Finding all the above-mentioned means had failed to check the vomiting, and restore re-action, I determined, about half-past eleven at night, as the symptoms were becoming increasingly urgent, to try the effects of the hot-water packing, as described by Mr. Bulley, in the *Medical Times* of August 29 for the treatment of scarlatina.

"The effect of the application was, that she almost instantly fell asleep, and remained in that state for an hour and a half, at the end of which time she complained of a sense of suffocation, and earnestly desired to be liberated from the confinement and heat to which she had been subjected. On removing the wrappings, it was found that her skin had become uniformly warm and moist, and her pulse had risen to its natural fulness; the bilious vomiting had ceased, and from that time she began gradually to recover. Two days afterwards all the symptoms of the disease had disappeared, but she remained extremely feeble. The secretion of urine, which had been suspended for twelve hours previous to the application of the packing, was found to be restored shortly after its discontinuance. On the following Sunday, seven days from the date of the attack, the patient was convalescent."

Remarks.—The foregoing cases have been selected from fourteen similar ones, which have come under my observation during the prevalence of the late epidemic; they have not all of them been altogether such severe instances of the disorder as those which I have related, but they have all been subjected to the same method of treatment, and, with the exception of one which terminated fatally, after twenty-two days' duration, from phrenitis, occasioned by the incautious administration of too much wine by a servant, have all been followed by the same favourable results.

The presumable *modus operandi* of this remedy has been so fully discussed in a recent communication to the *Medical Times*, that it is scarcely necessary to advert to it again; and I would only say, that it appears to act by anticipating the operations of nature to relieve the disease, with the advantage, perhaps, that the hot stage of the natural re-action is shortened, and the sweating, which appears to be the end and object of all natural febrile actions, in sured without any particular distress to the constitution. It would appear also, that, over and above the relief of the internal congestion by the restoration of the cutaneous capillary circulation, which has always followed this method of treatment, something may be due to the elimination of the poison of the disease, or a part of it at least, through the profuse and prolonged perspiration to which the patients have been subjected.

I have been frequently asked, if I thought the method of treatment I have suggested would be applicable to cases of extreme collapse, and I have invariably answered, No; because, considering this state to be a moribund condition, ensuing either through the original intensity of the seizure, or the failure of remedial means, it is no more possible to restore a patient from this condition in this disease, than it is in any other, where the powers of life have been so far subdued as to render recovery impossible; it is only available in cases of moderate

intensity, which might, and probably would, lapse into the state of extreme collapse if left entirely to nature.

It would appear, that, in some of the most severe and protracted cases of this disease, although the circulating functions seem to have been partially or even wholly restored, the system of organic nerves, which have been paralysed by the long-continued congestion to which their ganglionic centres have been subject, does not recover its healthy tone of action, but remains more or less completely paralysed till death; and, in this respect, its condition may be likened to a paralytic limb, ensuing from congestion of the brain, which often remains in that state for a considerable time after the congestion has been removed, and the brain has recovered its healthy function,—with this important difference, however, that, from the sympathetic nervous system being so essentially necessary to the continuance of organic life, the organic functions cannot be maintained while the paralysis continues, and the patient gradually declines from sheer sinking of the vital powers. In such cases as these, which I have read of, but never seen, it has struck me, that electro-galvanism, which, in cases of atonic dyspepsia, arising from a presumable torpor of this system, is often of great service, might be a valuable means of removing, or at least relieving, this paralytic condition.

It will be observed, that very little medicine was administered in the cases I have related; in some of them, the cardiac mixture, with the oil of cloves, given in the early period of the attack, seemed to afford relief; small doses of opium also, at this time, appeared to be of service, on the presumption that the congestion of the ganglionic nervous system was preceded, as is generally the case in other diseases depending on congestion, by irritation, but afterwards, where the congestion was fully established, it seemed to do harm by increasing it; in the majority of the cases, I relied almost entirely on the hot-water treatment, with the general effects of which, as partially illustrated in the foregoing cases, I had every reason to be perfectly satisfied.

If it were possible to observe the natural progress of a case of genuine epidemic cholera which had not been interfered with by any kind of medical treatment whatever, we should be enabled to see how far unassisted nature of itself was capable of overcoming the disease, and we might also be able to form a better judgment as to the extent to which we might reasonably go in the administration of the remedies which in other diseases of an analogous character are found to assist her efforts; taking into consideration that the re-active powers of the system in this disease, display themselves in proportion to the greater or less intensity of the collapse, and *vice versa*, and that, *cæteris paribus*, the re-active fever would most probably be most violent when the preceding collapse had been most severe, and this holds good in regard to several other diseases. It would also seem probable, that a natural recovery from a severe attack of this disease, would mainly depend upon the constitutional powers of the individual attacked, thus a person having a naturally feeble circulation, or suffering from a debilitated habit of body from any cause, might experience a very slight or no reaction at all, from the state of collapse, while a person of greater constitutional vigour, and stronger frame, might be subject to such an amount of it as would prove dangerous, or even fatal in the result; it would therefore appear, that in an extreme case, a strong man and a feeble one would stand much about the same chance of a natural recovery from the disease, the strong man might die from the effects of the excessive re-action, the feeble one from no re-action at all, or at least an imperfect one, and it was this consideration which led me to adopt the remedy which I found so successful in the foregoing cases, and which, I think, would answer in most cases of this disease where the collapse was not extreme, either by its power of encouraging reaction in some cases, (which, when properly applied, it almost invariably appears to do,) or in moderating it in others, which latter it appears to be particularly capable of effecting, by the ready means it offers of regulating the critical perspiration by the gradual removal of the coverings used in the process. In a feeble subject, there is no great fear of an excessive re-action; in this class of cases, the principal care would be, so to moderate the perspiration induced by the process, as that it should not produce an excessive debility, which a little attention to the after management of the induced sweating would prevent.

From all that I am able to understand of the disease, both from what I have seen of it myself, and from what I have gleaned from the observations of others, I have great reason to believe, that internal remedies, whether of a stimulating or anodyne nature, if not administered during that particular phase of the disorder which precedes the state of actual collapse, frequently do more harm than good; but I am also ready to admit, that, in the early stages of the malady, both these classes of medicine are capable of effecting great benefit: thus, in 36 cases of diarrhœa which occurred in the prison during the prevalence of the epidemic, small doses of the muriate of morphia, combined with a carminative, were given in the very commencement of the attack, which seemed to allay the irritation that accompanied the first occurrence of the internal congestion, and assisted in the restoration of the cutaneous capillary circulation, which, in many of them, was beginning to fail; and in this way, with the exception of two which lapsed into a malignant form, the disease quietly subsided.

The same may be said of the beneficial effects of calomel, which, according to the opinion of the most celebrated writers on its therapeutic action, has the power of stimulating the capillary circulation of the liver, and probably that of the system generally; and there is no doubt that in that stage of the disease just preceding the actual collapse, this remedy, by thus stimulating the capillary circulation, may be, and has indeed been proved to be, of the greatest service, by aiding the restoration of the animal heat; but when the stage of collapse has fully arrived—when all the organic functions have become paralyzed—when the assimilative actions of the body are annihilated, through the total inertia of the organic nervous centres—when neither medicines nor food can be turned to their proper account—it stands to reason that internal remedies generally can be of no particular use; on the contrary, they do great harm; for, when indiscriminately given during the period of collapse, they are not (owing to the interruption or suspension of the absorbing functions of the lacteal system), taken into the circulation; but if frequently repeated during this stage, as they often inconsiderately are, they accumulate in quantity, and remain unchanged in the stomach, of course not producing the slightest effect upon the disease, and the patient either sinks in the collapse unrelieved by the remedies, or, on the contrary, if, either through the natural reactive powers of the system, or by the successful application of the ordinary external means, reaction, and consequently the assimilative functions, be only partially restored, then the medicines which have been collecting in the stomach begin to act in their accustomed manner, but, from the quantity accumulated, act excessively, and thus we find, that, even after reaction has been perfectly restored, the patient will die either in a state of stupefaction if opium has thus been administered in excess during the collapse; or, on the other hand, from excessive secondary fever and irritation if calomel has been used in the same manner, and the same theory would hold good of other remedies of the same classes, provided always that the collapse was extreme, and the vomiting had altogether subsided, as is frequently observed in the last stages of the disease.

CHOLERA IN TAUNTON WORKHOUSE.—A Correspondent of the *Times* gives the following classification of 60 persons who have died in the above workhouse, where the cholera has raged with great violence:—Belonging to the Girls'-school, 25; Boys'-school, including the master, 10; male adults, 9; female adults, 9; men above 60 years, 4; women above 60, 2; infants, 1. It appears, from the statement of this Correspondent that a searching investigation is necessary.

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.

OPERATION FOR THE RELIEF OF AN OLD STRICTURE OF THE URETHRA, COMPLICATED WITH A PERINEAL FISTULA.

This operation has been lately performed by Mr. Stanley under the following circumstances. A young man fell upon his perineum about two years ago, and ruptured the urethra. This injury was followed by a stricture, which gradually increased, until in December last the urethra gave way behind it, and occasioned effusion of urine. In this condition the patient first came under our notice in the hospital. He was then treated, as such cases usually are,—that is, an incision was made into the perineum, to afford a temporary passage to the urine. When the immediate effects of the effused urine had passed off, Mr. Stanley set about dilating the stricture. After repeated piercings with the stilette catheter, he succeeded in introducing a large sized gum elastic catheter into the bladder, and then left it there for six days. At the expiration of that time, the catheter was removed. All this, however, was productive of no benefit, for the urine still continued to flow in by far the larger quantity through the wound, and the man left the hospital in very indifferent health, with a bad stricture, and a urinary fistula to boot.

After having spent the summer in the country, our patient returned a few weeks ago to the hospital without the slightest amendment, and anxious to undergo any operation which afforded a chance of relief. On Saturday last Mr. Stanley divided the stricture by an incision in the perineum, and then passed a full-sized catheter through the entire course of the urethra into the bladder. But we will describe this proceeding a little more in detail. The patient is placed in the position for lithotomy. A staff is passed down the urethra to the seat of the stricture, which, in the case before us, was about the bulbous portion. An incision is then made in the middle line of the perineum, and, with the forefinger of his left hand in the wound, the operator guides the knife into the groove at the end of the staff. The next, and by far the most delicate part of the operation, consists in cutting through the whole of the strictured portion of the urethra, so that a female catheter may be passed from the wound through the remaining sound portion of the urethra into the bladder. This done, the staff is withdrawn, and, with a little manipulation, it is easy to pass a full-sized elastic gum catheter through the whole course of the urethra into the bladder. The catheter, of course, must remain in the urethra, until the integrity of the canal is restored.

The above proceeding appears to be a most rational mode of dealing with these otherwise intractable cases of stricture. We might adduce two other instances which Mr. Stanley has recently treated in a similar manner with success. But we will watch the present case to its close, and report the result of it on some future occasion.

REMOVAL OF NECROSED BONE FROM THE INTERNAL CONDYLE OF THE HUMERUS.

William Wheeler, aged 21, the subject of this operation, is now in Bentley Ward, under the care of Mr. Stanley. About two years ago he received a smart blow on the inner condyle of the humerus, from the fist of one of his companions. A swelling subsequently arose on the inner side of the elbow, and gradually increased in size, accompanied with considerable pain. When admitted into the Hospital, about ten weeks ago, the swelling was of the size of a hen's egg, remarkably hard, and painful on pressure; the superincumbent skin was not discoloured, and the movements of the elbow free. Upon the whole, the precise nature of the tumour was at that time doubtful. But the disease soon afterwards became evident; partial suppuration of the swelling took place, the matter was evacuated, and dead bone discovered at the bottom. For some weeks the case was left to nature. Finding, however, that the motion of the elbow joint was likely to be seriously and permanently impaired by the

condensation of the surrounding tissues, Mr. Stanley considered it right to make an attempt to remove the diseased bone. Accordingly, a free incision was made, care being taken not to divide the ulnar nerve. The necrosed bone, which proved to be a portion of the internal condyle, was then removed by the forceps. There was no reason to apprehend that the elbow joint was opened in the operation.

OPERATION FOR THE RELIEF OF A STRANGULATED FEMORAL HERNIA, WITHOUT OPENING THE SAC.

This operation was performed a few days ago by Mr. Wormald. The subject of it is a female, aged 77, now in Lucas Ward. She has had a reducible femoral hernia for twelve years or more, but has never worn a truss. She was brought to the hospital on the 15th Nov. with well-marked symptoms of strangulation of the bowel. Castor oil, a warm bath, an injection of the compound senna mixture, and ice to the tumour, were tried in succession without any benefit. After about forty-eight hours' strangulation, the operation was performed. A perpendicular incision, two inches long, was made on the inner side of the tumour, and the subcutaneous tissue removed so as fairly to expose the hernial sac. A director was then introduced into the femoral ring on the inner side of the sac, and the stricture divided; after which the intestine was returned without any difficulty. The patient has progressed favourably since the operation, and is now doing well.

We would direct attention to an improved kind of director employed by the operator on this occasion—an improvement, we believe, which is one of his own. This director differs from that in common use in being much broader, but with a very much shallower groove. One can easily understand that an instrument of such a form can be introduced beneath a stricture with great facility, and that it has, besides, the great advantage of keeping the neighbouring parts out of the way of the knife during the division of the stricture.

Mr. Lawrence has lately had occasion to operate upon two females with strangulated femoral herniæ. In the one the bowel could be returned without opening the sac; in the other it was necessary to do so, the stricture not being immediately caused by the femoral ring. Both cases are at the present time progressing favourably towards recovery in Queen's Ward.

COMPOUND DISLOCATION OF THE ANKLE.—ATTEMPT MADE TO SAVE THE LIMB.—AMPUTATION AFTER THE TENTH DAY.—DEATH OF THE PATIENT.

Charles Hollis was brought into Kenton ward, and placed under the care of Mr. Stanley on the 30th of October, 1849. He is a man of middle age and very intemperate habits of life. He was standing on the wheel of a cart, when, in consequence of the cart being moved forwards, he fell, and the left foot became entangled between the spokes of the wheel. The injury thereby occasioned was a compound dislocation of the ankle. The skin was torn across nearly half the front, and the whole of the outer side of the joint and the lower end of the fibula protruded through the wound. It was evident, also, that the tibia was dislocated forwards. The anterior tibial artery was exposed, but apparently uninjured. The posterior tibial vessels and nerve were also uninjured. The question of immediate amputation arose. In consideration of the age of the patient and the integrity of the main vessels and nerves of the foot, the question was determined in the negative. Accordingly the dislocation was reduced while the patient was rendered insensible by chloroform, and the limb was placed upon the side.

During the night following the accident, the patient became delirious, unpacked the splints, and caused much additional mischief to his leg, by attempting to get out of bed.

On the third day, inflammation, of an erysipelatous character, commenced in the skin and subcutaneous structures of the leg, accompanied by fever, a furred tongue, a rapid pulse, and great excitement of the nervous system. The inflammation quickly extended to the knee, and so on up the thigh, nearly to the groin. Leeches, in the first instance; and, subsequently, incisions, had no effect in arresting the inflammatory process. The subcutaneous tissues became infiltrated with pus, and large portions of the skin here and there sloughed. With this extensive suppuration and sloughing the strength of the patient began to decline from day to day. His pulse grew more rapid and feeble, his tongue became dry and brown, and his nights were passed without rest. Notwithstanding the efforts which were made to support the sinking powers of the constitution, it was obvious that, under existing circumstances, death was inevitable; accordingly, after consultation with his colleagues, Mr. Stanley amputated the limb, by the circular operation, on the tenth day after the injury. Such was the feeble state of the circulation, that only the femoral artery required a ligature.

During the first few days after the loss of the limb, our patient did certainly appear to rally, and sanguine expectations of his recovery were entertained. But we were disappointed. The skin of the stump sloughed, and no effort was made to throw it off. The digestion gradually failed, till the stomach finally rejected all nourishment, and death ensued on the 11th day after the amputation, and the 21st after the accident.

At the close of this case the question naturally suggests itself, whether, in severe injuries of this nature, happening to individuals who are known to be habitually intemperate, immediate amputation does not give a better chance of life.

The nature of the injury sustained by the ankle-joint was found to be of a very unusual kind. All the ligaments were torn without any fracture. This state of things presented a remarkable contrast to a case of compound fracture amputated about the same time, where both malleoli were found to be fractured, while the ligaments were entire.

[For the history we are indebted to Mr. Harry Thorold.]

COMPOUND FRACTURE OF THE SKULL, UNATTENDED BY A SINGLE SYMPTOM OF INJURY TO THE BRAIN.

We cannot forbear from attracting passing attention to this case, which is still detained in Kenton Ward under the care of Mr. Stanley. It is that of a young man, by name James Sullivan. On the 20th of October last, he was struck on the left parietal bone by a brick, and finding that the scalp was wounded, he walked to the hospital to have his head dressed. The house-surgeon, putting his finger into the wound, discovered that the bone was fractured, and, under the apprehension of more serious results, very properly took the man into the hospital. Up to the present time, however, the case has progressed without a single untoward symptom. No complaint has been made of pain in the head. He sleeps well, and would eat and drink well if he were allowed to do so. Indeed, the man has throughout felt so well, that he cannot understand why he should have been detained in the hospital at all.

PROGRESS OF MEDICAL SCIENCE.

SCOTLAND.

[From our Edinburgh Correspondent.]

The first meeting of our Medico-Chirurgical Society, for the season, took place on Wednesday, the 21st of November, Mr. Syme, the President, in the chair. Instead of an opening address, Mr. Syme gave at once an account of an unusual form of hernia, in which he had operated successfully a few weeks ago. Mr. Syme will doubtless publish a more exact history of this case than could be collected from an oral statement. In the billet the case was set down as an internal hernia. It was not, however, an internal inguinal, that is to say a ventro-inguinal hernia, as that name might suggest, owing to the operation having been performed in the region of the inguinal canal. It was internal in another sense, as not having issued from the abdomen at all. The patient, a corpulent man, about fifty years of age, six months before had become subject to an inguinal hernia of the right side, for which a truss was worn during four months and a half, and then left off, as the disease had entirely disappeared. On the 13th of October, six weeks after the truss had been discontinued, Mr. Sidey was called to see him in the night, and found him suffering under symptoms resembling those of strangulated hernia. At that time Mr. Sidey was able to discover a tumour the size of a hen's egg, in the right iliac region; but the next day, when Mr. Syme saw the patient, there was so much general swelling of the abdomen, that neither he nor Dr. Patrick Newbigging could detect the tumour of the night before, as described by Mr. Sidey. The last gentleman, however, distinctly pointed out its seat, and even thought he could still discover its outline. Mr. Syme, seeing that the case was one of manifest urgency,

Mr. Sidey's known accuracy of obs

mined to operate. An incision was made throughout the whole extent of the inguinal canal, and the superficial epigastric was taken up. No hernia appeared in the canal, but on further dissection, the remaining coverings of the cord being divided, a dark-coloured tumour was seen near the superior aperture. The sac contained intestine, and the stricture was particularly firm. By perseverance, however, the finger nail was first insinuated, and, finally, a probe-pointed bistoury, by which the stricture was divided sufficiently for the return of the hernia. The recovery was complete. Mr. Syme added some observations on the difficulty of determining what was the cause of the stricture in this case. This case appears to belong to those coming properly under the head of internal strangulation, as when the stricture is caused by the presence of some preternatural band or ligament within the abdomen; and if it be properly referred to this head, it stands by itself as having admitted of a cure by operation.

Professor Simpson next made a communication to the Society "on the detection and removal of Intra-Uterine Polypi." The Professor began with remarking on the common idea, that polypous tumours of the cervix and of the body of the uterus, must make their way into the vagina, so as to become accessible for removal before the hæmorrhage, and other ill effects resulting from them, could prove fatal. It appears, that this idea must be received with great limitation. Death has taken place from exhaustion under the sudden expulsion of a uterine polypus, And Dr. Simpson exhibited to the Society a beautiful preparation of the uterus with a large polypus contained entire within its body, taken after death from an unmarried woman, in whom, by exploration through the os and cervix uteri, the existence of the polypus had been ascertained, but which proved fatal, as she refused to submit to any ulterior treatment. His plan of treatment, after the discovery of the presence of polypi in the cervix or in the body of the uterus, is to dilate the parts by means of sponge tents. The tents which he employs are narrow and acuminated, corresponding to the diameter of the os and cervix uteri, and are made by dipping the sponge, not in melted emplastrum ceræ, but by means of a solution of gum arabic, so that the natural moisture of the parts either alone, or assisted by injected fluids, quickly enabled the sponge to dilate. For the small cellular polypi of the cervix, the use of one tent for a few hours commonly suffices; but for the large polypus of the uterine cavity, several tents in succession are requisite. After the dilatation of the parts, the means of removal fall under the same rules as when the polypus penetrates spontaneously into the vagina. A short discussion followed, which turned chiefly on the error occasionally committed of mistaking inversion of the uterus for polypus. Dr. Simpson remarked on the importance of ascertaining the small depth of the uterus in inversion as a diagnostic sign.

There was then read "A Case of Intestinal Calculi," transmitted to the Secretaries, by Mr. Sharp, of Cullen. The patient was a child six years old. Several concretions had been passed, or extracted, which were exhibited; they varied from 4½ to 6½ inches, in their largest circumference. These concretions were plainly composed of fibres derived

from the coverings of the oat contained in oat-meal. In the conversation which followed Drs. D. Maclagan and Bennett referred to the papers which had been formerly read before the Society on the concretion from the oat. Dr. Maclagan ascribed the diminution of the disease in those districts of Scotland where oatmeal constitutes the chief part of the food of the population, to the more perfect winnowing of the meal. Dr. Bennett reminded the Society of the felting and adhesive property of the fibrous matter of the oat-grain, as pointed out by Dr. Carmichael, of Buckie, and of the artificial concretions which that gentleman had sent to the Society the summer before last. Dr. Carmichael's statement is so remarkable that we think it worth while to transcribe it:—"This substance, (the hairy covering of the oat-grain,) when separated from the meal, is generally termed oat-dust, and is possessed of a remarkable felting property, superior, perhaps, to that of wool. This may be seen at any time in any oatmeal mill, where, by the rotatory or oscillatory motion of the harp, or wire-cloth sieve, that separates it from the grain, the dust shows a decided tendency to form into soft bulbs, and if anything suitable for a nucleus, such as a thread, or any other adherent matter occurs in its way, it will gather round it in layers, and thereby form masses of considerable size. This is more particularly the case, if the mass be occasionally wetted; for it seems the felting property of this, as well as that of wool, is increased by watery fluids." Dr. Carmichael also remarks, that oil destroys the felting property, and thus, such concretions are not likely to form when a sufficiency of oleaginous or animal food is taken along with an oatmeal diet. Professor Goodsir remarked, that peculiar arches in the form of the colon were probably connected with the formation of concretions from oatmeal, as the horse, in which the colon cells were so largely developed, was particularly liable to concretions.

Under the head of Medical News, Dr. William Gairdner gave an account of the use of chloroform, as he had lately seen it administered in some of the London hospitals. The several speakers who took part in the subsequent discussion expressed their continued faith in the safety and efficacy of chloroform. In general, however, the use of the inhaler, practised in London, was considered as less safe than the handkerchief, as advised by Dr. Simpson. Some circumstances were mentioned as indicating extreme carelessness in the mode of its administration in several hospitals. Mr. Syme took credit to himself for having been opposed to etherisation, but as to chloroform, he said, he considered its extensive and almost daily use in the Edinburgh Infirmary for so long a period, without a single accident, as conclusive in its favour, when used in a state of purity and in a proper manner. He considered the half-and-half mode of using it as excessively injurious. As there was, he said, a decided prejudice against the employment of this agent in surgical operations, in which it was so eminently advantageous, it had become necessary that those associations of medical men which, like the majority of this Society, were satisfied of its safety, should exert their influence to overcome that prejudice. Dr. Simpson said, that much of the chloroform employed in London was still imperfect, being made by pyroxylic spirit instead of alcohol, but that he understood Messrs. Duncan and Flockart, of Edinburgh, had lately received large orders from London for the pure chloroform, which they manufactured, by the use of which he anticipated a more favourable impression would be made in London as to the freedom of this kind of anæsthesia from inconvenience and danger. He went on to say, that chloroform had been charged with giving an unusual tendency to puerperal mania. In answer to this statement, he would refer to the case of a lady attended by Dr. Ebenezer Skae. This lady, on her first delivery, had become affected with puerperal mania without the use of any anæsthetic agent, while chloroform had been freely used in her second delivery without any such tendency. He proceeded to ask Dr. David Skae, superintendent of the Lunatic Asylum at Morningside, who was present, if he had met with many cases of puerperal mania that could be ascribed to chloroform. Dr. Skae answered, that of the cases of puerperal mania admitted into the asylum during the last two years, none had been subjected to chloroform during labour. Dr. Simpson then noticed a case, to show how readily unmerited blame might be cast on chloroform for ill effects following, though not caused by its use. A lady had a small fibrous tumour on the mamma, which she consented to have removed; and, on being asked, declined to be subjected to chloroform during the operation. When, however, Mr. Syme arrived the next day to operate, she thought she would like to have chloroform, but, none being at hand, the small operation was performed without it; yet the following night she was seized with severe symptoms, among which were considerable delirium, which, without doubt, would have been ascribed to chloroform, had it been employed. Mr. Syme added a case, in which he had recently taken up the subclavian without chloroform, where, the night after the operation, violent symptoms came on, along with delirium, which, in like manner, would have been ascribed to chloroform if that agent had been used.

SELECTIONS FROM FOREIGN JOURNALS.

TREATMENT OF ANEURISM BY ELECTRO-PUNCTURE.

A Memoir was lately read at the Academy of Medicine, on this subject, by M. Abeille. The aneurism was in the left subclavicular region. The subject of it was an old woman about 67 years The swelling between the scaleni was considered to be aneurismatic by a number of medical gentlemen, and by the reporter, from the annexed unequivocal symptoms:—A pulsating tumour, rising and falling, but sinchronous in systole, and diastole with the pulsation of the heart; partial diminution of the bulk of the tumour, by compression of the artery near the heart, while the pulsations in it cease; and conversely increased tension of it on compressing the axillary artery; *bruit de soufflet* evident, perceptible by the ear applied to the tumour, and produced probably by the friction of the current of blood on the layers of coagula in the sac; sensation of trembling communicated to the hand; anomalous character of the subclavian, which, arising from a trunk common to the primitive carotid, rises in an arch above the clavicle, so as then to run between the scaleni. The proof positive that the subclavian is the seat of the disease is demonstrated by pressure on the tumour being immediately succeeded by the cessation of the axillary and radial pulse.

The operation was performed on the 10th Feb., 1847, and the battery was charged with water, saturated with a mixture of the sulphuric and acetic acids. The battery consisted of twenty zinc and copper plates, ten centimetres in breadth, with four steel needles, from two to two and a half inches, covered to within a line of the head and point with mastic.

The patient was placed in the horizontal posture, with her head towards the right, being previously narcotized by ether. The needles were introduced in pairs, without crossing, about three-fourths of an inch, it being ascertained, from the absence of resistance, that they were in the sac. The electricity was strong, the sparks fine. The operation continued thirty-seven minutes. Every five minutes the poles were brought in contact with the opposite pair.

The patient awoke in about a minute; pain very severe, exclamations, agitation, convulsive movements of all the corpus, and especially of the left arm. In five minutes time the tumour began to become hard, resisting, tense; ceased to beat, and the pulse, like a thread, almost imperceptible. In thirty-seven minutes the needles were removed; two of them requiring a slight rotatory movement, leaving small superficial eschars, having a little suppuration at a later period.

The subclavian was partly compressed below the tumour by the thumb during the operation; and for ten hours afterwards, by means of a cushion having a kilogramme attached to it.

After the operation, the tumour was hard, without impulse or beating; bruit de soufflet gone, which had been heard in the sac previous to the operation. In twenty-four hours, the radial pulse had ceased to beat, the left arm became swollen and cold, and it was requisite to apply bags of warm sand. No pulse; rigidity during nearly forty-eight hours. The pulse returned, as the heat of the limb was recovered. On the third and fourth day from the operation, two bleedings from the arm were practised in consequence of cerebral congestion.

From the fourth day after the operation, the tumour began to diminish, On the tenth day this was distinctly palpable; and on the eighteenth day it was only half the original size.

For several days it became stationary, and then it declined gradually and slowly. The thirty-seventh day, no swelling observable; sensation of an oval body, situated deep, flattened, hard, in the position of the tumour. Three months after, there was still some appearance of this hard body, and the pulse was weaker in one arm than in the other. At that period, the artery above had increased somewhat in magnitude, and three secondary trunks were observed arising from it, which had not been previously noticed, which we presume to have been the vertebral, the inferior thyroid, and the posterior scapular.

At present, two years and a-half since the operation, the artery presents the same appearance, having gained no increase in bulk; and there is still to be felt in the position of the original tumour a dense resisting body; though a certain amount of pressure by the finger is requisite to make it be felt. Its size is not so great as formerly was noticed.

As to the advantages of the operation, M. Abeille concludes with these observations:—

"The pain produced by the electro-puncture seem not to be measured by any other kind of pain. This reason seems to him sufficiently strong for employing, by preference, the ligature in every instance where it can be put in practice, as in aneurisms situated on the extremities. The dangers of the electro-puncture, the inconveniencies, if not accidents which it may occasion, are equivalent, if they do not exceed, those of the ligature; hæmorrhages, supposing the operation be not successful, cauterisation of the skin, and of the walls of the sac, subsequent suppuration, and dangerous hæmorhages. Were it less painful than the ligature, it may be tried, resorting to the latter, should it fail. As, however, it neither diminishes pain nor danger, it can never rival the ligature in aneurisms of the extremities."

In conclusion, then, electro-puncture may be of immense advantage in certain exceptional cases, despite the severity of the pains which attend on it. It is the only *merit* it can claim. It would, however, be unequalled, if it were proved, by a number of facts, and by pathological researches, that the employment of it was invariably followed by the coagulation of the blood.

TRIBE OF THE GHILANES (LORD MONBODDO'S ORIGINAL MAN.)

M. du Courey, traveller in Africa and Asia, has lately read before the French Academy an extract from his travels, referring to the tribe of the Ghilanes, a breed intermediate in character between man and the monkey family, living in Central Africa, (South Soudan.) The following are his notes made on this tribe, from what he had learned from the Arabian Djelabs and Nubian, and from what he himself had witnessed in the person of one of the natives:—

The Ghilanes constitute a peculiar race, as they have a great resemblance to the monkey.

Shorter than the other negroes, their height rarely exceeds five feet. Their proportions are generally unharmonious. The body is weak, and appears feeble. The arms long and thin. The hands and feet longer and broader than in other tribes; the lower jaw strong and much elongated; their cheeks prominent; the forehead short, and strongly directed backwards; the ears long and shapeless; the eyes small, black, brilliant, and exceedingly mobile. The nose large and flat; the mouth large, armed with acute teeth, powerful and exceedingly white; the

lips thick and large; the hair curly, but not very woolly, not thick, short. But in this they are specially distinguished, that the vertebral column is continued externally and inferiorly, so that both males and females possess a tail from two to three inches in length.

EMPLOYMENT OF NEURONISM IN CHOLERA.

By Dr. WAGENINGE.

We require here to draw a broad distinction between the theoretical and practical portion of the paper. The first embracing observations on the nature of the cholera, sufficient to justify the Author in treating the affection by neuronism, or animal magnetism. The second refers to the practical results procured by that plan.

The theoretical portion is that which more particularly demands attention. The Author, in fact, engaging in a question very much agitated altogether recently in Belgium, the subject of the primary pathological elements of the cholera shows with tolerable precision, that the first appreciable morbid action of the malady is not the coagulation of the blood. To the reasons we have already had occasion to urge against that proposition, he subjoins others, the most conclusive of which, without question, is the following. "If," he observes, "the blood had been first affected, and not the solar plexus and the sympathetic and pneumogastric nerves, the first morbid symptom must have been in the heart and in the lungs, (anxiety, palpitation, and syncope,) and not in connexion with the stomach and intestines, (vomiting and diarrhœa)." As may readily conceived, it is in the nervous system of ganglions that the Author places the first pathological change made on the system by the efficient cause of the cholera. But though we suppose that to be a satisfactory reason for subjecting the cholera patient to the magnetic treatment,—and though it were admitted that the magnetism is successful, because it is tonic and stimulant,—we have our doubts, notwithstanding the different remarks the Author has brought forward in support of his views. With this object in view, and to come to the practical point of the matter, we shall satisfy ourselves in extracting the only passage which bears on the magnetic treatment in the general Report of the Commission appointed by Government to examine the subject of the treatment of the cholera. The Author would observe, and in that we concur with him, that it is not decidedly unfavourable to *neuronism*:—

"We have only once," observes the Report, "seen animal magnetism employed on the person of a negro who experienced most violent cramps in the extremities; and, though a general remission of the parts spasmodically affected followed the application, it was but of temporary duration: in this way, that when the manipulation was practised on the lower extremities, the spasms were renewed in the upper, (the same appears to have taken place in one of the cases reported by M. Wageninge). The patient died a few hours after. Though we have not seen that the application of animal magnetism has been attended with a permanent relief of the disease, its action has sufficiently proved, in this most desperate case, its efficiency in relieving the cramps, so as to be deserving the attention of medical men at the outset of the disease."—*Ann. de la Soc. Med. et Chirurg. de Bruges.*

APPOINTMENT OF SURGEON TO THE QUEEN'S PRISON.—We have much pleasure in stating that the Secretary of State has been pleased to appoint Mr. R. L. Hooper, of the London-road, Southwark, to be Surgeon of the Queen's Prison, (vacant by the lamented death of Mr. Thomas Morton,) notwithstanding the great interest made by upwards of fifty candidates of the highest professional reputation. This must be considered an act of justice rendered to a gentleman who has performed nearly all the medical duties of the Prison for the last twenty years, and, at the same time, it reflects the highest credit upon Sir George Grey for his impartiality and discrimination. The office of Assistant-Surgeon to this prison (so long held by Mr. Hooper) is now abolished, and such an appointment would never have been necessary if the Surgeon had not resided so far from his duties.

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post office Orders should be made payable to the Publishers WM. S. ORR AND CO.

THE MEDICAL TIMES.

SATURDAY, DECEMBER 1, 1849.

IN the two Articles on our Sanitary Laws, we endeavoured to indicate briefly those crying social evils which surround the home of the poor man in our large towns, which encompass him with the agents of disease, and pollute both his physical and moral health. Whether these evils are ancient or modern; whether they have always existed or have lately arisen; whether, as asserted by some, they have diminished with our progress, or, on the contrary, have grown with our growth; whether they are peculiar to this phase of society, or are common to all periods of history, is a matter which we need not stop further to examine. Enough for us that they *do* exist, and are in opposition alike to all natural laws, and to the letter and spirit of those Divine rules to which this nation claims to pay peculiar homage.

Nor is it necessary, that in these pages the evidence of the existence of such evils should be given. We need not analyse the Reports of the Registrar-General, of the Inquirers into the Health of Towns, of Mr. Chadwick or of Mr. Simon. Enough for us that *our* readers are unhappily but too well acquainted with the condition of that class, to succour whom, the lives of so many of our Profession have been nobly sacrificed. Enough for us, that if any one doubt our statements, the path of inquiry is open to him; and if, after considering fairly the condition of our large towns, he puts not manfully his shoulder to the wheel, and demands not with us justice to the poor man, we will hold him as Dives, who, clad in Tyrian purple and in fine linen from the looms of Syria, saw without a sigh of compassion the neglected Lazarus dying at his feet.

It appears that now, with a willing Legislature and a sympathising public, we have commenced our Sanitary Reform—we are about to wipe off the neglect of ages. We are about to say to our labouring class, "here is an atmosphere no longer tainted with the elements of disease; here is abundant water, no longer corrupted with the refuse of decay; here are dwellings into which the light of heaven can unobstructed pass; now we give you health, so long a stranger to your homes, and many years of vigorous life, of which you and your fathers have been recklessly deprived. And, after this, we will give you possessions of still greater worth: household comfort, which has been but a visionary dream; decency, which has heretofore refused to dwell in your miserable homes; and moral health and virtue, which can exist only with their types and outward signs, health, cleanliness, and personal respect."

If our Sanitary Reformers can make these promises good, we will decree them statues of gold in the market-place, as the ancients honoured their heroes and demigods. Their names, familiar in our mouths as household words, shall be engraved in our records as those of men who have done the State good service. Conquerors, shall they be called, in a war more terrible than the conflict of men; soldiers, in a cause holier than the love of country and homestead. God's priests will they be, casting out the devils from the defiled body of the land, and making clean the temple, in which pure spirits should alone and unmolested dwell.

But, in order that this great work may not fail, or, at least in our generation, be shorn of its fruits, our Sanitary Reformers must recognise both the nobility and the gravity of their task. Let them receive, in good part, the advice we are about to offer them, as coming from those who are desirous only of giving true and faithful aid in this national purification.

And first, in all humility, we would venture to say, in so great a work, let no private motives of personal advancement or power sully those efforts which should be freely rendered to the cause for its own sake, and without more than that just recompense which men for their labour openly and fairly claim. Ill will fare the cause which has only to support it, the exertions prompted by a selfish spirit, or an ambitious and worldly design.

We would say, in the next place, know well what it is you want to do. Is it not to provide better air, better water, better dwellings, and, if possible, more wholesome food for the poor man? Is it not to see how unhealthy occupations can be best remedied; sickness be best obviated; the natural infirmities of man most easily removed? If so, you have no child's play before you; you have work which it will take more than a generation to do. Perform this work in such a manner, that your successors will not have to pull down the fabric you have commenced to rear, as insufficient and unsafe. And, in order to do so, consider first what it is which has permitted thoughtless and avaricious landlords to crowd helpless tenants into dwellings infinitely worse than those which a fox-hunter provides for his hounds; which has allowed a monopoly to Water Companies for profit, and has cared less for the poor who cannot complain, than the herdsman leading his steers to the fresh waters, cares for his dumb beasts; which has permitted men to be poisoned with effluvia from excretions which the merest rustic removes from his unreasoning cattle. Is it not the utter neglect of superintendence which has permitted such evils; a want of foresight, so extreme, that the most obvious consequences have not presented themselves; so great a dread of interfering with property, which is a mere human possession, that it regarded as nothing the sacrifice of life, which is God's own gift? Has not everything connected with our poor been permitted to proceed unnoticed and unchecked, although it is abundantly manifest, that if there be any duty of Government which is peculiarly sacred, it is this—to see that while property has its rights, it does not ignore its duties, and does not sacrifice for its own benefit the claims of those whom it knows cannot appeal against it!

But as an illustration makes an argument clearer than a volume of description, let us take

a case which at this moment occurs to us, and which is as simple and unsurrounded with difficulty as any of these cases can be, where public good opposes property.

During the prevalence of the late terrible disease which passed over our land, a singular exception to the general sickness was given by the town of Birmingham. The inhabitants of Birmingham rejoice greatly that neither in 1832 nor in 1848 did the cholera carry death and mourning into their streets. There are not wanting those who gave public thanks to the Supreme Ruler for his preserving and saving care. Well, when the cholera returns, in 1864, or whenever its next mysterious circuit may be, Birmingham will have no cause to rejoice. The Destroyer will not pass over it again without marking some doors with the sign of death. And for this reason—Birmingham is built on ground which is high, and allows natural drainage; its sewers run up no hills; its refuse fluids percolate and purify themselves in a sandy stratum which extends under nearly the whole town. The houses are, for the most part, without cellars, and, though often miserably dirty, are comparatively dry. No putrid drains nor stagnant waters give to the poison of cholera its local conditions of increase. Such is Birmingham now. Twenty years hence, will have arisen by its side another and a very different town. Close by the great railway station, on a tract of low marshy ground, watered by the river Rea, a tributary of the Trent, a new town for labourers is rapidly rising. Streets are laid out, and rows of houses are in course of formation. No pains have been taken to drain this low and unhealthy site; the floors of the cottages will be saturated with the water of the moist soil. Apparently, no sewers will be made, so the exhalations of cesspools will soon be added to the native malaria of the place. In less than twenty years there will be a large town at this spot. It will have been built in all the hurry, and with all the imperfections, of commercial speculation thinking only of its profit. Twenty years hence, our Sanitary Reformers will be reckoning what excess of mortality is yearly caused by this insalubrious site, and to what exact extent its moisture and its low level have augmented the third epidemic of Cholera.

Now here is a case of the simplest kind. Ordinary superintendence, and ordinary precautions will neutralise all these dangers. We would say to the Board of Health, your first duty is to prevent an accession to those remediable evils which, even now, annually destroy 30,000 persons in England alone. See that these landlords in Birmingham drain their ground, make their site healthy, build their streets so that air may pass along them, provide water for the poorest inmate, construct sewers which shall really be of use. If the Board reply that such superintendence and cautious interference is not in their power, we answer, demand then, the power from Government, and, if it be not granted, surrender the vain attempt to perform duties which it is impossible you can, without such power, worthily discharge.

The code of the Sanitary Reformers should be summed up in these three words: Recognition—Prevention—Removal. First, they should know well what it is they have to do; secondly, they should see that, henceforth, no additions are made to the overwhelming evils they discover; thirdly, they should determine the means by which, in course of time,—not in one year, nor in ten years, but by the unremitted exertions, it may be, of several generations,—the evils which have been permitted to grow up among us may be mitigated or removed.

We took occasion to remark, in our last Article, that the present mode of the administration of the Health Act leads us to doubt greatly whether the removal of existing evils will be accomplished by its means. We shall not return to this subject; but shall, in our next Number, give our own conception of the method in which the Government should attempt to solve this knotty problem. We claim for ourselves no originality, and no infallibility; we probe merely this social disease with such strength as has been given to us, and determine, to the best of our knowledge, what are its means of cure.

APPOINTMENTS AT UNIVERSITY COLLEGE.

We have already announced that the Professorships of Medical Jurisprudence and of Materia Medica at University College, vacant by the decease of Dr. Thompson, have been filled up by the appointments of Dr. Carpenter and Dr. Garrod. It is impossible that the College could have made selections which will be more approved of. Dr. Carpenter possesses an European and Transatlantic reputation, which has been well earned by the most unremitting exertions of abilities of the highest order, in the promotion and advancement of many branches of medical science. He has paid special attention to Medical Jurisprudence and Hygiene, and will do ample justice to a subject which is acquiring daily more important and practical applications. Dr. Garrod, also, is one of those from whom the medical public justly expect great additions to our knowledge of medicine. The researches in which he has been hitherto engaged have already yielded most interesting and valuable results, and have stamped Dr. Garrod's name as that of an excellent and industrious observer. University College has now filled up its numerous vacancies well and usefully, and we may venture to prophesy that this important Medical School will continue its admirable system of tuition as vigorously and as successfully as ever.

THE GENERAL MEDICAL ANNUITY SOCIETY.

The General Meeting of this Society took place on Monday evening, at the Hanover-square Rooms; and, as we consider that the objects of the meeting are of great importance to the interests of the Profession, we have given a report of the proceedings in another part of the Journal. There can be no doubt that Medical Practitioners in the provinces (for the Metropolis is to a great extent cared for) are in want of a Provident Society that shall afford to themselves, when disabled, and to their widows and orphans, a sufficient annuity to place them above the sore exigencies of sudden and unlooked-for destitution, on the payment of an annual premium, which, while proved ample to give security to the Society, shall not be so large as to deter the less fortunate Members of the Profession,—and for that reason the more requiring its benefits,—from subscribing to its funds. We have, for many years, maintained the necessity of such an Institution; our hearts are cordially engaged in its advocacy, and have ardently hoped for its realization, and we have trusted that the irregular struggles that have been recently made to attain this philanthropic object would gradually acquire method and consistency, and establish some ground of success.

It is well known that the plan of the Society, originally proposed by that excellent man Mr. Daniell, was so imperfect in its construction and Rules, as to be quite useless for its intended objects, and a Committee of the members of the Society was appointed some time since, to ascertain what modification of the Rules was necessary, in order to give the plan working capabilities. About the same period, a Mr. Hawtayne,—who, by the way, is neither a medical man, nor an actuary, nor, judging by his page of "Proposals," even a passable grammarian,—started a new project, imitative of the general plan of some dozens of other Societies already in existence. The Sub-Committee of the Annuity Society, it appears, have adopted and recommended this plan of Mr. Hawtayne's, under the limitation, however, of confining it within the circle of the Profession. The meeting on Tuesday evening was convened, to consider the propriety of abolishing the Society established by Mr. Daniell, both in its principles and plan, and instituting another, upon the principles of ordinary Annuity Societies, giving power, at the same time, to a Provisional Committee to spend all the funds subscribed, given, and bequeathed to the former Society, having specific principles, though a bad plan, for the purpose of organising a new Society altogether distinct and different in its basis and plan of operation.

A most interesting discussion took place, as might have been expected, upon this highly important question. Mr. Ross, in an argumentative speech, entered into an analysis of the statements and inferences contained in the Report of the Sub-Committee, and urged by them as pointing out capital defects in Mr. Daniell's scheme. He showed that the Report contained numerous inaccuracies and misstatements, which were, of course, unintentional, but which destroyed the validity of every argument in the Report, contending against the feasibility of Mr. Daniell's principles. As the Sub-Committee did not attempt to rebut any one of the points brought under their notice by Mr. Ross, we must presume that these errors and misrepresentations were indefensible. As this is a question that affects the vital interests of every member of the Profession, it cannot be settled, and ought not to be prejudged, by a blind appeal to the opinion of this authority or the other, but must depend upon the correctness of its propositions and the truthfulness of its proceedings for confidence and success. Another such Report would ruin the Society.

Assuming that it will be attempted to carry out the Society upon the new plan, time will

show, after the tables have been published,—for it can hardly be expected that men will be induced to join a Society without any tables of premiums being placed before them for approval,—whether this scheme will meet the wants of that large proportion of the Profession whom we most ardently seek to benefit. If it do not, we shall regret the lost opportunity most profoundly; if it do, none will rejoice more warmly than ourselves. At any rate, the want we have indicated exists; and when there is an evident mission, there will be also a man in due season The mass of the Profession must be moved before any plan of the kind can beget any hope of success; a general meeting of a dozen gentlemen, however well disposed, high-minded, and philanthropic, will not, we fear, effectuate any great results.

The Committee, however, should constantly keep in view the responsibility of their functions and the sacred character of their trust, and place the Society under the management of men of untainted repute; for if, by any chance, it should lapse into the hands of mere adventurers, their attempts will end in failure, more sad and prejudicial to the interests of the Profession than if an effort had never been made.

PROFESSOR OWEN AND THE SMITHFIELD COMMISSION.

The prospects of City Sanitary Reform are rather cheering at the present moment,—a Royal Commission having just been issued to inquire into the whole subject of "the live and dead meat" markets of London. The members of the Commission are,—Mr. G. Cornewall Lewis, M.P., (chairman,) Hon. Frederick Byng, Sir Henry Verney, Bart., M.P., Sir James Duke, Bart., M.P., Mr. William Miles, M.P., Professor Richard Owen, Mr. John Wood, (Common Councilman of Aldersgate Without); names which should assure the public, that the subject will be thoroughly investigated. We feel especial satisfaction in noticing the appointment of Professor Owen. His exalted intellect, and thorough knowledge of the subject of hygiene, render him eminently qualified for the post which he is called to occupy; and the Government has only discharged its duty, at once to science and civilization, by appointing this gentleman to take part in one of the most important investigations relating to the sanitary condition of the City of London. We entirely agree with our Contemporary, the daily *Times*, "that a more capable and unprejudiced man could not be found."

The Cholera at Eyemouth.—In this village, within the last twenty-four days, no less than 54 persons have died of cholera and fever, being at the rate of 4 per cent. of the population, which numbers about 1,400. On some days the number of deaths was as many as 8. Business of every kind has been totally paralyzed since the outbreak of the epidemic.

The Cholera and the Sanitary Movement.—We announced some time since an outbreak of the cholera in Taunton-street workhouse. In connexion with this fact we take from a local paper the following description of the *scale*:—"The Union workhouse has been built near the end of East Reach, in the lowest part of the town, where the deficiency of drainage and nauseous accumulation of sewerage at the back of the building have been the subject of complaint." These houses would be properly designated as "Institutions for the more speedy getting rid of the poor."

PUBLIC HYGIENE.

DRAINAGE; AS IT AFFECTS THE HEALTH, WEALTH, AND MORALITY OF SOCIETY.

No. I.

Comparative Insensibility of all Classes to the habitual Nuisances around them.—Languid Government and Parochial Efforts on the recent Visitation of Cholera.—Comparative State of the Public Mind on Preservation and Destruction.—Actual Present Condition of Main Sewers in Aristocratic and Wealthy Localities.

Certainly the influences of the mind upon the body are very wonderful, and in no respect more remarkable than in the extraordinary extent to which they can deaden any one or more of the external senses, or reduce this sense to a kind of passive endurance in the very face of its activity which one might naturally have anticipated would have risen in rebellion, and asserted its rights in some way or other. This may appear a paradox and contradiction in terms; but it is not the less an every-day fact. We know of no instances and demonstrations that can be stronger than those which instantly present themselves on the subject of bad drainage, and offensive effluvia from drains and sewers. Formerly, scarcely anybody ever noticed the stench from the gully-holes and gratings in the public streets. We never heard a word on the subject. But *now* the stench is in everybody's nose—the complaint in everybody's mouth. How is this? The same fact has existed for years,—probably for centuries,—and men's noses were as capable at that time of their natural action as at present; yet how few were those, if any, who ever noticed the abomination; and as to complaint, if it had been uttered aloud, the individual would surely have been regarded as a very eccentric person indeed, and the parish authorities would have smiled him down as one who was far "more nice than wise." The plain fact is, we never smelt the stench till we were told of it. And we have never smelt it in its full force till very lately, after having been told again and again that it was very bad, and very injurious,—that foul stenches could breed fevers, and that people had actually died in consequence. We have, therefore, at last, come to perceive, that these effluvia are very abominable nuisances, and that they ought to be abated.

Seeing, then, that the public is at length awake, and becoming, almost daily, more and more alive to the dangers which constantly threaten them at a few yards, perhaps inches, beneath their feet, and in the atmosphere all round them, the next question that presents itself is, how far the Government, (which so seldom leads, but which generally follows public opinion promptly, if not very energetically,) has been moved by the pressure from without, and what amount of energy, judgment, and good effect, has attended its measures and resulted from its efforts.

We cannot give a more statistical, accurate, and comprehensively condensed portraiture of the amount of Government and parochial efforts in sanitary matters, than is presented by the following extract, which refers to one of the most fatal weeks of mortality during the recent period of cholera, for the departure of which we have but now been offering up a General Thanksgiving. The writer incidentally, but most strikingly, alludes to the comparative amount of effort displayed in the discovery and apprehension of the two murderers who have just expiated their crime as a public spectacle:—

"In the week ending Saturday, August 25th, (says the masterly compiler of the Report of the Registrar-General,) the deaths in London were 2,456; of which 1,272 were by cholera, and 240 by diarrhœa.

"The energy with which parts of our institutions work, makes the defects of the rest more evident. On August the 9th last, a man was murdered in Bermondsey, and before his death, reported by the Coroner, will appear in these returns, one, and it is possible both the persons charged with the murder, will be in custody. Steam-ships, the electric telegraph, the heads of the police, and professional agents, specially chosen, were all employed to arrest *the destroyers of this one life*; the columns of the newspapers were filled with the details of his death. On the same day, a stockbroker died at No. 12, Albion-terrace, Wandsworth-road; a widow lady and an old domestic servant at No. 6; &c. &c."

The Report then goes on to particularise *nineteen* deaths in the same street, at the houses contiguous to Nos. 12, 13, within a very few days of each other, all of cholera. The Report then proceeds as follows:—

At No. 13, (inhabited by Mr. Biddle,) where the first death occurred, and where two deaths were afterwards registered, the refuse of the house had been allowed to accumulate in one of the vaults, which is a very large one, for about two years, and when removed, last week, the stench was almost intolerable, there being about *two feet of wet soil covered with maggots*. The drains also had burst; overflowed into the tank, and impregnated the water with which the houses were supplied. On the back ground was an open ditch, into which nearly the whole of the soil of Clapham runs. As turpentine to flame, so is the exhalation of such cellars, tanks, and sewers, to cholera. It broke out and diffused itself rapidly; it attacked many; and nineteen inhabitants after some hours of suffering, sickness, and spasms, expired."

"The effects of decomposing refuse and water on health were well known; their fatal subsidies to cholera had been heard of every day; yet no steps had been taken for their removal from Albion-terrace in July; no medical police had interfered to disturb the contents of Mr. Biddle's cellar; and now the nineteen masters, servants, parents, children, rest in their graves, it appears to be taken for granted that blame attaches to nobody—to nothing! Not to the householders themselves—to the guardians of the district—to the institutions of the country!"

The cause of this extraordinary disparity of effort is not far to seek, and is manifestly attributable to the present condition of education, and to what the author of "Orion" designates as the "diseased drama" of the trial, sentence, and execution of "murder heroes," compared with which, the philosophy of cleanliness and longevity seems but a dull consideration. Something, also, must be allowed for the construction of the human mind, in any case, which derives more excitement from destruction than from preservation, and is much more alive to the influence of imagination, of whatever colour, than the slow processes of reason.

Against facts like these,—added to a "hardness of hearing" in the Government,—the exhortations and efforts of Mr. Chadwick and Dr. Southwood Smith, though backed by the special powers of the Board of Health, have hitherto lost more than half their force.

But, however deficient in that "diseased drama" of *killing* interest which so attracts and rivets public attention, (not reckoning the recent melancholy death of the five men in Kenilworth-street sewer as of sufficient interest to the unthinking many,) we have yet to see how far the upper and middle classes—more especially the former—will remain insensible and indifferent when they become aware, as they shortly must, of the actual dangers directly beneath their feet. They are rapidly becoming aware that foul effluvia can cause death;—what will they say to the chances which constantly threaten them of a bodily *descent into the sewers*? This may happen any day to man or woman—to part or the whole of a house—to a carriage and horses—to half a street!

The proofs of the above statements are to be found in the reports of the "Subterranean Survey" now going on, by order of the Metropolitan Commis-

sioners of Sewers. As these reports have not yet been published, we are unable to give any extracts from them. The following statements, however, may be depended upon as substantially correct.

It appears that three several parties, of about half-a-dozen men in each, have been for some time actively engaged in the perilous and important office of a subterranean survey of the metropolitan sewers. Of this horrid work each party has generally completed a mile and a-half per week. In this way as many as *four hundred miles* of the sewers have already been surveyed. 200 still remain to complete the map of these dark regions—we had almost called them "infernal regions;" but it will be far more wise to designate them as the *safety-streets* of the health and life of the more sightly streets above.

The quantity of deposit—often of the most offensive and poisonous description—which lies at the bottom of many of the sewers, sometimes amounts to the extraordinary depth of three, and even four feet, and upwards. This is the case in the fashionable regions of Belgrave-square, and Eaton-square; in Spring-gardens, in Whitehall, &c. The amount of deposit in the different sewers so varies, that in order to render the spirit-level available under all circumstances, the surveyor is obliged to have three sets of legs to his instrument. Some times the deposit does not exceed five or six inches; on other occasions, as in some of the sewers in the Surrey and Kent districts, it amounts to as much as five feet, and emitting a poisonous effluvia.

Of the actual present condition of the sewers, it may be instructive to give a few specific examples.

In Belgrave-square, the sewers have a putrid deposit of above a foot deep. In Lowndes-place, the deposit is nearly two feet deep; the drains of the houses half choked up, and the effluvia quite dreadful. The same may be said of Robert's-mews and Belgrave-mews; while the brickwork of the sewers beneath Chapel-street, Belgrave-square, is in a broken condition, which renders it liable to fall in. The same danger exists with regard to the sewer beneath Grosvenor-place, the walls of which, for several hundred feet, are crushed; while the arch, being in some places without support, there is no security for its standing a single hour. This danger more especially exists at the end near St. George's Hospital. The sewer is almost in the same condition beneath Upper Eaton-street, Grosvenor street West. In Whitehall-place, the sewer is very much dilapidated, and the foul deposit amounting to two, and in some places three feet in depth. The sewer walls are liable to fall in, at many points beneath Queen Anne-street and Welbeck-street: and the same danger exists along upwards of *a thousand feet* of sewerage beneath Upper and Lower Berkeley-street and one side of Portman square,—in fact, similar dangers exist in regard to the north, south, and west sides of Portman-square. And so we may say of parts of Cavendish-square and Bryanston-square; so of Curzon-street; so of Harley-street; and so of Westmoreland-street and Woodstock-street, where the whole length of sewer may fall in, at any hour. Duke-street, Westminster, is scarcely any better; neither is Parliament-street,—the arch of the sewer being very often without any support for several successive feet, while the deposit is deep, and of the worst description. A part of the Admiralty sewerage is in an equally dilapidated and dangerous condition, &c., &c.

We could multiply examples, but enough has been said to display the perils to which we are constantly exposed from the condition of the sewers, the worst degrees of which are manifestly beneath the dwellings of the upper classes. The decay of the sewers beneath the houses of the rich, in especial, is easily accounted for. Being out of sight, they are not constructed of stronger materials than the sewers of humbler localities; yet it is obvious that they often have much more work to do.

It will hence be very intelligible, that the duties of the men engaged, either in surveying or cleansing the sewers, is a "service of danger." Converse with any of them, and you hear of half-suffocations, and faintings, and men dragged out on their backs through two feet deep of black slush, and burnings of the face and hands, and frizzling up of the hair, with other "hair-breadth 'scapes in the imminent deadly breach."

It may be asked,—touching the Kenilworth-street sewer, in which the five unfortunate men have just perished,—"Was not the condition of this sewer known? Certainly it was; but as so very many are known to be in as bad, or a worse condition, the authorities, of all kinds, did not see reason for giving it a particular attention.

REPORTS OF SOCIETIES.

GENERAL MEDICAL ANNUITY OR RELIEF FUND SOCIETY.

A general meeting of the subscribers to this Institution was convened on Monday evening last, at the Hanover-square Rooms, for the purpose of dealing with certain resolutions founded upon an elaborate Report which had been prepared by a Sub Committee, and forwarded to the members. This Sub-Committee having taken the various matters brought before them into consideration, came to the following conclusions:—

That an annual subscription of a guinea, or a fixed sum of any reasonable amount, (the plan on which the Society had hitherto been based) can never fulfil the primary design of the Society,—furnish a permanent provision for disabled members, their widows and orphans.—That a Provident Fund, such as Mr. Daniell contemplated, can only be made secure by payments graduated according to the fixed laws of statistics, and the exact calculations of a competent actuary.—That a plan based upon sound and safe principles, and adequate to the proposed end, can alone be expected to obtain support and countenance from the Medical Profession.—That the great majority of the Profession are capable of securing for themselves, their widows and orphans, a provision against poverty, or an augmentation of the means they may be able to bequeath, through the medium of the contemplated Association. That the best policy is to provide a superannuation fund strictly provident, or even deferred annuities for those who prefer that plan, and also annuities for widows and orphans altogether irrespective of their circumstances, so as to embrace both the rich and the less successful practitioner, whilst a Relief Fund may be properly united and worked in connexion with such an Annuity Society. If it should be alleged that this is a mere Insurance Society, the Sub-Committee would observe, that a Provident Society must needs be so; but this, which they contemplate, being strictly mutual, confined to our own Profession, contemplating contingencies which other ordinary societies do not admit, and in connexion with a fund to be applied at the discretion of the Society to relieve its members under every possible form of difficulty or misfortune, would stand alone, in comprehensiveness and usefulness, and would constitute a bond of union for every branch of the Profession and all its members, not hitherto existing in any Institution.

Dr. Forbes was unanimously voted to the chair, and, in opening the business of the meeting, observed, that none who were acquainted with the Medical Profession would hesitate to opine, that such an Institution, upon whose interests they were then met, was much wanted. During the last forty years he had seen countless instances of distress and privation, which might have been prevented if such an Institution had been provided; and he thought it was but little to the credit of the Profession, that such a scheme had not been before entered upon. He was aware that, to a certain extent, the Profession was not a rich one; but he thought that there was a very small proportion of them who could not afford to put something by for their own good. He then adduced the example of the Governess's Institution, where a body of individuals, with far lower means than those of Medical men, had subscribed for the securing Government Deferred Annuities to the number of 400 or 500 in five years; the sum of money thus passing through the hands of the managers in that period having been 52,000*l*. Now, he would say, that if the poor governesses could, in five years, subscribe to this extent, what might not the members of the Medical Profession do. The fact was, their backwardness in supporting themselves by this means arose from too luxurious habits generally; but he thought they had no business with such luxuries, if, as a consequence, they were ultimately to leave themselves dependent on others in their old age.

Mr. Moore then moved, and Mr. Palmer seconded, the reception of the Report which had been presented, which passed *nem. con.*

Mr. Daniell moved the following resolution:—

"That as every subscriber has been furnished with a copy of the Report of the Committee appointed at the last General Meeting, and invited to express his opinion of the same, and as the Manager had received 70 replies approving, and 2 disapproving thereof, this General Meeting, convened according to the laws relating to such institutions, has the power to deal with the Society and the funds belonging thereto, at its pleasure."

Mr. Daniell entered into an account of the manner and the reasons why he had taken up the subject in the year 1844, having originally proposed it, as a member and in connexion with the Provincial Medical and Surgical Association, to form a Benevolent Fund. He had long had his doubts as to the scheme answering as a general plan; but connected with the Provincial Association, as he had at first contemplated, he had no doubt it would have succeeded. His original plan, however, had been affected by a late Act of Parliament, which prevented the enrolment of a Society partly benevolent and partly co-operative; and under these circumstances he thought it right at once to come to London, and lay the case before a majority of the members, and he now asked for both a Provident and a Benevolent Fund. He had received 76 letters in answer to inquiries, coinciding with his own views, and only two objections, out of about 200 subscribers.

Mr. Palmer seconded the resolution, which was then put and carried.

The third resolution was moved by Mr. Tucker, seconded by Dr. Cooper, and is as follows:—

"That the present meeting deeming the recommendation of the Committee worthy the adoption of the Society, and the plan imbodied in the Report deserving the support of the whole Profession, totally rescinds all the regulations hitherto in force."

Before this resolution was put,

Mr. Ross objected to the principles on which it was proposed to abolish the old Society. As to the Provident Fund for superannuated members, apart from the fund for widows and orphans, he still believed that Mr. Daniell's plan was fully equal to all its purposes. Supposing members to become superannuated at 60, he could prove, that from 45 to 100 years of age, supposing the members of the Profession to join in due proportion, you would get not more than 1 in 3 at 60 years of age. Now, he would ask, how many men, above 60, of frugal habits, have less than 75*l*. a year? Say 1 in 5; and even then you could afford nearly 17*l*. a year on that preposterous calculation. In the Commercial Assurance Society, he found, that for a certain annuity they require only 12*l*. 10*s*.; the proposed Society adopted for the same age 33*l*.; hence it might be argued, that 4 per cent. would become claimants; and he believed, with Mr. Daniell, that 3 per cent. was more than would claim on the fund. He thought, therefore, that a guinea subscription would be sufficient, and could not believe it necessary to graduate that amount. He did not see why the young man should pay 10s., and the old man 5*l*.; and he thought that the principle should be not to tax the old man. He objected to the 'Widows' and Orphans' scheme. In Mutual Society it was well-known that a large fund was a burden. What metropolitan member of limited means would be

prepared to give you ten guineas, when he could obtain the same advantage in the Widows and Orphans' Fund for two? He wished a Society to be established, in which, on payment of a low premium, a member's wife or child should be entitled to an annuity only when they had an income below a certain amount. He preferred a contingent annuity, with a small premium, to meet the exigencies of the less fortunate members of the Profession.

Mr. Headland thought that as the purpose of the present meeting was to form a Provisional Committee, Mr. Ross might make his suggestions to that body when it met.

The following resolutions were then passed:—

"That henceforth the Society shall be designated 'The National Medical Annuity and Relief Fund,' and that every member of the Profession in any of its departments shall be eligible to become a member by subscribing to either of its objects, in conformity with its laws.

"That all the monies in the hands of the Treasurer, Manager, Secretary, or other officer, shall, as soon as convenient, be paid over to the Treasurers appointed by the Provisional Committee.

"That this meeting considers that the exertions of Mr. Daniell, the projector and manager of this Society, are worthy of its highest eulogium—most honourable to himself and beneficial to the Profession, and, therefore, would record its cordial thanks and gratitude to that gentleman.

And also a resolution appointing the Provisional Committee.

The meeting then resolved itself into Committee and some preliminary business was despatched.

WESTMINSTER MEDICAL SOCIETY.

Nov. 17, 1849.

F. Hird, Esq., President, in the Chair.

PHTHISIS IN AN INFANT—RUPTURE OF THE CALCANEO-SCAPHOID LIGAMENT—SPERMATORRHŒA—CHRONIC SKIN DISEASES.

Dr. Rogers exhibited the lungs of an infant, about three or four months old. They were studded with tubercles. The infant had perished from tubercular meningitis. When born it was apparently a healthy boy, but soon exhibited indications of tubercular disease in the brain, with violent spasmodic cough and slight bronchial rhonchus. These were relieved by medicine, and the child improved; but after time it was perceived to be affected with strabismus and there was also a muco-purulent discharge from the conjunctiva. A slight cough was also noticed from time to time. The chest sounded clear on percussion, the respiration natural, with the exception of a slight rhonchus; pulse 120. Leeches and blisters were applied, and small doses of hydrarg. cum cretâ were given for the head affection which continued to increase. Shortly before death the cornea of one eye became dull and ulcerated and the aqueous humour escaped. Convulsions preceded by coma, occurred a few hours before death. The *post mortem* examination showed venous congestion of the right hemisphere, two ounces of serum in the ventricles, and purulent deposit at the base of the brain; the optic thalami and the lining of the ventricles were pulpy and diffluent. The lungs were full of tubercles, and the bronchial glands were enlarged and tubercular. The mesenteric glands were in the same state. His reason for bringing the case before the Society was, the very early age at which such extensive tubercular disease had been developed, the ulceration and rupture of the cornea, and the rapidity with which the disease ran its course.

Mr. Nunn exhibited a drawing of an injured foot; the principal peculiarity being a marked flatness of the sole. A country lad, while carrying a pail, had slipped and injured it; was treated for two months without benefit, then came under Mr. Nunn's care. The arch of the foot had fallen; no fracture could be detected; there was great thickening of the parts, and intense pain on pressure; could not stand on the foot. Continuous frictions, and kneading, (q. shampooing,) succeeded in effecting a cure. After the lapse of a fortnight he could put his foot to the ground, and at the end of a month, he returned to his work. Mr. Nunn considered that the calcaneo-scaphoid ligament had been ruptured, with a partial dislocation of the astragalus downwards. Instead of the fat in which the nerves of the part usually lay, he thought they had been imbedded in a firm deposit of lymph, the result of the consecutive inflammation, so that pressure on the part caused the severe pain complained of. The cure was effected by the shampooing acting upon deep-seated vessels, and exciting them to absorption of the effused lymph. The foot was still flat, and would probably remain so.

Mr. Smith brought before the meeting an instrument, made by Matthews, of Portugal street, for applying solutions of argenti nitras to the urethra in cases of gonorrhœa and spermatorrhœa. It consisted of a common catheter, with a stylet, at the end of which there was a piece of soft sponge about two inches in length, imbedded in a sort of bulb which, when used, was soaked in the solution, the instrument passed, and the stylet projected, so that the sponge came in contact with the diseased part of the urethra. By means of a screw at the end of the stylet, it can be turned gently round, so as to apply it to all sides of the canal. He believed this instrument would supersede Lallemand's porte caustique, (a) to which he thought it preferable. He referred to a bad case of spermatorrhœa, under the care of a friend, a very excellent surgeon, who applied the caustic to the urethra by means of Lallemand's instrument. Troublesome bleeding followed for a week, and was succeeded by a bad stricture. The instrument must be used very gently, or it will give great pain. It was not adapted for use in cases where there was a stricture in the spongy part of the urethra, as in retracting the stylet, the stricture might be caused to bleed, and great mischief done. He used the argenti nitras in solution, from ten to twenty grains to the ounce of water.

Mr. Hunt read a paper, entitled,—

SUGGESTIONS TOWARDS SIMPLIFYING THE DIAGNOSIS AND TREATMENT OF CHRONIC DISEASES OF THE SKIN.

He stated his conviction that the difficulty often experienced in the management of these diseases did not arise so much from their inveterate nature, as from the erroneous views so commonly entertained of their pathology. He undertook to prove, that the pathology of these diseases was not determined by the form of eruption, and that, therefore, treatment founded on this kind of diagnosis must be fallacious. That both the syphilitic and the peculiar constitutional lesion which the author denominated cutaneous cachexia, might alike originate the scaly, pustular, vesicular, and other forms of eruption, so similar to each other respectively, that it was impossible to diagnose them by their appearance alone; that there was manifested in each of these two classes of cases a disorder of the general system, which disorder rather than the eruption itself, should become the subject of diagnosis and treatment; that, consequently, the treatment by local applications was not founded on a right principle; and, though it might repel an eruption for a time, it could not destroy it. This local treatment was, therefore, described as only applicable to eruptions excited by causes from without,—as contagion, heat, cold, friction, dust, dirt, vermin, &c. So far as internal treatment is concerned the author proceeded to speak of the importance of distinguishing syphilitic from non-syphilitic cases which he considered could only be done by learning the history of the preceding symptoms; not by the shade of the eruption, nor by the evidence of primary infection, which was often wanting or obscure. He then proceeded to describe the treatment required from the various incidental circumstances complicating skin disease, which demand prior attention before treating the skin itself; such as pyrexia, anemia, disordered functions of the viscera, organic disease, the alternating or revulsionary forms of cutaneous irritation; &c. &c. And, lastly, he described the treatment he had found successful in those cases of simple skin disease in which the viscera were, to all appearance, sound, and the health unimpaired. This was described as consisting in the administration of arsenic in gradually decreasing doses, and always on a full stomach; the dose being regulated by the condition of the conjunctiva, reducing it when this membrane becomes inflamed to any degree of severity, yet persevering with such doses as will suffice to keep it slightly tender, until the disease is cured. The maximum dose exhibited by Mr. Hunt was five minims of Fowler's solution three times a day. Other medicines were mentioned as useful adjuncts to arsenic, under peculiar circumstances and in peculiar constitutions, such as cathartics and Plummer's pill in plethoric subjects, tonics in asthenic cases, tar in sluggish habits, cod-liver oil in strumous subjects, &c. The greatest caution was advised in the use of arsenic, not only on account of the poisonous properties of the mineral, but also on account of its cumulative action in the system, and the therapeutical difficulties arising from the administration of an over-dose; which often excited such an intolerance of arsenic in the system as to render it ineligible for a long period afterwards. The effects of medicinal doses of arsenic were graphically and minutely described by the author, who portrayed its action in four different degrees; the first being that of a tonic, the second affecting the mucous membranes and skin, the third exciting increased exhalation of the serous membranes, the fourth the well-known poisonous effects. The two first degrees were shown to be consistent with the salutary and therapeutic effects of the mineral, the third injurious and dangerous, the fourth destructive. The therapeutic action of the mineral was stated to reside only in doses too small to be mischievous,—larger doses proving not only injurious to the system, but tending to aggravate the cutaneous disease, which is curable by reduced doses. In the course of his paper, Mr. Hunt took occasion to observe, that there are certain forms of revulsionary cutaneous disease, alternating for a time with other disorders, in which a modification of the hydropathic treatment had been found useful. He condemned the quackery of hydropathists, and especially their books, which he described as gross attempts to mislead the public by abusing all medical science; but yet expressed his opinion, that water, when discreetly used, was an important agent in the treatment of disease, and it was desirable that more attention should be paid by the profession to the various modes of applying it;—treatment not the less important because it had been misrepresented and abused.

Mr. I. B. Brown, after speaking in terms of great commendation of Mr. Hunt's practice in cutaneous diseases, detailed the particulars of a case of psoriasis, occurring in an old gentleman, 66 years of age. The disease had already continued two years in the acute form. There were deep fissures, in addition to the ordinary scales of psoriasis, and great pain on flexing the fingers, or on handling anything. The irritation produced by the disease had led to considerable ill health. He gave five minims of Fowler's solution of arsenic three times a day, each dose to be taken immediately after a meal. Redness of the conjunctiva was speedily produced, and soon afterwards the same condition of the fauces, uvula, and tonsils, followed, with irritative cough. This state was removed by a diminution of the remedy, and, after some persistence in the medication, the disease showed manifest appearance of improvement, and the hands were capable of some degree of flexion. At the end of three months, the hands were quite free from disease, and the general health restored. A slight relapse occurred six months afterwards, but was soon cured by the same remedy. He (Mr. Brown) had found arsenic very beneficial in many cases of skin disease in children, and also in many anomalous eruptions, and he thought the profession were much indebted to Mr. Hunt for drawing their attention to this practical fact.

Mr. Chippendale did not consider the practice of exhibiting the solution of arsenic at meal times as at all novel. Dr. Elliotson used to recommend it in his lectures in 1833, 34. He did not know whether it originated with him.(a) He (Mr. Chippen-

(a) The instrument of Mr. Smith's differs from Lallemand's porte caustique only in having a piece of sponge for the solution of nitrate of silver, while the other has a cavity in the stylet for the solid salt itself. It is not, consequently, an invention, and it may be fairly doubted whether it is even an improvement.—Rep.

(a) The practice of giving arsenic at meal-times is anything but novel. We have ourselves used the plan for upwards of twenty years; and we were acquainted with a surgeon whose practice dates back to 1800, and who always gave it at those times. The reason for doing so is explained in the course of the discussion.—Rep.

dale), had found sarsaparilla very useful in some diseases of the skin, and he thought that a combination of arsenic with sarsaparilla would be serviceable, and more successful than if arsenic were given alone.

Mr. Clarke said, that the mode of giving arsenic recommended by Dr. Elliotson differed greatly from that of Mr. Hunt, inasmuch as the former exhibited the medicine in five minim doses, gradually increased, as long as the patient could bear it; and he thought that no danger could accrue, unless certain results, which he enumerated, were produced, in which case the arsenical medication was suddenly stopped. Now, Mr. Hunt also gave the five minim doses, but he ensured the toleration of the drug by diminishing the dose gradually, and was thus enabled to effect cures when others failed.

Dr. Murphy felt much obliged to Mr. Hunt for pointing out the general principles of the management of skin diseases, and drawing attention to their constitutional origin. He was pleased with the allusion to the hydropathic treatment, which, in some instances, was of service. The eczema of the scalp in infants was better treated by cold water and general attention to the digestive functions, than by any other plan.

Mr. Hird considered an important question arose as to the comparative utility of arsenic alone, or in combination with iodine and mercury. He had found in some cases that Donovan's solution would effect a cure, when arsenic alone had previously failed. He agreed with Mr. Clarke that the mode in which the arsenic was given formed the principal feature in Mr. Hunt's practice. He had used arsenic internally for more than twenty years, but had not paid the same attention to its exhibition that Mr. Hunt had done.

Dr. Garrod inquired the nature of the cachectic condition on which some of the cutaneous affections depended, and what was the *modus operandi* of arsenic in the cure of these diseases?

Dr. Lankester had given up the use of arsenic until he had read Mr. Hunt's work; it had produced such bad effects. He thought the giving arsenic at meal times a most valuable hint; it would enable us to continue its use until the disease was cured. He alluded to the case of a lad, 12 years old, who had an eczematous eruption over the whole body. He gave three drops of arsenical solution three times a day at meal times; the disease was cured in three months. He had also had two or three cases of psoriasis, which were cured in a similar manner: in one instance the disease reappeared, but soon yielded to a resumption of the remedy. In another case, eczema of the ear, various kinds of treatment had been tried without advantage: it was cured in two months by the arseniate of potash.

Dr. Snow was not aware who first recommended that arsenic should be given at meal time, but he had always so exhibited it; and thought it was the rule in the profession. He had used it with advantage in skin diseases and in periodical neuralgia, in the dose of seven minims and a half for a man, and five for a female. He never saw any harm from such doses, and had always found it relieve the neuralgia more quickly than quinine. The long persistence in the medication he considered to be an important point in Mr. Hunt's practice, which he was enabled to secure by keeping to one dose.

Dr. Daniell, of Bath, stated, that when he was physician to the Bath Hospital for Cutaneous Diseases, he had cured cases of lepra and pityriasis by thermal baths, and other external applications, after the functional disorders had been ascertained, and removed by appropriate treatment. Skin diseases could be cured by external medicines. He had used arsenic in small doses, and had always ordered it to be taken on a full stomach. He had seen it fail, and Donovan's solution effect a cure. He had no doubt that some skin diseases depended on an inflammation of the dermis, which should be looked to; in many cases they were caused by functional derangement. Bleeding was of service occasionally, and the blood, when drawn, gave evidence of inflammatory action.

Dr. Sibson considered that Mr. Hunt had developed some original views. His classification of skin diseases was very valuable, in subdividing them them into syphilitic, cachectic, and scrofulous; and his rules for medication were very clear. He had shown us a method by which arsenic and other mineral drugs might be given for a long period of time with benefit. If given for a long while, arsenic may be said to be accumulative in its nature; that is, the effects it caused were accumulative, not the drug itself. This distinction he looked upon as important. The medicines said to be accumulative, did not remain in the system, but the effects they produced continued, and, being constantly added to by other doses, became ultimately very alarming. In exhibiting iron, one of these medicines, it would not do to continue it always at the same doses. In the treatment of children, his plan was to give it for two days, then omit it for two, resume it for two more, and again omit for two; by acting thus, he was enable to administer it for a long time, which he could not do under a continuous plan of treatment. The treatment of squamous diseases by arsenic was very old; five minim doses were the usual mode of giving it, but it was not the custom to lessen the dose, but to stop its exhibition altogether when it was doing harm. This, therefore, was a new plan of treatment. The combination of other medicines with arsenic required consideration; in many cases advantage would be derived from the combined effects of arsenic, iodine, and mercury; he, however, should not like to use a formula, but to be able to vary the relative proportion of the drugs as the case might require. This could not be done with Donovan's preparation.

Dr. Ryan stated, that he recollected that it was the custom, fifteen or sixteen years ago, to give arsenic after meals, and the reason was, to prevent the gastric irritation it would otherwise cause. He had known it cure many cases of hemicrania. It might, in fact, be looked upon as a specific in such cases.

Dr. Routh said, that Dr. Garrod had inquired respecting the influence of arsenic in cutaneous diseases. Some years ago he had instituted a series of experiments to determine the connexion between those complaints and the diseases affecting internal organs. In three or four cases, he had found the kidneys affected, not with actual nephritis or Bright's disease, but there was an actual diminution of the solid matters in the urine, amounting to nearly one half. These experiments were carried on for a week, and were not affected by diet. This ineffective condition of the kidneys was cured by strong diuretics. With reference to the use of arsenic in syphilitic eruptions, which Mr. Hunt opposed, as he did that of mercury in strumous eruptions, in the Parisian hospitals arsenic was given in combination with mercury in some stages of syphilitic skin diseases with great benefit. Much had been said of the danger of large doses; he (Dr. Routh) was not aware of any such danger; he had repeatedly given as much as forty drops of Fowler's solution, three times day. No evil effects had resulted, except, perhaps, a trifling headache. The dose of the iodide of arsenic is reported to be one-twelfth of a grain; he had given it in half-grain doses, with no other ill effect than as in the previous instance. On one occasion, however, he had seen a case which apparently supported Mr. Hunt's opinion. A man, who had been cured by small doses of arsenic, had a bottle of the solution given him, to continue his ordinary dose for a while, as he was going out of town. Anxious to get well rapidly, he increased the dose, and took twenty drops at a time; the consequence was, the disease returned, and has remained incurable ever since. He (Dr. Routh) had given arsenic in between two and three hundred cases.

Mr. Hunt accepted Dr. Routh's explanation of the cause of disease in the cachectic instances of eruptions of the skin. He was himself unaware of this condition of the kidneys in such cases; but thought it very probable, and it should be inquired into. He had referred such diseases to a deficiency in the blood, and it was on that account that he ordered the arsenic to be taken at meals, in order that it might be mixed at once with the circulating fluid, and also to avoid gastric irritation. He had not claimed the originality of that practice, nor did he know who first recommended it. At a meeting of the members of the Provincial Medical Association, when the question was mooted, it was found that two-thirds gave it on a full stomach, and one-third when that viscus was empty. Elliotson's mode of giving arsenic was different to that which he recommended, inasmuch as instead of diminishing the dose, he increased it; and when bad symptoms arose, he gave it up altogether. Those cases only were amenable to sarsaparilla, which had a syphilitic origin, or might be called pseudo-syphilitic. Idiopathic cases of skin disease were not benefited by it. He had not tried iodine in any form in skin diseases. In irritable subjects small doses of arsenic were required; in those who were more obtuse to impressions, larger doses were necessary. The amount of the dose did not depend on the size of the patient, but on his nervous susceptibility. To show the extent to which the arsenical medication may be carried, he stated that in a bad case of lupus, arsenic was given, and at the end of the first year the disease was somewhat lessened; after the second, it was still spreading, but the pain was gone; and at the end of the third, the remedies were left off. Three months passed away, and, the disease returning, the remedy was resumed; the patient took arsenic altogether for about five years. He was now well. He then narrated a case in which a lady, by mistake, took forty drops three times a day; she became very ill in consequence, and could not resume it, even in very small doses, until twenty months had elapsed. A cure was effected with difficulty. That large doses were ever taken with impunity must depend, he thought, on the adulteration of the arsenic. It was often mixed with sulphate of lime, so that the Fowler's solution was rendered of much less strength than it should have. It has been sometimes only one-third its proper strength; but such, he added, is not the case now. Arsenic given medicinally seldom does harm; but that affords no reason why it should be pushed to too large doses, when the disease can be cured by much smaller ones.

CORRESPONDENCE.

MR. ROSS AND THE LANCET.

[To the Editor of the Medical Times.]

Sir,—Will you do me the favour to insert the enclosed copy of a letter forwarded this week to the Editor of the *Lancet*:—

I am, Sir, your most obedient servant,
George Ross.

(Copy.)

To the Editor of the *Lancet*.

Sir,—As you have done me the honour to mention my name in connexion with the proceedings of the "Conference Meeting" held at the Hanover-square Rooms on Tuesday, the 20th November inst., it may be agreeable to you to hear a few particulars respecting the convening of that Conference Meeting, although you may not, probably, deem it expedient to give your readers the benefit of my communication. You may do as you like, however, in this matter, for I may probably enlighten them myself through some other channel less likely to miscarry.

The meeting of the 20th inst. was convened by *public advertisement*, and also by *private circular*. The advertisements appeared *twice* in the *Provincial Medical and Surgical Journal*, *twice* in the *Medical Gazette*, and *twice* in the *Medical Times*. They had, therefore, been before the public, previously to the meeting, for three weeks at the least.

The advertisement was not sent to the *Lancet*, it being considered unnecessary to do so, owing to a very general opinion prevailing that it would be of little use, and that it would hardly be worth the cost of insertion; for the other journals being almost universally read by the Profession, it would look very like throwing the money away.

So much for the advertisement not appearing in the *Lancet*.

Circular letters of invitation were also sent to all the leading medical Reformers who represented public bodies, as well as to many individuals who had interested themselves in the question of Medical Reform.

By these means, and in consideration of the objects for which the Conference was convened, a very nu-

merous and influential meeting was obtained; an

, differ

plishec

dious

represented as extreme and irreconcileable, an which, in his truthful and elegant compositions, h has striven to foment and aggravate, were discoverec to be more imaginary than real; and it was provec in the most satisfactory manner that the Medica Profession was far more of one mind, and possessec much more of true gentlemanly feeling and forbearance than could have been supposed to exist, whe so much paper and print had been expended to mak it appear otherwise.

I have the honour to remain, Sir,
Your most obedient humble servant,
GEORGE ROSS.

24, Farringdon-street, City,
November 27, 1849.

THE APPLICATION OF CREASOTE TO BURNS.

[To the Editor of the Medical Times.]

SIR,—Having been a witness of the success attending the application of creasote to burns, firs used by Dr. Stewart in the Queen's Hospital, Birmingham, I submit the following as its *modus operandi*.

The good effects of creasote when applied to a burn are as follow:—

1st. It quickly relieves the pain.

2nd. It excludes the air.

3rdly. The parts to which creosote is applied hav less tendency to slough.

1st. Relief of pain. The *modus operandi* of creasote in relieving the pain, seems to depend on the stimulating properties which the oil possesses; and its action in this respect is best seen in burns of the first division, viz.:—Those producing mere redness. A heated body being applied to a part, excites a greater flow of blood, the vessels become distended, thereby weakened, and congestion is the result. Pain, as in congestion from other causes, takes place as necessary consequence, partly owing to distension of the vessels, partly to the pressure thereby produced on the small nervous filaments The creasote, by stimulating the vessels to contraction, relieves the distension, thereby the pain. Also, the oil applied to the tongue or any sensitive organ, produces a burning pain; in short, acts as a stimulant by exciting a greater afflux of blood to the part, and thus, in a burned portion, the blood before stagnated is carried forward by the force.

2nd. It excludes the air, and it does this in two two ways. 1st. By hardening the cuticle. 2nd. By its power of coagulating albumen.

This effect is best seen in burns of the second class —those producing vesication. A blister being formed, and the cuticle raised from the cutis sera, creasote is applied, which, by drying on it, renders the detached portion hard and horny; therefore better calculated to withstand external impressions.

The serum which is found beneath the cuticle contains a large proportion of albumen. The albumen is coagulated by the creasote, and a tenacious viscid layer is formed on the surface of the cutis sera, highly impervious to the transmission of the oxygen of the air.

3rd. The parts to which creasote is applied have less tendency to slough.

And this occurs partly from the congestion being quickly relieved before the parts have become inevitably diseased, partly from the non-admission of the air, and partly may be attributed to the antiseptic power which creasote is well known to possess.

I am, Sir, your obedient servant,
W. J. MOORE, M.R.C.S., Resident Officer.
Queen's Hospital, Birmingham, Nov. 24, 1849

HEALTH OF LONDON DURING THE WEEK ENDING NOV. 24.

The total deaths registered up to Saturday last numbered 892 in the metropolitan districts, being under the weekly average of five previous autumns by 270, 129 of this number being the "less" of deaths occurring under the head Zymotic Diseases than the average. It is gratifying to find that from the week ending October 13, the deaths have decreased on the average of five years, and in a period of seven weeks, by no less a number than 1629, though our gratification at such a result, while it evidences the abatement of cholera, must be somewhat qualified when we reflect, that such a diminution of deaths must be attributed in some measure to the fact of the cholera having smitten those who would, in all human probability, have been the victims of those diseases which appear to have so sensibly declined. In the period of six weeks, from Oct. 20 to Nov. 24, Zymotic Diseases have been under the average by 524, being nearly a third of the total decrease under all causes. From Typhus, in the last week there were only 34 deaths, a smaller number than has been recorded for a long period. The mortality from Small Pox, however, which has recently been low, suddenly rose from 6 deaths in the previous week to 17 in the last. The deaths from Diarrhœa are now 7 below the average; and only 2 deaths from cholera are registered,—1 in Charing-cross Hospital, from St. Martin-in-the-Fields, and 1 in Blandford Mews, Marylebone.

The mean temperature of the air was below the average of 7 years, during the last 5 days, except on Friday, when it was higher by 1·0; the result for the whole week is a minus on 7 years' average of 0·2. The reading of the barometer at the beginning of the week was 30·18; it decreased to 29·88 in. by the 19th at 9h. a.m.; increased to 30·02 in. by the 20th at 9h. a.m.; decreased to 29·21 in. by 3h. p.m. on the 24th, after which the reading increased slightly till the end of the week. The prevailing wind was N.E.

The Registrar-General has annexed to the Week's Return, Tables of 18,166 deaths from Cholera and Diarrhœa in London, distinguishing sex, and giving the various ages at which they have occurred, with the annual rate of mortality derived from the deaths and population at each age. From this it appears, that the mortality from these causes was uniformly greater among males than females up to the age of 30 or 35; that between 35 and 45 years, females suffered more; that in the decennial period following, the rate of mortality was nearly equal to both sexes; and that up to 85 it was greater among women, at which age the proportion turns in their favour. From 25 years, the rate of mortality constantly increased up to extreme age, though diarrhœa was generally the form which the epidemic assumed in the case of octogenarians.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Nov. 17, 1849.

CAUSES OF DEATH.	Total	Average of Five Autumns.
ALL CAUSES	892	1162
SPECIFIED CAUSES		1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	178	307
SPORADIC DISEASES:		
Dropsy, Cancer and other Diseases of uncertain or variable seat		49
Tubercular Diseases		
Diseases of the brain, Spinal Marrow, Nerves, and Senses		125
Diseases of the Heart and Blood vessels		
Diseases of the Lungs, and of the other Organs of Respiration		
Diseases of the Stomach, Liver, and other Organs of Digestion		65
Diseases of the Kidneys, &c ...		11
Childbirth, Diseases of the Uterus, &c.

MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the Diploma, were admitted members of the College at the meeting of the Court of Examiners, on the 23rd instant:—Messrs. Samuel Whitlaw, Lower Whitley, Cheshire; James Newham, Lynn Regis, Norfolk; Henry Parker, Sheffield; William Robert Stewart, Hackney; Henry Hervé Woolhouse, Army; Franklin George Evans, Cardiff, Glamorganshire; and John Weekes, Tavistock, Devon. At the same meeting of the Court Mr. Henry Loney passed his examination for Naval Surgeon. This gentleman had previously been admitted a member of the College, his Diploma bearing date May 29, 846.

APOTHECARIES' HALL.—Names of Gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, 22nd Nov., 1849:—William Spence Brown, Strood, Kent; James Mozley Stark, Gainsborough; Fortescue John Morgan, Henley-on-Thames; James Rigby, Stockport, Cheshire; James William Henry Veitch, Portsmouth.

THE FELLOWSHIP.—In consequence of the new regulations coming into operation early in the ensuing year, making it compulsory on all the junior candidates for the Fellowship of the Royal College of Surgeons, to undergo examinations in the classics and mathematics, upwards of thirty gentlemen, principally junior members of the College, have entered their names for the necessary examinations, which will take place at the College on Tuesday and Thursday next.

BENEFICENCE.—The late Mr. Lewis Morris Cuthbert, of Lyon-terrace, Maida-hill, has bequeathed 100l. to the Hospital in connexion with University College, the funds of which Institution have also been enriched by a further legacy of 100l., free of duty, from the late Mr. Wilkins, of Mackworth, Derbyshire.

OBITUARY.—On the 22nd instant, at Sydenham Kent, in the 71st year of his age, William Roberts Esq., surgeon, late of the 1st. Royals.—On the 25th at Weymouth, Dr. Carden, late Physician to the Bath General and United Hospitals.—Lately, at Runcorn Mr. Thomas Case, surgeon.

KING'S COLLEGE HOSPITAL.—At a Quarterly Court of the Governors of this Hospital, held on Wednesday last, it was stated, that the funds for the last quarter had proved deficient by nearly 600*l.* owing to the expenses incurred by the immediate admission and treatment of cholera and diarrhœa patients during the recent visitation. The Earl of Carlisle having been elected Vice-President of the Hospital, the resignation of the Duke of Sutherland from the office of President, on account of illness was received, the resolution expressing the regret of the meeting, and also its gratitude for the liberality and support evinced by His Grace towards the Hospital. Thanks having been voted to Lord Radstock (the Chairman) the proceedings terminated.

ROYAL DISPENSARY FOR DISEASES OF THE EAR, DEAN-STREET, SOHO-SQUARE.—The Quarterly Meeting of this Institution, founded for the relief of indigent persons labouring under Deafness and other Diseases of the Ear, was held on Wednesday last at the Dispensary. Dr. Richards in the chair. The Secretary read the amount of subscriptions, from which it appeared, that the Charity had been aided by the contributions of Her Majesty the Queen Dowager, His Majesty the King of the Belgians, Ladies Tilney Long, Atkinson, and Trundle; the Rev. R. A. Scott, the Lord Mayor, Captain, Jones, &c. The Committee solicited the aid of the affluent for this useful Charity, which was dependent upon the voluntary subscriptions of the benevolent. The Dispensary had afforded relief to an increased number of applicants, during the last quarter. The statistical account, Mr. Harvey stated to the meeting of the new admissions from July to September, is 250; cured 59. The Committee, therefore, solicit the contributions of the benevolent and charitable to enable them to meet the expenses of the Charity, and to permit of its more extensive usefulness. A vote of thanks was passed to Mr. Harvey, the surgeon, and to the Chairman, and the meeting separated.

SOCIETY FOR THE ABOLITION OF BURIALS IN TOWNS.—On Wednesday, a meeting of this Society was held at its rooms, Bridge-street, Blackfriars. The Chairman presented a scheme for extramural burial, as regards the metropolis, which was read by the Secretary. The measures recommended in this document were as follows:—"1. That a general system of extramural sepulture shall be forthwith organized throughout Great Britain. 2. That medical men be appointed to fill the ancient office of 'searcher,' and that no body be removed for interment without a certificate of death. 3. That the interment of the dead, during the summer months, within a period of —— days, be compulsory. 4. That for London, common land in the neighbourhood of railways should be appropriated for general cemeterial purposes, branch lines conveying the funeral trains into the ground itself, as proposed by Mr. Walker to the Select Committee on Interment in Towns in 1842. 5. That a central administration be appointed to undertake every service (except religious) connected with the burial of the dead at fixed and specific charges, which latter should not exceed certain maxima laid down therein. 6. That the duty of providing for the interment of the dead be exclusively confined to the aforesaid administration." The report was unanimously adopted, and the meeting directed that it should be printed and circulated.

RE-MODELLING OF THE METROPOLITAN SEWERS.—We understand that the Metropolitan Commissioners of Sewers have made their selection of a gentleman to fill the important post of Chief Engineer of the Commission, to whose invention and direction the entire re-modelling of our sewers and drains is to be committed. We forbear to say much about this gentleman, (Mr. Foster,) as the proposed appointment has not yet been confirmed; but we may state, that he is an engineer of first-rate talents, and has assisted in the construction of the great tubular bridge over the Menai Straits.

CARLISLE.—An investigation into the sanitary condition of Carlisle has been made by W. Rawlinson, C.E., the inspector appointed by the Board of Health. Evidence was given on the following points:—"The sewerage, drainage, and supply of water; the state of the burial-grounds; the number and sanitary condition of the inhabitants; the local Acts, of Parliament, if any, for paving, lighting, cleansing, watching, regulating, supplying with water, or improving, or having relation to the purposes of the said Acts; the natural drainage areas; the existing municipal, parochial, or other local boundaries, the boundaries which may be most advantageously adopted for the purposes of the said Act, and other matters. Mr. Steel, the chairman of the Corporation Committee, reported, that with respect to drainage and sewerage, Carlisle was very defective. Most of the drains are V shaped; others have flat bottoms—they have not been laid out upon any uniform system. They empty themselves into the Eden (the river that supplies Carlisle with water.) Those from the Aglionby lands terminated in the Petteril, which flows into the Eden. The majority are proprietary drains. For the last two years the Corporation have required that private drains should be made of six-inch glazed pipes, with socket joints for water-closets. The drainage work is superintended by the Corporation Inspector of Buildings. The sewers are only occasionally trapped for the private houses; in the streets there are only open gully holes. Among other evidence, the collection of midden-heaps was spoken of as a nuisance very injurious to health." In commenting on this statement Mr. Rawlinson observed, that it is highly important to take as large a view as possible of the effect such refuse may have upon the health of the people, because we are often led away to false conclusions. In the course of his inquiries in the several towns he had visited, he had seen very scanty privy accommodation, and other disgusting sights; but the worst cause of disease had been found to be large masses of filth accumulated in the shape of middens. The cholera raged fiercely in Alnwick, where in three weeks a year's population was swept off. It was curious to trace how closely the disease obeyed the law of settling itself where middens had been allowed to accumulate. It took the highest and most cleanly looking part of a particular district, and not the dirtiest part of the town.

TORQUAY.—Mr. Rummell, an inspector of health, has been examining Torquay lately, with the view of bringing it under the operations of the Board of Health. His investigations have shown the necessity of the inquiry.

CHOLERA AT PAULTON, SOMERSET.—The disease is at present making great ravages amongst the poor of the parish of Paulton, a locality containing about 2,000 inhabitants. The deaths up to Thursday, the 22nd of November, have been 33; there were four more deaths took place that day, and at present there are no signs of the pestilence abating. Paulton is situated about eight miles from Bristol.

TESTIMONIAL.—An elegant time-piece was recently presented to Mr. Kirkpatrick, surgeon, of Scolby Grange, by his friends and patients, as an acknowledgment of their gratitude and esteem for his professional and private character, and for the kindness and attention shown by him to the poor, for the last thirty years, and especially during the late epidemic. Dr. Allison, of Bridlington, presided at the meeting, and eulogised Mr. Kirkpatrick in a long and effective speech. Mr. K. responded briefly, but to the purpose.

MR. SANDS COX AND THE MIDLAND COUNTIES RAILWAY DIRECTORY.—It will be in the recollection of our readers, that Mr. Sands Cox some time ago brought an action against the Directors of the Midland Counties Railway, for his charge for amputating the leg of a poor man, and for two subsequent visits, rendered by the express order, in writing, of the Superintendent at Birmingham. It appeared that the poor man, Higgins, had had his leg crushed by a railway carriage having passed over it, and Mr. Cox, as we have stated, was sent to attend him by one of the principal servants of the Company. Higgins brought an action against the Company, which was compromised by the payment of a sum of money, and this, coupled with the fact that the superintendent was not authorised to call in surgical assistance on such occasions, and had acted on his own responsibility in this case, and not by the authority of the directors, caused a verdict to be given for the defendants, the judge and jury expressing a strong opinion in Mr. Cox's favour on the merits of the case. Mr. Cox avers, that in the agreement between the company and Higgins, it was stipulated that the former were to pay his (Mr. C.'s) charges, provided they were reasonable, but that this was purposely omitted in the memorandum endorsed on the brief, because the gentleman who held Higgins' brief did not consider him in any way liable. A considerable length of time elapsed; Mr. Cox paid his own legal expenses, and believed, as did his friends, that in consideration of the heavy loss he had already sustained, and equity, but not law, being on his favour, he would hear no more on the subject. It seems, however, that towards the end of last month, he received a notice from the Secretary of the Railway Company to pay their law expenses likewise. On the receipt of this, he wrote a spirited and manly letter to the secretary, pointing out the injustice of the case, and expressing his belief that, on a due knowledge of the facts, they would cease to urge his payment of the costs on their side. He concludes his letter thus:—"I wish it clearly to be understood, that I do not make an appeal *ad misericordiam*, my condition in life does not require that I should incur that degradation. I have forborne to pay your costs up to the present time, solely because I cannot bring myself to believe that you demand them, with a full understanding of the injustice of the claim, and because, many persons with whom I have conversed on the subject, have expressed a similar opinion. If you will only satisfy me by a line under the hand of your secretary, that you are in full possession of the facts and merits of the case, and that, with that knowledge, you require me to sustain a further loss, I will bring the matter to a close, by at once paying your demand." It is said, that at the meeting of the board, peremptory instructions were given to enforce payment of costs without delay; and that they have since been paid by Mr. Cox. If this be, indeed, true, we can only say, with the editor of the *Birmingham Journal*, who has just published Mr. Cox's letter with comments, that men in their corporate capacity will commit acts, which individually they would be ashamed of!

TO CORRESPONDENTS.

Mr. Quain's valuable Clinical Lecture "On some of the diseases of the Testis," is unavoidably delayed, in consequence of some imperfections in the illustrative wood engravings.

We regret to be obliged to solicit the kind forbearance of several correspondents, whose valuable communications, however, are in type. Our desire to comply with the wishes of many of our readers, and to complete Mr. Wardropp's work on the heart with as little delay as possible, is the reason for withholding, until next week, several letters, to which, otherwise, we would gladly have given a place in our present Number.

Our French correspondence arrived from Paris at too late an hour for insertion.

"L. M." writes:—"A patient labouring under erysipelas commencing at the foot and extending to the abdomen, with ulceration over the sacrum, is attended by a surgeon; can he recover his charges, which are disputed upon the ground that it is not a surgical case?"

[We refer our Correspondent to the opinions of our readers. We fear that, unless he is a Licentiate of the Apothecaries' Company, he cannot *in law* recover.]

'Juvenis" writes.—"Will you be so kind as name, in your next Number, the best work on Materia Medica for a young pupil. Also give Erasmus Wilson a hint that his Delineations of Cutaneous Diseases are in arrear."

There is no good work in the English language on Materia Medica for a young pupil. We shall be very glad to see the want supplied.]

"Mr. William Marshall's" communication has been received.

"A Respected Correspondent," who was "the intimate friend of the Siamese Twins when they were exhibited at the Egyptian Hall, in 1829," offers us "portraits and memoirs of these most amiable and interesting men." We fear we must, on behalf of our readers, decline the obliging proposal.

Our Friend who writes in pencil will observe that we have followed his directions. We are obliged by his commendation of our humble endeavours.

'Mr. Utermarch" has our thanks.'

"L. L."—We cannot conceive it to be lawful for any man, even though he be a medical man, "to hook his horse to a house-door, and thus obstruct the foot-path while he is visiting his patient within." Concerning the proposed advertisement, he must exercise his own judgment. *Both* will be best.

We are obliged by Mr. Cantrell's attention.

Mr. Mosgrove's (of the Bombay Army) valuable remarks on the predisposing causes and treatment of the Asiatic Cholera we shall speedily lay before our readers. Mr. Mosgrove is now in charge of an infirmary opened by public subscription, and we have pleasure in announcing his promise of favouring us with periodical reports. Indian practice cannot but be acceptable to our readers.

We have received Mr. Harvey's communication "On the artificial Tympanum," which we shall have much pleasure in inserting in our next Number.

Mr. Wiblin, of Southampton, is assured that his surgical essays will meet with our earliest possible attention.

Mr. Miller's" Cholera Return is acknowledged with thanks.

Mr. Davis" is thanked for his communication, which shall receive our most serious consideration. We do not insert his letter in our columns, because we do not know if it is intended for ourselves or for the public; but we will willingly publish any remarks upon the subject with which Mr. Davis will favour us.

"H. A." shall receive early attention. He must, however, remember that the "Medical Times" of the present day, and the "Medical Times" of past days, are not *alter et idem.*

Sarsus."—We shall insert Sarsus' letter next week.

We have received Mr. Hare's new edition of his work on spinal diseases, which will be reviewed as speedily as possible.

Mr. Maclure's" request will be attended to.

ORIGINAL LECTURES.

LECTURES ON THE CHEMISTRY OF THE POISONS; OR, ON PRACTICAL TOXICOLOGY.

SHOWING THE APPLICATIONS OF CHEMISTRY TO THE DISCOVERY OF CRIME.

By H. LETHEBY, M.B., Lond:
Lecturer on Chemistry at the Medical College of the London Hospital.

LECTURE X.

Nitric acid.—Composition of the pure acid —Of the commercial varieties,—the Monohydrated, Sesquihydrated, Binhydrated, Tetrahydrated Acids, &c.—Physical properties of nitric acid its specific gravity.—Table of specific gravities.—Table of boiling points —Table of congealing points.—Chemical properties of the acid affinity of the acid for water —Table of condensation.—Action of nitric acid on litmus paper action of the acid on metals, as copper, silver, mercury, bismuth, tin, zinc, iron, arsenic, and antimony.—*Rationale* of its action, according to Millon: action of the acid on metalloids, as phosphorus, carbon, sulphur, &c.

NITRIC ACID:

Called also azotic acid, fuming spirits of nitre, Glauber's spirit of nitre, aqua-fortis, and solutive water. This liquid, to quote from Mr. Taylor, seems to have been first used as a poison about the middle of the fifteenth century, but although it is much more used in the arts than oil of vitriol, yet cases of poisoning by it are by no means so common. Tartra was only able to collect fifty-six cases, extending over a period of nearly four hundred years; and it appears, from the return of inquisitions for 1837 and 1838, there were only two instances reported to have occurred in England during those two years. "I have," says Mr. Taylor, "only met with one instance, where it was poured down the throat of a child for the purpose of murder."

COMPOSITION OF THE SEVERAL VARIETIES OF AQUA-FORTIS.

1. *Pure or Anhydrous Nitric Acid* is generally regarded as a compound of one equivalent of nitrogen equal to 14 parts, and five equivalents of oxygen equal to 40 parts · the combining proportion of the acid is, therefore, 54, and its formula is NO^5.

But, until very recently, such an acid had never been isolated; for, on attempting to separate it from the water with which it is combined in aqua-fortis, or from the bases with which it is united in its saline combinations, the anhydrous acid instantly resolved itself into oxygen and nitrous acid; in consequence of which all chemists were agreed in regarding the dry acid as a hypothetical body. This fact has even been made use of by Liebig and his followers, in order to illustrate their peculiar views with regard to the constitution of acids generally; and Schonbein has taken advantage of it in his attempts to show that liquid nitric acid is a compound of nitrous acid and ozone, or peroxide of hydrogen. Very recently, however, M. Deville, of Besançon, has presented to the Parisian Academy of Sciences, through the agency of M. Dumas, a specimen of pure anhydrous nitric acid, in the form of large brilliant colourless crystals. These crystals were obtained by passing pure dry chlorine gas over nitrate of silver—the salt being first heated to a temperature of 200° Fahr., and then, directly after decomposition had commenced, the heat was lowered to about 140° or 150° of Fahr. At this temperature pure nitric acid continued slowly to distil over, and it was easily condensed and obtained in the crystalline form, by collecting the acid in a receiver kept cool by means of ice. The crystals thus procured were large colourless six-sided prisms; they melted at a temperature of 85° Fahr., and the resulting liquid boiled at about 118° Fahr. In distilling the acid, however, it always underwent a partial decomposition, being resolved into nitrous acid and oxygen. The crystals of the acid are said to be very soluble in water, and during their solution they produce a great elevation of temperature. According to Dumas, the crystallised acid is not a permanent compound; for the specimen furnished to him by Deville underwent spontaneous liquifaction, and, on attempting to recongeal the liquid, it was suddenly resolved into oxygen and hyponitrous acid, a change which took place with explosive violence.

2. *Commercial or Hydrated Nitric Acid.*—The nitric acid, which we are accustomed to meet with in commerce, is a liquid of very variable strength; for it consists of the preceding pure acid in combination with various proportions of water; chemists, however, are not yet agreed as to the nature of these combinations; nevertheless we may, I think, conclude, from the facts already presented to us, that there are at least two definite compounds of nitric acid and water, namely, a protohydrate and a tetrahydrate; and it is more than probable that there are other combinations of a like nature, although the evidence concerning the latter point is not so clear or satisfactory.

(a) *Monohydrated Nitric Acid* has been frequently referred to by chemists; but I am not at all certain that the compound in question has been as frequently obtained. Mr. Smith, however, of University College, has lately made a re-examination of this subject. He has carefully prepared the pure monohydrated acid, and his chemical report thereon has cleared away many of the discrepancies which have hitherto clouded our inquiries into this matter.

This Author states, that when the strongest commercial acid, having a density of 1500, is distilled with half its bulk of oil of vitriol, then decolorized, re-distilled at a low temperature, (from 190° to 200°,) again decolorized, and so on for three or four times successively, we may obtain an acid which cannot be further concentrated. It presents itself as a colourless liquid, having a density of 1517; it contains 85 71 per cent. of dry acid; from which it is evident that it is composed of one equivalent of nitric acid equal to 54, and one of water equal to 9. Its equivalent, therefore, is 63, and its formula is $NO^5 + HO$.

(b) *Sesqui-hydrate of Nitric Acid.*—This acid, according to Mr. Richard Phillips, is obtained when aqua-fortis is manufactured, after the manner recommended by the London College; that is, according to the directions given in the London Pharmacopœia. He states, that the specific gravity of this acid is 1503·3 or 1504; that it contains 80 per cent. of real acid; and that its formula is $2\ NO^5 + 3\ HO$. It is not, however, a stable compound, for it is resolved by heat into the proto and tetrahydrates

(c) *Binhydrate of Nitric Acid* is a compound which is often referred to by chemists; Mr. Graham, for example, says, that a second acid appears to exist, having a density of about 1480, which has little or no action upon tin, iron, and some other metals. Millon, also, in his monograph upon nitric acid, states, that there is a hydrate with this composition, but that it is only obtained to any extent by operating upon a large quantity of very concentrated acid. Seventeen pints of the strongest aqua-fortis only afforded about one pint of this acid. It appears, however, from the investigations made by Mr. Smith, that this so-called binhydrate has no real existence; for, on heating a liquid of sp. gr. 1496, which contains 75 per cent. of real acid—a proportion equal to that of the hydrate in question —it was resolved into two compounds, namely, into the proto and tetra hydrates just mentioned.

(d) *The Tetrahydrate of Nitric Acid* has been recognised as a distinct compound ever since the time of Dalton, whose inquiries served to establish the truth of this principle, namely, that very strong nitric acid became weaker by boiling, and that the weaker acids gradually became stronger during their distillation; so that, in fact, the ordinary varieties of nitric acid are all resolved by heat into one compound, viz., the tetrahydrate; the specific gravity of which, according to Mr. Smith, is 1424, it contains 60 per cent. of real acid, and its formula is $NO^5 + 4\ HO$.

(e) *Another Hydrate* has been mentioned by Millon, who states, that when the last-named compound is undergoing the process of distillation, a moment arrives when there is a sudden disengagement of nitrous fumes, when the thermometer, which had previously risen to 266° or even 273° Fahr. falls 14 or 18 degrees, and when the residual liquor, containing 57 per cent. of nitric acid, has a density of 1405. This acid, according to Millon, is a distinct hydrate, and its formula is $2\ NO^5 + 9\ HO$.

PHYSICAL PROPERTIES OF LIQUID NITRIC ACID.

Pure nitric acid is a colourless fuming liquid. The acid of commerce, however, is generally more or less coloured, and the tint may vary from a pale yellow up to a deep orange red, according to the proportion of nitrous acid present in the liquor. Occasionally, too, it has a green, or even a deep blue tint, in consequence of its containing hyponitrous acid, —an impurity which, together with the preceding, I shall consider more fully hereafter.

The Specific Gravity of aqua-fortis varies according to its strength; that known in commerce by the name of double aqua-fortis has a specific gravity of from 1500 to 1360, while that in ordinary use, called single aqua-fortis, has a density somewhere about 1220. Again: there is much difference of opinion with regard to the density of the strongest fuming nitric acid. The Edinburgh College fixes its specific gravity at 1500; and Dr. Ure states, that this was the density of the acid which he obtained when he slowly distilled it from regular prisms of nitre, which were acted upon by concentrated oil of vitriol. Mr. Phillips, however, and the London College, have fixed the strength of the acid at 1504. Gay Lussac obtained an acid which had a density of 1510, and Thenard's acid had a specific gravity of 1513. The acid which you see here, and which I procured by two successive distillations from concentrated oil of vitriol, has a density of 1511; Pelouze, however, and Proust and Millon state, that their acids, obtained in the same way, had a specific gravity of 1520, while Mitscherlich's acid had a density of 1521, and Smith's of 1522. Hope has stated, that when we decompose perfectly dry nitre, by means of recently boiled sulphuric acid, we may obtain an acid which has a density of 1540. I can confirm the statement, for here is an acid obtained in the manner described, and, as you will perceive, it has a specific gravity of 1543. Davis's strongest aqua-fortis had a density of 1550; Kirwan's that of 1554·3, and Rouelle is said to have procured an acid whose specific gravity was as high as 1583.

Many of the discrepancies here referred to, have doubtless arisen out of the circumstance, that the acids described were not pure, but were contaminated with various proportions of nitrous acid, hyponitrous acid, and perhaps sulphuric acid, or even saline matters, all of which impurities would tend to give a false value to the strength of the acid: it appears, in fact, from the experiments so recently made by Mr. Smith, that an acid having a density of 1522 is lowered to that of 1503, when it is deprived of the nitrous acid ordinarily contained in it; and Mr. Richard Phillips has shown, that when an acid of specific gravity of 1497 is saturated with binoxide of nitrogen, that is, with nitrous and hyponitrous acids, its density rises to 1541.

Again: the same cause of error has operated in giving a false value to the saturating powers of such impure acids; for it appears from the investigations of Kirwan, Davy, Wollaston, Phillips, Dalton, and Ure, that an acid of specific gravity 1500, may, if tested, by its saturating power alone, exhibit a strength of from 68 to 91 per cent. of real acid. Some of those discrepancies have, however, been removed by the inquiries of Dr. Ure, who has drawn up the following Table, in the hope of exhibiting the relative strengths of nitric acid of different densities, and I may remark, that, although this Table does not correctly represent the composition of these acids, yet it is sufficiently near to the truth for all ordinary purposes; and that it accords

pretty well with the results obtained by Dr Thompson and others:—

TABLE exhibiting the SPECIFIC GRAVITIES and PERCENTAGE STRENGTHS of various Solutions of NITRIC ACID in WATER.

Boiling point of the Acid.—Notwithstanding that this part of our inquiry does not possess much interest in a medico-legal point of view, yet it is necessary for me to refer to it, in order that I may complete my account of the properties of this liquid. According to Mr. Dalton, the following represents the boiling points of acids of different densities:—

Acid of sp. gr. 1500 boils at 210° Fahr.
" 1450 " 240° "
" 1420 " 248° "
" 1400 " 247° "
" 1350 " 242° "
" 1300 " 236° "
" 1200 " 226° "
" 1150 " 219° "

From which it will be manifest that both the strong acids and the weak acids boil at comparatively low temperatures; and that the boiling points gradually rise until the liquid acquires a density of 1420; when, in fact, it becomes the tetrahydrate, and contains 60 per cent. of real acid. Millon states, that all the acids having a density above 1500, begin to boil at the temperature of 187° of Fahr., and that the boiling point gradually rises until it arrives at about 253° Fahr., where it remains constant for some time. Towards the end of the distillation, however, this observer found that the thermometer rose to 266° Fahr., or even occasionally to 273°; and he remarked, that during the progressive ascent of the mercury it stood for a short time at the following points, namely, at 194°, 222°, and 232°. It appears, moreover, from Millon's investigations, that the quantity of the liquid, its density, the presence of points in the retort, the mode in which the heat is applied, and several other circumstances, affect the boiling point of this acid. When experimenting on the pure acid, Mr. Smith found that those solutions which had a density of 1500 began to boil at about 190° Fahr., and that during their distillation the thermometer gradually rose to 250°. On instituting some inquiries into the boiling points of the two well-known hydrates, viz., the mono and tetra hydrates of nitric acid, he noticed that the former, which has a density of 1517, boiled at 184° Fahr., and that the latter, whose specific gravity is 1424, boiled at 250° Fahr. Acids of intermediate strength boil at intermediate points.

Again, with regard to the congealing points of nitric acid, it appears that the pure anhydrous acid solidifies at a temperature a little above the freezing point of water, while an acid having the density of 1500 congeals at 40° below the zero of Fahr.; of 1400, at 41°; of 1330, at 2°; of 1215, at 40°. So that, as in the preceding case, the tetrahydrate is the compound which requires the greatest alteration of temperature to produce a given amount of change in it.

CHEMICAL PROPERTIES OF NITRIC ACID.

Strong solutions of aqua-fortis are not very permanent compounds; for they all undergo more or less change by keeping, and this change is still more readily effected when the acid is exposed to light, or to the influence of a moderately high temperature. Under these circumstances the liquid loses oxygen, evolves nitrous acid, and becomes coloured. Of all the acids, however, that which has a density of .1424 is, as we have already seen, the least prone to decomposition; for it not only keeps better than the acids of other strengths, but it also boils at the highest temperature, distills nearly unchanged, and requires the maximum degree of cold to freeze it.

Affinity of Nitric Acid for Water.—Aqua-fortis fumes in the air, and attracts moisture from the atmosphere, simply by reason of its affinity for water; and, as in the case of oil of vitriol, strong nitric acid combines with water with considerable energy, evolving, under these circumstances, a high degree of heat. Dr. Ure states, that the greatest amount of condensation takes place when 58 parts by weight of the strongest acid (sp. gr. 1500) are mixed with 42 of water. At this time a condensation takes place to the amount of 7·5 in the 100, and the temperature of the liquid rises from 60° to 100° Fahr. This experimenter has also remarked, that, when 90 parts of the strong acid are mixed with 10 of water, the 100 volumes become 97; and that when 10 parts of the same acid are combined with ninety of water, the resulting volume is 98. A glance also at the table just quoted from Dr. Ure will show, that, upon mixing a given weight of any acid, whose specific gravity is above 1378, with an equal weight of water, the real density of the resulting mixture is greater than the calculated density. This fact is illustrated in the following table:—

TABLE showing the REAL and CALCULATED DENSITIES of MIXTURE of equal weights of ACID and WATER.

Sp. Gr. of Acid used.	Calculated Sp Gr. of resulting Acid.	Real Sp Gr. of resulting Acid.	Total Increase of Density.
1500·0	1250·0	1294·7	44·7
1485·0	1242·5	1276·5	34·0
1467·0	1233·5	1258·3	24·8
1446·0	1223·0	1240·2	17·2
1422·8	1211·4	1221·2	9·8
1397·8	1198·9	1201·9	3·0
1378·8	1189·1	1189·5	·4

In the course of my own experiments I have found that equal parts by weight of strong nitric acid, of sp. gr. 1500, and water gives an increase of temperature which amounts to 140° Fahr.; that one part of such acid with three of water gave a heat of 130° Fahr.; and that one of acid with six of water produce a temperature of 100° Fahr.; the densities of the resulting liquids being 1300, 1176, and 1090.

Action of Nitric Acid on Litmus Paper.—The acidifying power of this acid is very great, for it communicates a red colour to litmus paper, when the liquid is diluted so as to contain only ·27 per cent. of acid.

Action of Nitric Acid on the Metals.—With few exceptions, all metallic bodies act with considerable energy on ordinary samples of nitric acid, the metals themselves appropriating oxygen and liberating nitrogen, protoxide of nitrogen, binoxide of nitrogen, hyponitrous acid, or nitrous acid, according to the violence of the re-action. It appears, moreover, that all those metals which have the faculty of decomposing water, or of being acted upon by hydrochloric acid at ordinary temperatures, as, for example, zinc, iron, tin, &c., invariably produce a small amount of ammonia at the time when they are thus re-acted upon.

A consideration of the many facts which bear upon this part of our inquiry, will show that there are a great number of circumstances which influence the chemical changes to which we are now referring. It is found, for example, that most of the metals, but especially iron, copper, and tin, will exhibit either an active or a passive state, according to circumstances:—that is, they will either re-act with much energy upon the acid, or they will remain in it without producing any considerable change. Millon, who has devoted much attention to this subject, states, that the oxydation of the metals in nitric acid is subordinate to the concentration of the acid, to the temperature, to the presence of nitrous acid, and to the solubility of the resulting compound in the acid used. These principles extend to all the metals, but they present certain modifications, the chief of which it is very important that you should be acquainted with.

Copper is not attacked by nitric acid of specific gravity 1070, at a temperature of 60°, unless a little nitrous acid be present, and then the action goes on energetically. The application of heat, also, instantly causes the pure acid of this strength to re-act upon this metal. Again: Millon has found, that, contrary to what is generally stated, pure concentrated nitric acid, of specific gravity 1552, attacks copper with extreme violence at ordinary temperature; and this, he says, takes place with all acids which have a density intermediate between the last-named and 1070. He states, however, that a cold of 32° Fahr. will completely check this action; and, in the case of the acid sp. gr. 1552 and 1550, the copper becomes coated with a bluish crust, which entirely protects it from further action, even when it again reaches the ordinary temperature. Acids of sp gr. between 1450 and 1400 leave the copper in a metallic state, so long as they remain at a temperature of 32° Fahr.; but, when the temperature rises, they cover the copper with a bluish crust, and the action proceeds no further, unless the tube is frequently shaken; whilst weaker acids commence their action as soon as the heat is raised; though it be but a little, the time of commencement, however, varies with the strength of the acid; for he found that an acid of sp. gr. 1217 began to act on copper at a temperature of 50° Fahr., while that of sp. gr. 1108 commenced its action at about 36° Fahr.

Silver and Mercury present very nearly the same re-actions as the preceding.

Bismuth and Tin, however, operate in a different manner; for they preserve their metallic lustre in all the acids which have a density above 1500; in fact, Mr. Smith states, that the pure monohydrated acid may be boiled upon tin without undergoing decomposition. Weaker acids, as, for example, those which have a density between the last named and 1110, act with considerable energy on these metals, even at ordinary temperatures; but, if we dilute the acid so as to bring its density down to 1108, the metal is not attacked unless we apply heat to the tube.

Zinc is a metal which exhibits re-actions almost the reverse of the preceding, for it is, at ordinary temperatures, violently acted upon by nitric acid, whether the acid be strong or dilute. If, however, we make use of an acid whose specific gravity is at or above 1500, and take care to reduce it to the temperature of zero, the metal will not be attacked beyond being coated with a slightly yellowish white crust, and, if we employ weaker acids than this, the zinc perfectly retains its metallic lustre while it is under the influence of the temperature just mentioned.

Iron, as is well known, displays many peculiarities with regard to its action upon nitric acid. Schonbein, Faraday, Reuben Phillips, and others, have alluded to a great number of circumstances under which this metal retains its passive condition in nitric acid; and, although this is not the place for a full inquiry into the matter, yet I may, perhaps, allude to one or two of the results recently obtainedby Millon. He states, that when small balls of well-potisoed iron were pl aced in nitric acid of specific gravity 1500, they were sometimes covered with a black, and sometimes with a blue crust. When in this condition, the metal is not attacked by any acid, whether it be weak or concentrated, provided the temperature of the liquid is not raised. The protecting crust, according to Millon, exhibits the characteristics of protoxide of iron, a compound which is perfectly insoluble in nitric acid. Smith, also, states that the pure monohydrated acid may

be boiled upon iron without undergoing decomposition.

Metallic Arsenic is not attacked at ordinary temperatures by acids of any strength, and *antimony* is not acted upon unless the acids are very concentrated.

Lastly, it has been affirmed by Millon, that the agent which effects the oxydation of all the metals is nitrous acid—an acid which readily yields its oxygen to the metallic body, and then, by evolving binoxide of nitrogen, and re-acting upon the nitric acid, it produces a new proportion of nitrous acid, so that the merest trace of this potent element in the aqua-fortis employed is sufficient to establish, under favourable circumstances, an energetic and continuous action upon the metal: while the presence of any compound which has the faculty of appropriating the binoxide thus formed; as, for example, a little protosulphate of iron, will completely put a check upon the continuance of these changes. Kulmen, Dumas, and others have also noticed, that when any acid is used, in conjunction with the nitric, having the power of liberating hydrogen, the re-actions are to a certain extent altered; for the binoxide, instead of attacking the nitric acid, yields up its azote to the hydrogen, and thus gives rise to the formation of ammonia. This fact is of some importance to us in our analytical inquiries, and I shall take leave to discuss it somewhat fully hereafter.

Action of Nitric Acid on the Metalloids.—This acid parts with its oxygen so readily, that it acts with considerable energy on all the solid nonmetallic substances: some of them, as phosphorus, decompose the acid at ordinary temperatures; while others, as carbon and sulphur, require the aid of heat for the full manifestation of such a re-action. The effects, however, are not of such moment to you, and, therefore, with this slight reference to them, I shall pass on to consider the nature of the changes which take place when nitric acid is brought into contact with the commoner sorts of organic substances. This inquiry will constitute the subject of our next lecture.

ORIGINAL CONTRIBUTIONS.

CASES OF CHOLERA TREATED BY CALOMEL AND IPECACUANHA.

By JOHN W. TRIPE, M.D., M.R.C.S., &c.

In the early part of the present epidemic of cholera I was exceedingly unfortunate in its treatment, and therefore tried other means than those usually employed. The exhibition of stimuli and opium, of calomel and opium, either with or without chalk mixture, were all used unsuccessfully, and it was not until calomel and ipecacuanha were given in the doses to be mentioned, that I obtained any success. Under these circumstances, I have drawn up a brief history of all the earlier cases in which this treatment was adopted, that the Profession may judge of its efficacy.

Case 1.—Aug. 21, 8 a.m., Mrs. G., aged 35, visited on the 18th inst. a sister who lived in an infected locality, and was labouring under the disease. During last night she was attacked with severe diarrhœa, vomiting, and pains of the stomach. There were not any cholera cases in her neighbourhood.

When she first applied for assistance she was in a state of incipient collapse. At 2 p.m., her condition was as follows:—Pulse scarcely perceptible at the wrist, 120; skin cold and covered with a clammy sweat, eyes sunken, tongue livid, skin of fingers corrugated, rice-water dejections, vomiting, cramps in the legs, thighs, and stomach, vox cholerica, and suppression of urine.

The treatment, from the first, *i. e.*, 8 a.m., had consisted in the administration of 1 gr. of calomel and ½ gr. of ipecacuanha every quarter of an hour, and chalk mixture, with catechu every four hours. No opium or stimuli. Cold water, and cold milk and water for drink.

She gradually recovered from this stage, and became warm, but afterwards relapsed into her former condition. The cretæ mixture was discontinued, but the powders were persisted in, and she eventually recovered.

The secondary fever was treated by five grains of carbonate of ammonia, and ten minims of laudanum every four hours, and as the vomiting became urgent again on the third day, by the application of a blister to the epigastrium. The patient was not convalescent for fourteen days, the fever being typhoid in type.

Case 2.—August 22, 6 a.m.—Mrs. J., sister to Mrs. G., visited the latter on the 20th inst., went to bed in very good health last night, and was seized about 2 a.m. with cramps, vomiting, and diarrhœa. When I saw her at 6 a.m., she was in the algide stage, the pulse being imperceptible at the wrist, hands cold and wet, like those of a corpse after being dipped into cold water, fingers shrivelled as those of a washerwoman. Face shrunken, eyes sunk and red, tongue purple, cold, and furred in the centre; skin of the whole body of a purplish tint and cold. Purging severe and constant, stools of a light brown colour; no secretion of urine; cramps of the upper and lower extremities very severe, and slightly of the abdominal muscles.

The treatment was similar to that employed in Mrs. G.'s case, except that four ounces of wine was given between 1 p.m. and 3 p.m. She died a few minutes after 3.

Case 3.—August 24, 1 a.m.—Mr. S. had diarrhœa, vomiting, and cramps, at seven o'clock last evening, and procured a bottle of chalk mixture and catechu. He became choleraic, as I was told, about eight, but did not apply for further assistance until 1 a.m. The powders of calomel and ipecacuanha were given as above, but he died within two hours after they were commenced with. The usual symptoms of malignant cholera were manifested in this case.

Case 4.—August 27, half past 8 a.m.—Captain C., aged 35, a strong healthy man, began to purge and vomit about 2 a.m., but did not send to me until half past 8. He was at that time in a state of decided collapse, being cold and blue. Ordered half a grain of ipecacuanha and one grain of calomel every quarter of an hour. At 2 p.m. he presented the appearance of a person suffering from the disease in its most malignant form; his voice being almost lost, the pulse at the wrist imperceptible, hands and fingers wet and cold, cramps of the upper and lower extremities very severe; rice-water discharges from the bowels, which he passed in bed involuntarily. The diarrhœa and vomiting are not so urgent as at 8 a.m. Suppression of urine.

Since I first saw him, he had taken twenty powders; he was ordered to continue them every quarter of an hour with a table-spoonful of cold water after each, and a little cold milk and water occasionally. At 4 p.m. the pulse became slightly perceptible at the wrist, but not sufficiently so to be counted; at five it was thready, and 160 per minute. He recovered gradually; but suffered most severely from secondary fever, which was typhoid.

The treatment, during this stage, consisted of five grains of carbonate of ammonia, and one drachm of tincture of bark every four hours in one ounce of water. The mouth was severely affected with the mercury, but the symptoms of amendment commenced before the gums became raised.

Case 5.—August 28.—Mrs. W., living in Stepney, had diarrhœa of an ordinary character for three days before any symptoms of cholera showed themselves, which they did this day, at about three a.m. Four days prior to her attack, a lodger had been taken out of her house to the workhouse whilst suffering from the malady. At half-past six a.m., she was in a state of partial collapse; the ordinary change in the features, voice, and tongue, as well as the cramps, peculiar diarrhœa, and sickness, characteristic of the algide state, were all present. At ten a.m., her pulse could scarcely be felt, skin of fingers corrugated, hands quite cold and moist, cramps worse, sickness and purging less. The powders had been exhibited with tolerable regularity, eleven having been given. At three p.m., slight symptoms of re-action presented themselves, and increased until the secondary fever became very great. On the third day she became delirious tongue brownish-black, and dry, gums covered with sordes, and readily bled; no mercurial fœtor. Treated with tincture of bark, aromatic spirit of ammonia, and 6 oz. of wine daily. She recovered perfectly by Sept. 10th.

Case 6.—Aug. 30.—At 10 a.m., was called to Mr. W., who had become affected during the night with severe bilious diarrhœa and vomiting, cramps of his limbs, spasms, general coldness, especially of the extremities, suppression of urine, and a slight diminution in the power and tone of his voice. He had taken, before I saw him, a mixture of chalk, catechu, and laudanum, but without benefit. There were not any rice-water purgings or very marked collapse, the pulse being readily perceptible. The powders of calomel and ipecacuanha were given in the ordinary way; after the fourth, the vomiting ceased, and after the ninth, the purging also stayed, but the cramps became very severe. When he had taken thirty powders he had much improved, and at 9 p.m. was out of danger. He recovered without any subsequent fever or salivation.

Case 7.—Sept. 5.—Mrs. McC—, aged 22, lost her husband and child from cholera on the 2nd inst. She removed next day into a street in my neighbourhood in which no case of the disease had hitherto shown itself. On the following day, the 4th, her bowels became relaxed, and during the night, *i. e.*, at 4 a.m. of the 5th, she sent to my house. She was then in the early stage of cholera. Treatment, calomel and ipecacuanha as usual. At 12 a.m., the disease had reached its climax, her countenance being choleraic, hands and feet blue, cold, and damp; the body rather warm, eyes injected and sunken, vox cholerica, tongue purplish and furred, cramps, rice-water dejections, and cessation in the secretion of urine. The powders were still continued, and in four hours and a-half the vomiting and purging ceased; they returned next day, and were stayed by carbonate of soda and laudanum. The secondary fever assumed, as usual, the typhoid type, and she was convalescent on the 12th.

Case 8.—Sept. 7.—Mrs. W., aged 26, expects to be confined daily. She was seized last night with diarrhœa and vomiting, and this morning with cramps. When I saw her at 10 a.m., she was suffering from cholera. The disease assumed the same form as in the preceding case, collapse coming on at 11 a.m., and lasting for about six hours. Her tongue blue; face and skin dusky; extremities cold; cramps very severe; pulse 120. She was treated by the powders, as in the other cases, and was going on favourably the next day, when labour came on and passed through its ordinary course, until it was completed by the birth of a dead fœtus and the expulsion of the placenta. She sank in thirty-six hours, with symptoms of puerperal fever.

Case 9.—Sept. 8.—Mrs. M., aged 33, has had diarrhœa for the last two days. She first perceived the rice-water purging and the cramps about 2 a.m., and about an hour afterwards sent for a neighbouring medical practitioner, who prescribed a chalk and catechu mixture. She became much worse, and sent for me at half-past six, a.m. She was then in a state of collapse, with constant vomiting and purging, cramps, and that feeling of utter prostration so common in the disease. The powders of ipecacuanha and calomel were given; the vomiting and diarrhœa soon ceased, but returned the next day. The secondary fever was very great, and lasted for fourteen days, when she sank. Her friends were not in a condition to procure her the necessary support, and yet refused to receive any aid from the parish.

Case 10.—Sept. 8, 3 a.m.—Mr. B., a strong healthy man, sent for me to attend him for a diarrhœa. He then had rice-water alvine dejections, but no cramps. At eight, he had the symptoms of malignant cholera, including vox cholerica, purplish tongue, cold clammy skin, non-secretion of urine, &c. Was ordered a powder every quarter of an hour, and cold water for drink. He became worse during the next two hours, at the end of which time the surface of the body began to get

warm. At the expiration of six hours he was comparatively comfortable. He had but little secondary fever.

Case 11.—Sept. 8.—R. M., aged 7, living in the same house with Mrs. M'C., was this day attacked with the disease, which assumed a malignant type, and pursued a course similar to that described in Mrs. M'C.'s case, except that the collapse was not so intense. He was treated in the same way, and with a similar result. The vomiting returned a few hours after its first suspension, and required a blister to the epigastrium before it finally ceased. Fever of a typhoid type supervened on the second day after the diarrhœa ceased, and lasted until the fifth, when it gradually subsided.

Case 12.—Sept. 9, 9 a.m.—John K., aged 42 complains of constant and severe rice-water purging, of vomiting, cramps, and great prostration. His features are shrunken; tongue purplish and furred; feet and hands cold; body warm; urine suppressed. These symptoms came on about two hours ago. The powders were administered in the usual doses and with the usual frequency. By the evening he had considerably improved, so much so that the powders were exhibited every hour only. He had less subsequent typhoid fever than usual, and was convalescent on the fifth day. No salivation ensued.

Case 13. Sept. 10.—8 a.m.—Mr. B., aged 60, a stout healthy man, got up at his usual time, 6 a.m., and went out. He returned in a few minutes, saying that he felt very weak and poorly. In about half an hour diarrhœa and vomiting came on. When called to him he was in a perfect state of collapse, and presented all the signs of malignant cholera. His pulse was imperceptible at the wrist, skin of trunk and extremities cold and damp, skin of hands corrugated, tongue blueish, cold, and furred. The powders were given as usual, but he never rallied and died in the evening at eight.

Since the above, I have had many cases which have been treated on this plan, only two of which died in the algide stage. It would occupy too much space to give an outline of all my cases, and I have, therefore, preferred sending an abstract of the first thirteen only.

The vomiting and purging usually ceased in a few hours after the powders were commenced with, although the former occasionally returned, but was readily relieved by blistering, and a mixture of soda and laudanum.

In these thirteen cases, thus treated, five were fatal, three during the algide stage, and two during the subsequent attack of typhoid fever. Of the three deaths, which happened during the collapse, one occurred in two hours after the treatment was commenced with, and, therefore ought to be excluded. We should then have two deaths in this stage out of twelve cases.

Of the two deaths during the fever, one happened in a woman who brought forth a dead child, when apparently progressing favourably; and the other, in a woman who had not the necessary stamina to carry her through the disease, but who nevertheless lived until the fifteenth day, and then died from exhaustion, partly induced by want of proper food and attention.

Commercial-road, Sept. 26, 1849.

RETROVERSION OF THE UTERUS AS A CAUSE OF STERILITY.

By EDWARD RIGBY, M.D., &c., Senior Physician to the General Lying-in Hospital, Examiner in Midwifery in the University of London.

I must be permitted to give one more case of retroversion occurring in an unmarried female, as it illustrates several points besides the important one of relief being afforded by the use of the prone couch.

Miss D., aged 35; small, but well made.

July 31.—Complains of constant dull pain behind the symphisis pubis, or rather centrally in the pelvis, increased by moving; when very severe it becomes sharp no pain is felt on evacuating the bladder or rectum, or by sitting down upon a hard seat, but greatly aggravated by a rough carriage, and most of all by walking; bowels very confined tongue pale at the edges, and furred; headache catamenia latterly have been regular.

On account of weakness of the spine, dyspepsia, &c., she underwent the water cure at a place on the Rhine in its full extent of severity five years ago, from which time she dates her present symptoms. Six months ago she consulted a practitioner of eminence, who ascertained the presence of ulceration, and relieved her considerably, though temporarily, by the application of argenti nitr.

℞ Extracti Taraxaci, ʒi. o. n. ℞ Ferri sulphati gr. xvj.; magnesiæ sulph. ℥i.; acidi sulph. dil ʒi.; syrupi rhœados, ℥ss.; aquæ menthæ pip ℥viiss. M. ft. mistura cujus sumat cochl. magna ij. primo mane vel. bis die.

August 2.—Was in much pain after taking the medicine; bowels copiously relieved of solid fæces twice, but without abatement of pain. Rep.

August 4.—Bowels well and copiously relieved the evacuations still are not fluid; she now felt relieved for a short time afterwards; the head is easier; the tongue quite natural.

August 5.—Bowels still copiously opened evacuations not fluid; feels generally better.

Examination per Vaginam.—The uterus is retroverted; the fundus pushed down towards the left sacro-ischiadic notch. Rep. Med. Let her use the prone position.

August 8.—Feels much better; likes the prone position; has been quite free from pain. Bowels moderately open. Rep.

11.—Much better. Bowels moved without medicine. Feels great relief in the prone position.

℞ Liq. taraxaci, ʒi.; inf. gentianæ co. ℥i ter die. Rep. Mist. ferri c. magnesia sulph., o. m.

13.—Catamenia ought to have appeared yesterday, but did not; feels much better and easier. Rep.

20.—Feels weak. Lips and tongue pale; vertex headache.

Mist. Ferri citratis effervescens bis die. Rep. Mist. Ferri sulph. c. magnes. sulp. o. m.

22.—Much of her old pain in the lower part of the pelvis. She has overwalked herself, and, in all probability, displaced the uterus. Bowels open; feels stronger. Rep.

Sept. 5.—As she was not relieved by a good trial of the prone position, I examined the uterus a few days ago, found it again retroverted and replaced it. Still, however, she is in pain, and, at times, the prone position brings on pain about the symphisis pubis, as if, after a while, from the lax state of the soft parts, the fundus inclined too much forwards and became anteverted, so that now I desire her to use the prone or supine position according to her feelings.

℞ Confect. rosæ, ℥i.; acidi sulph. dil. ʒi.; decoct. cinchonæ, ℥xij.; misce. coque & cola bene. Ft. mist. cujus sumat coch. magna, ij. ter die. Decoct. quercûs c. alumin, ft. injectio.

25.—Has been much better until yesterday, and has regulated the position of the body by her sensations, but during the night she was awoke by a return of the old pain, which has continued very severely ever since, nor has she been able to relieve by the prone position. She is much depressed in consequence.

Examination per Vaginam.—The fundus is strongly retroverted, and appears to be a good deal fixed; I replaced it, and advised her, whenever she has a return of these symptoms, indicating a displaced condition of the uterus, to put herself upon the knees and elbows. Rep. Med.

28th.—Finds great benefit from "the extra prone position," as she calls that of the knees and elbows; she uses it for about three minutes at a time, and entirely relieves the pelvis from the weight of the superincumbent viscera. Is returning to her house in the country.

Oct. 20.—Bore her journey well; has had little or no symptoms of retroversion since; is in good health, beyond suffering from considerable irritation of the vagina.

℞ Liq. plumbi diacetatis, ʒii.; decoct. papav. ℥viij., M ft. lotio.

℞ Plumbi diacet. [illegible]) extr. conii. a.a. gr. x.; pulv. acaciæ, ʒss. [illegible] brium.

November 25.—[illegible] her thanks for her improved [illegible] now almost for- [illegible] t, as well as difficulty standing, and [illegible] so much better as to be able to drive out pretty regularly between two and three hours without feeling any worse. I can also walk a little, but am very cautious in this respect, in the great fear of bringing on a relapse. I have found the greatest benefit from all the varieties of prone position, and have been, and am still very persevering in adopting them; kneeling on a footstool, with my forehead on the ground, has been very effective."

It is not always easy to assign the precise date of these displacements, nor is it generally of much consequence; suffice it to say, that the ulceration was most probably a result of, and therefore subsequent to, the retroversion, having been produced by the great engorgement of the anterior lip of the os uteri, which so frequently exists in these cases. If habitual costiveness in a lax flabby state of the soft parts had not been the original cause, at any rate, it was now the means by which the fundus was not only retained in its retroverted state, but forced down deep and to the left side, so as to be not far from the sacro-ischiadic notch. Although her symptoms gave strong reason to suspect the presence of retroversion, I did not propose an examination until I had satisfied myself that the bowels had been thoroughly unloaded; and the treatment for this purpose disclosed a far greater amount of accumulation than I had expected. When I did pass the uterine sound, I not only found my suspicions fully verified, but the reposition of the uterus produced instantaneous and complete relief.

Being of a feeble and relaxed habit, the course of laxative medicine began to weaken her and tonics were given with good effect. The white lip and pale tongue indicated a mild course of steel, and there is no preparation so agreeable as that of the citrate given in an effervescing form. I afterwards substituted for this a mild decoction of cinchona, which, in this relaxed, flabby state of system, is far better than any form of quinine; for, being deprived of its gallic acid, it certainly loses some of the virtues which the common decoction possesses.

In replacing the uterus I enjoined the prone position, and the relief which it gave was so complete, that she was induced to overwalk herself, and thus brought on a return of the retroversion. This relapse was probably favoured by that want of tone in the soft parts to which I have before alluded, the existence of which was very distinctly shown by the effects of the prone position when continued beyond a certain time. Pain was felt behind the symphisis pubis, and other symptoms of anteversion. I have now seen this happen in several cases, and have verified the fact by examination, when the fundus has been felt forwards against the bladder, the os uteri directed into the hollow of the sacrum. I have at this moment a case in the Hospital for Women which is very similar to the above, and where, by carefully attending to her sensations, she knows pretty correctly if any displacement exists, and in what direction; she is thus able to rectify it by mere position, and, after very protracted suffering, she is now steadily improving. In her case, I have used the bark and alum injection with good effect; an increased tone of the vagina evidently giving greater support and steadiness to the uterus.

I can only attribute the return of the displacement, which occurred in so severe and painful a degree during the night of Sept. 25, to the peristaltic action of a loaded intestinal canal, when she was probably sleeping on her back; it was then that I proposed the position of the knees and elbows for a

A position like this must evidently exert a powerful influence on that of the abdominal viscera; the various coils of intestinal tube must necessarily ride up to the superior parts of the abdominal cavity, and leave the pelvic viscera entirely free from the pressure which they have hitherto exerted upon them. No posture can possibly favour the spontaneous reposition of a retroverted uterus so effec-

tually as this, unless it be the still further degree which my patient adopted of her own accord.

The effects of position in displacements of the uterus which I have shown in this and the preceding cases, are, I trust, sufficient to render the subject worthy of attention. I am far from supposing that they can be successful, or even useful, in every case, and even in the most favourable ones I am convinced they will fail unless due attention be paid to reducing, as far as possible, the weight of the superincumbent intestines, and restoring the tone of the system both by general and local treatment.

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.

The operation of lithotomy was performed by Mr. E. A. Lloyd, on a boy of the name of Charles Gosling, aged eleven, on Saturday last. The operation was completed within a minute. A nearly straight staff was employed. The grooved portion was straight, the beak only being slightly curved, and having no groove. The operation was completed with the knife, by which the first incision was made. The knife seemed to have a broad and very long blade, its cutting edge was little more than an inch in length. It appeared to answer its purpose well, as all parts of the operation were effected with the utmost facility. It is, we believe, exclusively employed by Mr. Lloyd, as is also the staff.

The stone was of small size, and composed externally of oxalate of lime. Its nature had been anticipated, as the urine, when examined microscopically before the operation, showed numerous octohedral crystals.

The boy had suffered from symptoms of stone for more than two years. He is going on very favourably.

ENCYSTED TUMOUR.

On the same day as the above Mr. Lloyd removed an encysted tumour from the posterior part of the neck of a female, Anna Dodd, aged thirty-nine. The cyst had existed twenty-three years, and was one of that class, the contents of which consist, for the most part, of epithelial cells. It had occasioned the patient considerable pain of late. She is going on favourably.

CARCINOMA OF THE LEFT MAMMA.

The breast was removed by Mr. Lloyd on Wednesday, Nov. 28.

The patient, Mary Webb, of the age of 55, a married woman, had borne and suckled one child, and had enjoyed good health through life; but, of late, she had in some degree lost strength. The tumour in the breast, the existence of which had been known for between four and five years, was of large size, increasing, and becoming more and more painful; but, as usual in such cases, the pain was only occasional. There was also a tumour, of the size of a walnut, at the margin of the axilla, similar to that in the breast, which, as well as the entire mamma, was removed.

Under the microscope, the constitution of both tumours appeared identical. There were observed numerous round and oval cells, very transparent, of small size, varying from about 1-3250 to 1-4600 of an inch, numerous large granules, and more fat globules than is common in cases of the same form of disease.

The patient has gone on without an unfavourable symptom.

Mr. Lloyd, also, on November 28, removed the left breast, on account of a carcinomatous affection, from Elizabeth Emmerton, a married woman, aged 46. She had given birth to eleven children, some of which she had suckled. The youngest is five years old. She has the catamenia at the present time. The chief part of the disease was a tumour in the outer portion of the mamma. She first observed it between five or six years ago. There were, moreover, some small hard tumours of the size of a millet grain, in different parts of the mamma. There were, also, some glands slightly enlarged, of the size of a split pea, situate between the mamma and axilla. All the diseased parts were removed, and there was very little blood lost at the operation. Examined by the microscope.—The growth exhibited numerous large and oval nucleated cells, the nuclei being also very large; here and there an elongated cell, some granular matter, and a few fat globules. In this case the cell-membrane was thinner, and the cells from two to three times larger than those in the former. Some secondary hæmorrhage occurred, but the patient is proceeding most satisfactorily.

Mr. Lloyd was asked if it was judicious to remove a carcinomatous breast, the neighbouring absorbent glands being at the time in a state of enlargement.

Mr. Lloyd replied: I do it in some cases; because I have operated in many such cases with as much success as has attended the operation in others, in which there were no diseased glands discoverable; and also because it by no means follows that the enlarged glands have undergone cancerous degeneration. Mr. Lloyd referred to several cases in illustration of the point. One of the cases was a woman of the age of seventy, in Lucas Ward, from whom he removed a very large carcinomatous breast, there being at the same time a greatly enlarged gland in the axilla, which was not interfered with. The wound healed with rapidity, and when the patient left the Hospital the enlargement of the axillary gland had nearly subsided. He also mentioned the case of another patient in Lucas Ward, from whom he removed a carcinomatous breast in a state of ulceration, there being at the time a gland in the axilla considerably enlarged, but which was left. By the time the wound had healed the enlarged gland was not to be felt, and though more than two years have elapsed, yet there has been no recurrence of the disease.

Mr. Lloyd likewise adverted to a case in which he operated in the presence of Dr. Ramadge, Mr. Hay, of Newgate-street, and the late Mr. Parker, of Oxford. In that case the cancer was in a state of ulceration, and there were several enlarged glands in the axilla. The whole mamma was removed, and also the glands, five in number. In removing the latter, the axillary artery, vein, and nerves were exposed—so deeply were the diseased glands seated; yet the patient survived several years, and died without any recurrence of dis

LONDON HOSPITAL.

PROTRACTED GONORRHŒA.

PHYMOSIS—DIVISION OF THE PREPUCE IN THE ORDINARY MANNER BY LONGITUDINAL INCISION. IRREGULAR ULCERATION OVER THE ENTIRE SURFACE OF THE GLANS PENIS—REMOVAL OF THE PREPUCE, AND RAPID RECOVERY.

A middle-aged unmarried labourer, of rather a strumous habit, came under the care of Mr. Nathaniel Ward, as an out-patient.

He had contracted about a month prior to his application at the hospital, a severe attack of gonorrhœa, followed by extensive inflammation of the prepuce, which consequently could not be drawn back from over the surface of the glans penis. He placed himself under the care of a medical man, who divided the prepuce by a longitudinal slit in the manner usually adopted.

As he did not apply to him for relief till some time after the occurrence of the phymosis, the inner surface of the prepuce had become superficially ulcerated, and secreted a fluid analogous in appearance to that coming away from the urethra.

The urethral gonorrhœa subsided under treatment in about five or six weeks after he came to the hospital; but local applications and constitutional treatment exerted but a slight and only temporary benefit on the morbid action set up in the prepuce, which continued for two or three months in nearly the same condition, as immediately after it had been longitudinally divided.

In consequence of this protracted discharge from its surface, and it being impossible to keep the two folds, from contact with the glans, the surface of the latter very soon took on a similar diseased condition, and in a month became irregularly ulcerated over its entire surface, here and there assuming a greyish, sloughy appearance, and discharging an unhealthy sanious and puruleut fluid.

The only evident means of effecting a cure being the entire removal of the prepuce, it was done in the following manner, viz.:—Having been drawn forward over the glans penis, and transfixed in the middle by a sharp pointed bistoury, immediately beyond the termination of the original incision, the two halves were successively divided by two concave sweeps, in a line with the convexity of the glands.

Sutures were applied to bring together the inner and outer membranes and warm water dressing used.

At the end of a fortnight cicatrisation had taken place, and in about a week after, the glans penis had assumed, by the aid of a little astringent lotion, and frequent washing, its natural appearance.

Mr. Ward observed, in reference to this case, that it formed a very practical illustration of the advantage of complete removal of the prepuce over its more usual longitudinal division.

He recommended a similar proceeding also in

of the two curved incisions, after the bistoury transfixed the prepuce, a clean unjagged circumference was left.

In reference to the removal of the inner membrane, which always requires a second division, owing to its comparative inelasticity, and from its generally embracing the glands so tightly that it cannot be brought forward in the first incisions, so as to divide it on a level with the external membrane, Mr. Ward, in this case, incised it longitudinally by a pair of scissors, as far as the corona glandis, and then swept off the two lateral folds, so to bring the membrane in the same line with that of the divided external membrane.

FATTY TUMOURS BENEATH THE MUCOUS MEMBRANE OF THE CHEEKS.

An unhealthy child came under Mr. Ward's care as an out-patient, August 14, 1849, with two tumours on the inside of the cheeks.

They were equal in size, and about the dimensions of a small walnut, with the long axis from before backwards, placed in the situation of Steno's duct. when the mouth was open, they protruded into that cavity between the back part of the molar arches.

The membrane over them was tense and shining, and the swellings to the eye and to the touch gave the idea of circumscribed collections of fluid, which, from their relation to the duct of the parotid gland, were diagnosed, as having some connexion probably with a diseased condition of that canal.

On puncturing them, however, the turned out to be irregularly lobulated masses of fat, and were easily removed by a longitudinal incision.

The case was interesting, merely on account of the rarity of situation of the fatty tumours.

KING'S COLLEGE HOSPITAL.

On Saturday last Mr. Fergusson performed two important operations.

The first was excision of the eye-ball. The patient, a middle-aged man, had suffered for twelve years with disease of the eye, which had been originally caused by a punctured wound from a shoemaker's awl; the consequence was, that the sight of the eye was lost. Latterly he had suffered severe pain in the orbit and forehead, and the eye had become very prominent, and a dark substance was observed protruding into the anterior chamber. These symptoms led to the suspicion of some malignant tumour, deeply seated in the orbit, and involving the eye; and as the patient suffered very much, and in other respects was perfectly healthy, Mr. Fergusson determined to remove the morbid mass. The operation was performed in the following manner:—An incision through the skin was made at the outer angle of the orbit, and these were slightly dissected away; the knife was then carried deeply around the ball of the eye, into the orbit, and by means of a

hooked pair of forceps, it was held up and its posterior connects were cut away; by this means the eye was removed. On looking at the back of the orbit no tumour was found; the hemorrhage was but slight, and easily restrained by a pad lint.

On cutting into the eye it was found completely disorganised, and its interior changed into a dark looking morbid deposit, having an appearance not unlike that of a melanotic transformation.

The next patient operated upon was suffering from a bad stricture of the urethra, complicated with perinæal and scrotal fistulæ. He had laboured under stricture for many years; had neglected himself fistulæ had formed, through which nearly all the urine came away. He had not had a catheter passed for a long time previous to his coming into the Hospital, and, on admission, Mr. Fergusson discovered that he had a cartilaginous stricture at the bulb, through which it was impossible to pass any instrument. It was, therefore, determined to operate upon him by the perinæal section, which was performed in the following manner:—

The patient was placed fully under the influence of chloroform, and a small catheter was attempted to be introduced, but, notwithstanding the use of great care, it was found useless to endeavour to pass it further than the face of the obstruction. The patient was then tied up in the position for lithotomy, and, the catheter being retained, a free incision was made in the middle of the perinæum through the hardened tissues, until the point of the knife impinged upon the catheter. The urethra was then opened, and the stricture was freely divided its whole length towards the bladder. The catheter was then changed for a larger one, which, after another incision or two, was carried along into the bladder, and there retained. There was not so much difficulty as usual in this instance; for this operation, in those cases which really require it must be considered as one of the most difficult in the whole range of surgery; nevertheless, now give more decided relief to the patient, and there is very little hazard when it is performed in the cautious and skilful manner, practised by Mr. Fergusson. This gentleman made some excellent practical remarks afterwards, with reference to this proceeding, which we have not time at present to notice; but, as he promised the pupils, he would, at a future time, make it the subject of a Clinical Lecture, we shall take that opportunity of giving our readers a report of the same.

NORTH STAFFORD INFIRMARY.

Thomas Colclough, aged 17, collier, admitted July 6, 1849, under the care of Mr. Ball. He is a robust, healthy youth, sanguine temperament, and of temperate and regular habits.

At twelve o'clock on the same day, when working in a coal-pit, was suddenly struck down by a blow from a brick which fell from the shaft above on his head. He was taken up insensible and brought to the Infirmary. On his admission he presented the following symptoms:—

A large wound on the scalp, extending from near the crown to the back part of the head, about two inches in length. On examination a fracture, with depression, apparently involving the parietal and occipital bones, distinctly felt. His pupils are equally dilated, and not affected by light. He is quite insensible, unless roused, which is done with difficulty, and then relapses instantly into the same state. He continually shifts his head from side to side, and moves his limbs uneasily. His sensation is impaired, his surface cold, his pulse labouring and slow.

Head to be shaved, and warmth to be applied to the surface and feet.

Towards evening his water was drawn off, rather ammoniacal, but not more than a pint in quantity.

℞ Hyd. chlorid. gr. v. h. s. sum.

℞ Ol. Ricini, ℥j.; decoct. hordei oj. fiat enema; statim utendum.

July 7.—Has had two motions, and has passed water several times during the night. Pulse more full, but still laboured. Venesectio ad ℥xx. consultation being called, it was decided to elevate or remove a portion of bone, according as was found necessary. The lacerated wound was T-shaped was enlarged in each direction, the seat of fracture being laid bare. The upper portion of the occipital bone was found projecting, having been pushed outward by the depression of the right parietal bone that portion forming the angle of the sagittal and lambdoidal suture being fractured for about two inches. The detached pieces, which altogether formed a surface of two inches by three, were removed, and the edges of the wound brought together by a suture, and wet lint applied.

Since the operation has been more sensible, but still continues very uneasy. He answers questions readily, and appears less confused. He can tell when anything is placed before his eyes; but cannot distinguish one object from another.

3 p.m.—Venesectio ad ℥xvi., the countenance being flushed, and the pulse more full and labouring. The appearance of the blood, from the recent bleeding, does not indicate inflammation. Passes water freely, and has had another motion.

11 p.m.—Venesectio ad ℥x., the pulse being again inclined to become full.

As his water had not been passed since 3 p.m., a catheter was introduced; but not more than about half an ounce of water came away.

8th.—Has passed rather a restless night; has made water three times; appears very drowsy pupils act slightly; he is very thirsty, asks when he requires drink; surface hotter than natural; head not more so than other parts.

℞ Haust. sennæ ℥iss. stat. s.

2 p.m.—Bowels not opened by medicine. Enema calidæ aquæ.

8 p.m.—Has had three motions; appears much the same in all respects.

9th.—Has passed a restless night; motions and water come away involuntarily. Appears more drowsy, and altogether less rational.

10th.—Much in the same state as on the preceding day; wound dressed; with the exception of a slight fœtor, its appearance is healthy.

11th.—Not so well, all the bad symptoms being aggravated. He is roused with difficulty He has no power over his sphincters. His tongue is dry, and his skin rather hotter than on the preceding day. Bowels opened once. Takes gruel every quarter of an hour, with apparent relish.

℞ Tinct. opii. m. xx.; h. s. sum.

12th.—Has passed a better night, and appears altogether better this morning. His motions and urine are no longer passed involuntarily. His pulse about 80, and less frequent than it has been since the accident. Broth ordered and the gruel continued.

13th.—Has passed rather a less quiet night, but has slept since daylight. He continues steadily to improve.

10 p.m.—Complains of intense pain in the head.

℞ Tinct. opii. m. xx.

From this time he continued steadily to improve, complaining occasionally of headache and continually of dimness of sight up to the end of September, when a piece of bone, about half an inch square, which had become carious, came away, and he was discharged cured. October 15, the wound being entirely healed. The dimness of vision had to a great extent left him, and he was in all respects, with this one exception, as well as before the accident. He has since visited the Infirmary as an out-patient, and was to resume his occupation this week.

Nov. 14, 1849.

Veno Beno.—A paragraph has appeared in some papers stating, that a substance called Veno beno, the leaf of a tree or climbing plant, is used as adding greatly to the strength and flavour of tea. The plant is indigenous in the Indian Archipelago, and naturalised in India. Lindley describes it as producing intoxicating effects, stimulating powerfully the salivary glands and digestive organs, and diminishing perspiration. In India it is used as a tonic and stomachic. It has a pungent aroma, and is of a warm stimulating nature.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

POPULAR LABORATORIES.

M. Dumas, Minister of Commerce, following up the course which he has commenced so well, proposes adding another *Professorship* at the "Arts and Trades," to those already existing in that excellent Institution for the instruction and improvement of the working classes.

M. Payen now delivers a course of lectures on Chemistry, as applied to the arts and industry; but this has appeared insufficient to M. Dumas, and a course of operative chemistry for the workmen will soon be opened, at which public demonstrations on a grand scale, as at the Sorbonne, will be given. It is said, that the beautiful new chapel of the Conservatory is to be converted into an immense laboratory for this purpose; but its stained windows, lofty columns, and narrow aisles seem little suited to such a destination. Many of the gratuitous courses delivered at the public Institutions here, include, I perceive, lectures on hygiene. This is an example well worthy of imitation, for in nothing are the working classes of every country more ignorant than in matters connected with the preservation of their health. Science, however, is rendered almost useless from the deplorable state of the drainage, which is infinitely worse throughout two-thirds of Paris than it is in the worst quarters of London. With a permanent source of disease beneath the soil, it is all but superfluous to teach the lower classes how to avoid maladies, the causes of which are beyond their reach.

M. Dumas has also evinced his desire to improve the condition of the people by the introduction of a law for the establishment of "retiring funds" for aged persons. This may be almost considered a measure of hygiene, because whatever improves the material comforts of the poor adds considerably to the sum of public health. Under the new law a national bank is to be created for the reception of sums varying from 10 francs to 10 centimes at a time. The annuity will not commence until the individual has reached the age of fifty; it can never exceed 24*l*., and its amount is to be calculated according to a scale appended to the law.

THE POLARISCOPE.

There is no instrument known here under the name of "Polariscope," but your correspondent evidently alludes to the apparatus employed by M. Biot for observing the rotatory power of certain fluids. This apparatus has been manufactured expressly for M. Biot by Bianchi, and was presented to the Academy of Sciences by M. Biot, on the 13th September, 1847. It is figured in the last edition of M. Pouillet's Treatise on Physics, Vol. II., p. 435. As you have already given a general description of the instrument, it is unnecessary to repeat one here; but it may be observed, that the ordinary apparatus can be adapted to the examination of fluids, by the slight addition of small tubes in which these fluids are placed. It is not, however, enough to have an apparatus. One must know how to use it. Hence, perhaps, the following remarks, published some time ago by M. Biot, may be useful.

We suppose, of course, the *ensemble* of the apparatus sufficiently known, but it may be well to give a general idea of it. A ray of light is reflected from glass, at an angle of about 35°30; and the mere fact of its being reflected renders it polarised. The polarized ray is thrown into a tube furnished with transverse plates, and thence falls perpendicularly on the surface of a double refracting prism, which is placed in the centre of a graduated circle, and which moves on an alhidade or transom. When the observer desires to examine liquids, small metal or glass tubes, closed at either end by glass plates, thin and parallel to each other, and containing the fluid to be examined, are placed in the line of traject of the polarised ray, before it arrives at the prism, the index of which marks zero. Now, if the fluid have no effect on the polarised ray, the extraordinary image is absent; if it have an effect, the

image is visible, and, on turning the transom of the prism to the right or left we arrive at a certain point where the image disappears.

The arc contained between this point and zero gives the angle of deviation for the red rays at least.

The principal parts of the apparatus are "the mirror, prism, and tubes."

The mirror, formed of black glass, is intended to reflect a ray of light at an angle of 35°30, and project it into the tube. By adapting a screw to the bar which supports the mirror it is easy to give it the proper inclination.

The light which is transmitted from the clouds is much preferable to that of the sun, and it will be well, when the apparatus has been arranged, to interpose something to prevent the sun's rays from falling on the mirror at the same time with those transmitted through the atmosphere.

Another precaution indispensable is, that the observer, who is to analyze the polarized ray, must not have his eyes exposed to the light. The brightness of the latter would prevent him seizing many of the delicate effects of polarization. Hence, the tube containing the reflected ray, the prism which analyzes it, and the operator, must be in a dark chamber; in fact, the mirror is the only part of the apparatus that should be exposed to the light. Still, the observer must have some light to read off the figures on the arc, and to obtain this M. Biot recommends the use of a separate door close to the operator, who can open and shut it without moving from his seat.

The prism must be of such a kind, that a ray of natural light, refracted by it, be resolved into two fasciculi. M. Biot points out the way of obtaining such prisms, and pronounces absolutely against the use of rock crystal or tourmaline. Iceland spar is the only substance that will answer.

As to the manner of regulating the apparatus, M. Biot gives the following directions:—"The first object is to give the reflected ray the greatest degree of polarization that it is capable of receiving. This is done by bringing the mirror to the point which the instrument-maker has marked theoretically: this done, the graduated circle that supports the prism is inclined, until its plane becomes perfectly perpendicular to the axis of the tube containing the reflected ray.

The observer now retires to the dark cabinet, and turns the transom until the extraordinary image becomes either absent or as feeble as possible. This position being well fixed, an assistant turns the screw which regulates the mirror, so as to change its plane slightly about the theoretical point, until the observer meets with the position in which the ray is most completely polarized, as shown by the disappearance of the image. The mirror is then fixed in this position, the side-door is opened to give a little light, and the index is brought to zero. The door is now closed, and the prism made to revolve until the image disappear again. Lastly, a new trial having shown that the mirror is properly placed, the prism is fixed on the transom by means of a screw If it were possible to conduct the preceding operations in a perfectly rigorous manner, the apparatus, thus regulated, would bring the principal section of the prism in the plane of reflection when the index marked zero; and the zero of the primary polarization would coincide with that of the circle. But this never occurs perfectly. Hence the observer must turn the index successively to the right and left, marking the places where the image is most feeble, and the limits will comprehend the true zero.

The "tubes" are of two kinds; one of tinned copper; the other of glass. The tubes are closed at both extremities with plates of glass, polished, and parallel to each other, and luted on stoppers, which latter must not possess any polarizing power. The apparatus which supports them must be fixed. Indeed, M. Biot recommends that all parts of the apparatus be as permanent as possible, in order to avoid those perpetual verifications which the least change of place would render necessary. The apparatus of M. Biot is sold by M. Bianchi, of the Rue de Sorbonne, and costs 24l. From the price, and the difficulty of managing, I fear that it is only suited to Professors of Chemistry, &c., and is beyond the reach of students.

TREATMENT OF TYPHOID FEVER BY COLD.

M. Wanner pretends not only to cure this fever, but to cut it short in a few days by the methodic administration of cold from the commencement of the disease, and without interruption. Every one or two minutes the patient swallows a small bit of ice, so as to furnish about a glass of fluid per hour. This is aided by a demi-lavement of cold water every six hours, and every second day a bath at 27° Reaumur.

The author affirms that all the patients treated in this way during the last three years, and they have been numerous, recovered.

SELECTIONS FROM FOREIGN JOURNALS.

REGENERATION OF THE SCIATIC NERVE.

The complete regeneration of nervous tissue has been asserted by Fontana, Tiedemann, Flourens, and others. But in almost all cases the proofs of absolute regeneration have been in some point defective. An observation on this subject by M. Brown Séquard possesses some interest. On the 15th August, 1848, the sciatic nerve of a guinea pig was cut, and, in order to avoid all injuries to the paralyzed limb, the animal was enclosed in a cage, carefully wadded with cotton wool. A month after the operation sensibility began to return. Two months afterwards the animal began to regain the power of motion. Six months afterwards sensibility was almost entirely restored; the animal moved the limb tolerably well. In nine months the sensibility and mobility were perfectly restored. In September, 1849, the animal was exhibited at the Société de Biologie, and the nervous endowments were pronounced to be quite perfect. A few days later the animal was killed. In cutting through the nerve, above the point of section, twitches of the muscles were observed. The point where the nerve had been cut was discernible only by the adherence at that point of the muscular fibres to the neurilema, and by the previously noted position of a large branch. There was no swelling or other indication. Examined microscopically by MM. Lebert and Brown-Séquard, the nerve tubules appeared absolutely natural.—*Gaz. Méd.*, Nov. 10.

LESIONS OF NUTRITION AFTER SECTION OF THE SCIATIC NERVE.

The bruises, losses of nails, ulcerations, &c., observed by some experimenters after section of the sciatic nerve, are stated by M. Brown-Séquard to be merely the effects of mechanical injuries sustained by the paralyzed limb When the animal experimented upon was enclosed in a padded cage, no such lesion of nutrition followed.—*Gaz. Méd.*, Nov. 10.

COMPOSITION OF THE BLOOD, EVACUATIONS, AND URINE OF CHOLERA.

The following is an analysis of a paper by M. Becquerel, in the *Archives Générales*:—

1. In 6 vomited fluids the re action was acid 4 times; neutral, twice. The specific gravity varied from 1006 to 1021. The solids, in the filtered liquid, varied from 6·37 to 54·7 parts per 1000. The albumen was not weighable in two cases; in 4 it varied from 5·11 to 31·5 parts per 1000. The chloride of sodium ranged from 2 35 to 6·75. The other salts and the non-albuminous organic matters varied from 4 to 24 parts per 1000. The average of the whole was, water, 972 9; albumen, 13; chloride of sodium 4·93; other organic matter and salts, 9·17 in 1000 parts. The flaky matters, separated by the filter, seemed to bear a general ratio to the amount of dissolved solids.

2. In four stools the re-action was always alkaline; the specific gravity varied from 1004 to 1011; the solids, from 8 to 15; the albumen, not weighable in two cases, reached in the others 3·22 and 4·51 parts per 1000. The chloride of sodium in one not reckoned, in the others varied from 3 to 7. The average of the four was—water, 987·11; albumen, 3·86; chloride of sodium, 5·58; other salts and organic matter, 3·45, in 1000 parts.

3. In four specimens of serum taken from young male adults, from 25 to 35 years of age, in the stage of re-action, the specific gravity varied from 1035 to 1044; the solids varied from 98·21 to 113·40; the albumen, (purified,) from 48·21 to 81·66; the chloride of sodium, in three cases, from 7·38 to 12·26; the fatty matters, in two cases, 4·23 and 4·70; the extractive matters reached the astonishing amount of from 28·74 to 38·40 in the 1000 parts. The average of the four was—water, 892·6; albumen, 65·04; fatty matters, 4·46; extractives and some salts, 32·9; chloride of sodium, 9·45.

4. In two specimens of blood, taken in the cold stage, from men aged 30 and 35 years, the composition was as follows:—The first case, a man bled the morning of his death, from severe cholera with cerebral congestion, the pulse strong and hard, the skin yet cold and cyanosed—sp. gr. 1074·1; water, 722 52; red particles, 189·60; fibrine, 1·88; pure albumen, 51·80; chloride of sodium, 6·61; other salts, fatty and extractive matters, 27·59. In this case the fibrine was collected with great difficulty; left to itself, the blood hardly coagulated and separated scarcely any serum. The second case, a man bled the morning of his death; exact symptoms not given; specific gravity, 1075; water, 754·95; red particles, 160·2; fibrine, 6·5; pure albumen, 69·35: chloride of sodium and other salts, fats, and extractives, 20. Becquerel is not able to account for the increase of the fibrine in this last case. The observations on the urine are limited to the recognition of albumen; from a very small number of cases, Becquerel determines that, in some cases, there is no albumen in the urine, in others a greater or less quantity.

M. Becquerel's results agree generally with those obtained in this country. The chief points of novelty are the enormous increase of extractive and fatty matters in cholera blood, and the diminution of the albumen. With regard to the flocculi of the stools, Becquerel regards them as coagulated albumen, but he does not give the grounds on which he bases this opinion. He thinks that the albumen dissolved in the cholera fluid diminishes gradually from the outset to the intense disease.—The quantity of albumen noted in some of the vomited fluids is much greater than has, we believe, been noted here.—(*Archiv. Gén.*, Oct.)

THE SWEATING SICKNESS IN FRANCE.

With regard to the sweating sickness which has shown itself in so many parts of France simultaneously with the cholera, MM. Lachaise and Dufay have formed the following opinions:—1. The sweating sickness appearing simultaneously with cholera, may be considered as a less intense or as an abortive condition of this disease. 2. Directly sweating sickness is seen during an epidemic of cholera, it may be predicted that the cholera will be slight and of short duration. 3. When the sweat and cholerine advance simultaneously, and pass one into the other, it is advisable to attempt to bring on the sweat, and dangerous to allow the increase of cholerine, which passes often into cholera. (*Arch. Gen.*, Sept., p. 101.)

ARSENIC IN AGUE.

M. Boudin, Physician-General at the Military Hospital at Roule, has reported most favourably of the effects of arsenic in marsh fevers. During five years quinine has never been used—no accident has resulted from the employment of the arsenic during eight years. The patients have been more rapidly cured than even by disulphate of quinine. (*Arch. Gen.*, Sept.)

AUGMENTATION OF FIBRINE BY HEAT.

M. Marchal (de Calvi) has presented a report to the Academie des Sciences on this subject. The following are his conclusions:—1. The elevation of temperature determines an increase in the fibrine of the blood. 2. The increase of fibrine in inflammations is partly due to the elevation of the temperature. 3. Fibrine is only albumen coagulated "molecularly" under the influence of heat. (*Arch. Gen*, Sept., p. 108.)

CASE OF A PULMONARY CAVITY OPENING EXTERNALLY.

By Dr. POLLET.

Cases of this nature are sufficiently rare, so that we shall be excused for narrowly scrutinizing this case, brought forward by M. Pollet, as to whether it actually is such as the title bears. An abstract of the case will satisfy us on that point.

The subject of the remarks was a girl of a very marked scrofulous constitution, about twenty years old. She has, as our Author remarks, all the rational and physical symptoms of phthisis in an advanced degree. About three months before death, a tumour, about the size of a pigeon's egg, appeared an inch beneath and exterior to the left breast; it increased gradually, and finally attained the size of the fist. From the commencement it fluctuated, and subsided under gentle and uniform pressure, afterwards recovering its ordinary bulk; movement of elevation and of subsidence, obvious to the eye and corresponding with those of inspiration and expiration, were noticed in it. This accumulation burst in a paroxysm of coughing; and a considerable quantity of pus escaped from it. The patient was visited by M. Pollet the subsequent day, who ascertained that the opening from which the pus had issued was circular, and passed beyond the body of a rib. The opening was exactly like that made by the crown of the trepan. A style passed without any resistance being offered, three fingers breadth. The matter which escaped for several days afterwards by that opening resembled that which hectic patients expectorate; besides, a breath was very distinctly perceptible at each respiratory movement. The patient expired four days after the abscess had burst, but no autopsy was permitted.

Such is the narrative of the case. With regard to it, we feel the same difficulties as the worthy reporter of the case to the Medical Society of Emulation in Western Flanders, Dr. Joseph Ossieur. The defined form of the perforation, so completely circular, of a rib, without ulceration or perforation, leads to the belief that it arose from a tubercle seated in the centre of the bone, and that it was not formed by the escape of pus from a cavity of the lung. In the cases hitherto described, of cavities opening externally, it has not been by the ribs, but by the intercostal spaces, that the pus appeared, the reason of which it is unnecessary to render. The Author, it is true, asserts, that the tumour was fluctuating from the beginning, and subsided on pressure. But these terms, "from the beginning," are actually merely equivalent to those "from the time when the tumour was perceived." And, indeed, the language in the narrative gives faith to that remark; for it had already the magnitude of an egg. What inference could then be drawn? That the tumour, at a certain period of its progress, had communicated with the pleura, but no more; and this circumstance does not point out to anything but a simple abscess in the walls of the thorax, by the tubercular destruction of a rib.

Nevertheless, did the fistulous communication with the internal organs extend beyond the sac of the pleura? Did it extend to the interior of the pulmonic tissue, which had become cavernous? On such a supposition, we must admit, with M. Ossieur, that a superficial vomica was present, exactly on the level with the osseous tubercle, and that a communication had been formed between these two purulent caverns? One circumstance is undoubtedly in favour of such an hypothesis,—the statement, to wit, of the author, that the matter thrown off by the external aperture was similar to that of phthisical sputa. We willingly give him credit for this fact on his own observation, but not without regret at his not having entered into more specific details on the stethoscopic signs. It is the only way in which the deficiency of the autopsy could have been supplied. The only sign which he narrates, the *bruit de soufflet*, ascertained after the opening of the abscess extenally, is not of a very clear character, especially apart from other signs by which it ought to be disclosed, if there had existed a pulmonary cavity communicating outwards.—*Ann. de la Société Médicale d'Emulation de la Flandre Occidentale.*

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, Wm. S. Orr and Co.

THE MEDICAL TIMES.

SATURDAY, DECEMBER 8, 1849.

The Council of the College of Surgeons have confirmed, by a large majority, the resolution passed at a previous meeting, giving power to the Council to apply to the Crown for a modification of the Charter of 1843. The injustice of that Charter is then, we rejoice to say, at last acknowledged by the Council. For seven years it has been felt by the members. Up to the present moment, no intimation has been afforded to the Members of the College of the change in their position the proposed new Charter is to effect. It is the duty of the Council to inform the Members of the principal details of the proposed alterations, previous to making application to the Crown for a new Charter. This is the only mode of avoiding those reproaches and dissensions that were consequent on the secret negotiations by which the former Charter was obtained. But, we believe the matter rests with the Profession. If they are up and stirring, the Government cannot recommend the Crown to grant another Charter to the College, without the members (even more deeply interested than the Council itself) being acquainted with its provisions. Especially, when the Government remembers that the very act of applying for another Charter is an acknowledgment on the part of the Council, that for seven years they have inflicted a grievous injury on the great body of the members of the College.

We trust no opposition, to what we anticipated to be the liberal intentions of the Council, will be offered by such of the Fellows as have obtained their rank by examination. They must recollect that they gained their present position at a time when they knew that the almost unanimous voice of the Members of the College was raised against the Charter of 1843. Moreover, they will retain a substantial benefit, for their Fellowship diploma will bear a date anterior to those granted under the new Charter; the date of the Fellowship diploma regulating the period when its possessor is entitled to look forward to a seat in the College Council.

We cannot conclude without expressing to the Council our conviction,—and we speak from a long and intimate acquaintance with the wants and wishes of the Members of the College,—that a supplemental Charter, in which the Fellowship, without examination, is conferred only on Members of twenty years' standing, would simply stir afresh the embers of discord; while it would render some discontented, it would altogether fail to conciliate the great body. If the man who obtained the Membership at twenty-two is not deserving the Fellowship at thirty-five, we think, without taking any credit to ourselves for the gift of prophecy, we may predict that age will never render him worthy of that honour.

THE LATE MR. DIXON, OF WORTHING.

The honours of the Obituary Notice in a special Article have hitherto been reserved, in our Medical Journals, too exclusively for those members of the Profession who have filled the high places in the Corporate Bodies, or who, as Physicians and Surgeons to the great Hospitals, have reaped the profits as well as the honours of Metropolitan Practice. But we are of opinion that the more humble career of the middle-class of Practitioners would, in many instances, afford a theme as worthy, and be even more instructive and exemplary, by the virtues of manly simplicity, perseverance, single-mindedness, charity, and patient endurance of neglect or oppression, which are called into action during the avocations and struggles of the Country Practitioner. Amongst the members of this class, also, there have not been wanting men who have added lustre to their Profession by the devotion of their abilities and leisure-intervals to the advancement of some allied Natural Science. The young Practitioner, in whose memory the principles of the fundamental sciences of his Profession are fresh, and with leisure which may never recur at a later period, should bear in mind that it was a course of experiments in Comparative Physiology which led Jenner to the discovery of the simple mode of extirpating or controlling of a desolating pestilence—a discovery which has immortalised the name of the country Practitioner of Berkeley.

The successful accomplishment of the operation of tying the internal iliac artery was reserved for a Practitioner of the same class in a remote Colony, whose contributions to the physiology of the blood, respiration, and to the rational treatment of the yellow fever, and other formidable epidemics, exemplify an original and masculine frame of mind akin to that of Jenner.

Results of such importance are not, indeed, to be expected as the unfailing reward of scientific research; but the habits of observation and reflection which have led to them in the cases of Jenner and Stevens, will keep the mind in a healthy and vigorous state, and best fit it for working out the problems of disease by the bed-side. Every accession to Science reflects credit upon the Profession to which such contributor may belong. It is in this relation chiefly that we have deemed the memory of a lately deceased Surgeon, at Worthing, in Sussex, to merit the following tributary record.

Mr. Frederic Dixon was educated at Eton, and manifesting a strong predilection for Natural History and Anatomy, he was articled to Mr. Foster, the Senior Surgeon to Guy's Hospital, under whose colleague, Sir Astley Cooper, his professional education was completed, with a view to his practising the higher department of his Profession as a "Pure Surgeon." From the esteem in which his personal character, abilities, and assiduous habits of study were held by his teachers, as well as by his contemporaries and fellow-pupils, Green, Callaway, and Key, there is little doubt but that, like

them, he would have attained eminent rank in his Profession had he devoted himself to Metropolitan practice. Preferring, however, the calm enjoyments of a country residence, and that share of philosophic leisure which is commonly sacrificed in the struggles of a professional career in London, Mr. Dixon retired early to reside on some property which he possessed at Worthing; in which town and its vicinity he continued to practise up to the period of his fatal illness, in September last. His early tastes and habits of observation led him to study the Geology, and to collect the fossils of the parts of Sussex to which he was led by his professional avocations; and the peculiar skill with which he worked out the organic remains from their native matrix made his Collection remarkable for the rarity, beauty, and perfect condition of the specimens, especially of those from the chalk-pits of the Vale of Arun, and from the eocene beds at Bracklesham.

The number of new facts and valuable illustrations of the Paleontology, or ancient extinct animals, of the different geological formations, thus studied by Mr. Dixon, determined him to publish them, with figures of the undescribed fossils by the best artists whose skill he could command. He had made considerable progress in this valuable work at the period of his lamented decease; but, as an Author, he was known only by a few papers, characteristic, however, of his elegant and classical mind, on the Historical Antiquities of his neighbourhood, published in the Journal of the Sussex Archæological Society.

Availing himself of that assistance, in the determination of his fossil specimens, which the Authorities in the different classes of Organic Remains are ever ready to afford, he might himself have described his own rare and unique specimens, simply acknowledging the sources of their determinations. He might thus have appeared as the Author of "Original Memoirs" in the "Philosophical Transactions," had he been troubled by that restless vanity which makes some men clamorous for "Royal Medals," and ready to avail themselves of any prop by which their name may be lifted up to the world's gaze. But it was repugnant to the better regulated mind and feelings of Mr. Dixon, to assume the character of "Scientific Author" on such grounds. And his procedure, in reference to his projected Work, was eminently characteristic of his upright principles and single-mindedness. His desire was simply to impart to his brother geologists, in the best way, without regard to self, whatever knowledge might be afforded by the specimens which he had collected. He therefore requested the Authorities, whose aid he found requisite to determine a doubtful specimen, or to confirm his opinions of its nature, to furnish also the descriptions of such fossils, to be published under their names. Thus, the Appendix to his Work was designed to contain the description of the Fossil Corals, by Mr. Lonsdale, F.G.S.; that of the Fossil Shells, by Mr. Sowerby; that of the Echinoderms and Crustacea, by Professor Edward Forbes; that of the Fossil Fishes, by Sir Philip Egerton, M.P.; and that of the Fossil Reptiles and Mammals, by Professor Owen. Mr. Dixon reserved to himself that part of his Work which he could truly call his own—his Observations on the Geological Structure of his County, and the description of the localities, and the narration of other circumstances connected with the discovery of his fossil specimens.

Mr. Dixon had expended large sums in the numerous beautiful plates engraved for the illustration of his Work, the completion and publication of which, by some competent friend, are looked forward to with much interest by geologists, both at home and abroad.

Having occasion to visit London, to direct some improvements in the drainage of the house of one of his tenants, in the month of August last, Mr. Dixon was seized with diarrhœa on his return home; but the prompt treatment to which he subjected himself prevented it going further than an early stage of spasmodic cholera. The attack left him greatly debilitated; and premature exertion induced relapse, with modified symptoms, which ultimately degenerated into autumnal dysentery, and carried him off on the 27th September, 1849, aged 50.

He died, deeply regretted by all classes o the society in which he had mingled, as a friend or professional adviser. He had been mainly instrumental in the establishment of the Dispensary at Worthing; and the poor flocked from every hamlet, to witness and lament th passage of the mortal remains of their friend and adviser to their final resting place at his native village.

MISSTATEMENTS RESPECTING THE CONFERENCE AT THE HANOVER-SQUARE ROOMS.

We are enabled to refute numerous misstatements in reference to the proceedings of the Conference Meeting recently held at the Hanover-square Rooms, which appeared last week in the Leading Article of a Contemporary Journal. The Article commences with an eulogy of Mr. Bottomley, whom it describes as an "eminent operative surgeon." We have no desire to find fault with the gods whom our Contemporary might please to set up for his particular idolatry, and we shall at once proceed to place before our readers the particular misstatements, with their refutation, *seriatim* :—

1st. Dr. Webster is stated to have "supported the views of Mr. Bottomley." On the contrary, Dr. Webster contended warmly against the possibility of converting the College of Surgeons into a College for the whole Profession, and adhered to the principle of a new Incorporation; thus directly antagonising the sentiments of Mr. Bottomley.

2nd. It is said, that "Mr. Cartwright, of Oswestry, although his name was advertised in one of the resolutions, was not at the meeting." If this sentence be intended to convey a covert insinuation against the Council of the National Institute, it falls to the ground, for we now inform our Contemporary, that Mr. Cartwright's name was placed upon the Deputation at Mr. Bottomley's especial request; and the suggestion was assented to by the Conference in courtesy to Mr. Bottomley.

3rd. In Mr. Bottomley's letter, which forms a portion of the leading article, it is averred, that a motion that the resolution that they (the propositions) should be adopted by the meeting was formally made by Mr. Dalrymple, of Norwich." Mr. Dalrymple made some very just observations prior to the propositions having been read, or before it was known that Mr. Bottomley had them in his pocket; but he certainly did not move their adoption.

4th. It is stated, in the same letter, that the motion adopting the resolutions "was carried without a dissentient voice." Again incorrect. The propositions, as read by Mr. Bottomley and published by our Contemporary, were strongly objected to on many points, and the question was put, only on the condition that the propositions should be referred to a Committee, with power to amend them in accordance with the views of the Conference; and the resolution distinctly stated, that the "substance" of the memoranda alone should be submitted to the College of Surgeons. It was especially urged, that the propositions contained matters of opinion unsuitable for such a document.

5th. It is remarked, that "the seconding of a motion for their approval, *particularly the first proposition* by Mr. Ancell, is a most extraordinary paradox!" The wonder with which our Contemporary appears to be transfixed will be somewhat abated when he learns that this first proposition was the chief one that the Deputation were requested to strike out,—an alteration assented to even by Mr. Bottomley.

The only other gentleman connected with the Conference, whose name is mentioned in the article is that of Mr. Ross, who requires from us no justification.

It is thus very clear that although Mr. Bottomley may be an "eminent surgeon," he is not blessed with a peculiarly retentive memory; and this the world might never have discovered, if circumstances, which we will not stop to analyze, had not prompted him to assume the office of reporter for the press; and that apparently for no other purpose than magnifying his own self-importance before the Profession. We congratulate him on his success.

It would seem that the National Institute agreed to the substance of Mr. Bottomley's resolutions, in order to secure unity of action; and, in the event of the Council of the College refusing to accede to Mr. Bottomley's scheme, that they might go to the Secretary of State with increased strength for the establishment of an independent College. In this way the deliberations of the Conference at the College of Physicians might have received a new impulse and support from the proceedings of the gentlemen meeting at the Hanover-square Rooms. Mr. Bottomley's propositions go to this extent.

FEMALE EMIGRATION.

Most of our readers have probably seen in the columns of one or more of our daily Contemporaries a letter from Mr. Sidney Herbert, on the melancholy subject of the sufferings of the poor needlewomen. After pointing out the hopelessness of looking for permanent good from casual alms, and dwelling at considerable length on the present "fierce competition between money and money, between man and man," the Writer comments on the disproportion of the sexes

here and in the Australian Colonies, and says, that "a redress of this inequality is the crying want of society there, just as the redress of the opposite inequality in this country is the necessity here." He proposes—

"That a fund be forthwith raised to assist distressed females to emigrate.

"That this fund be administered by a Committee, with the assistance of the local clergy and the religious societies in the districts."

We are sure that our readers will be as ready as we are ourselves to co-operate with Mr. Sidney Herbert in carrying his benevolent plan into effect. We are far, indeed, from wishing to detract from the praise which he has awarded to the working clergy and the religious societies; but we venture to say, that the most intimate knowledge of the condition and wants of the poor will be found among the members of that Profession to which we ourselves are proud to belong; and we have no hesitation in saying, that if the assistance of Medical Men be not secured, the sphere of the proposed Committee's usefulness will not be so extensive as it ought to be.

MODE OF DETECTING CHLOROFORM IN THE BLOOD.

The fatal accidents which occasionally follow the use of chloroform, and the possibility of this substance being employed for criminal purposes, render it necessary to examine it in a medico-legal point of view.

When exposed to a red heat it is decomposed into chlorine and hydrochloric acid, and this principle enables us to detect it in the blood. Thirty scruples of this fluid at least will be required to operate on. The blood, if possible, should be examined as soon as it is drawn from the vein. It is placed in a bottle stopped with a cork, supporting a curved tube, which latter is heated by a spirit lamp. Into the end of the tube is introduced a bit of paper covered with paste, to support some iodide of potassium. The bottle is now placed in boiling water. The chloroform is volatilized, and is decomposed while traversing the heated part of the tube. The iodide of potassium, again, is decomposed by the free chlorine; and the iodine, in its turn, being set free, acts on the starch of the paste, and gives the characteristic blue colour. M. Rogsky, the author of this method, assures us that it will detect an hundred-thousandth part of chloroform in the blood. The intensity of the blue colour, arising from the action of the free iodine on the starch, will give some measure of the quantity of chloroform.

Chloroform in Veterinary Surgery.—On Monday week the operation of "firing" was performed on a large wagon-horse, while under the influence of chloroform, by Mr. Stanley. After inhaling chloroform for three minutes, the horse was insensible to pain; and Mr. Stanley commenced the operation by burning the leg with a red-hot iron to a considerable depth, in lines, from the knee to the hoof, and crossing them diagonally, fresh irons being repeatedly brought from the furnace. The operation lasted nearly twenty minutes; during the whole of this time the horse never moved his limb or evinced the slightest pain, but seemed enjoying a quiet slumber; shortly afterwards the animal ate and drank with his accustomed appetite, and walked home to his stable, totally unconscious of the severe operation he had undergone.—*Banbury Guardian.*

TYPHUS FEVER, TYPHOID FEVER, RELAPSING FEVER, AND FEBRICULA,

THE DISEASES COMMONLY CONFOUNDED UNDER THE TERM CONTINUED FEVER.

ILLUSTRATED BY CASES COLLECTED AT THE BED-SIDE.

By W. JENNER, M.D., Lond., Professor of Pathological Anatomy, University College; Assistant Physician to University College Hospital, &c.

(Continued from page 420.)

The first of these papers contained cases which I stated might be regarded as models of typhus fever; the second consisted of a general description of the symptoms and anatomico-pathological appearances of uncomplicated typhus fever. I propose in this and the next paper to enter into

AN EXAMINATION OF THE CONDITION, SYMPTOMS, AND COMPLICATIONS ON THE VARIATIONS IN WHICH THE DIFFERENCES OBSERVED IN INDIVIDUAL CASES OF TYPHUS FEVER DEPEND.

Age—Its influence on the Course and Symptoms.—The model cases 1, 2, 3, 4, of typhus fever narrated in the first of these papers, were aged respectively 70, 49, 26, and 6 years (a), and I shall have repeatedly to detail or to refer to the cases of individuals, whose ages respectively varied between 4 and 80 years. So far as personal observation enables me to speak, without actual numbers, I cannot say that either youth or age, as such, are predisposing causes of typhus fever.

But there are certain modifications in the disease dependent apparently on age, which it will be well, in this place, to point out.

The mortality of typhus fever is much greater among individuals at an advanced period of life than before forty. It is rarely fatal till after puberty. The only cases under puberty that I have examined after death, are detailed in this paper. (Cases 5, 8.) Both, it will be observed, proved fatal after the termination of the fever, from severe local complication set up during the progress of the original disease, *i. e.*, the typhus fever.

Case 5.—Well marked mulberry rash—severe febrile symptoms—sloughing of cornea—death either on or about the twenty-second day of disease—*twenty-six hours after death* pus in right pleura—consolidation and circumscribed gangrene of right lung—no trace of intestinal or mesenteric lesion.

William L., aged 8 years, an extremely dark-complexioned child, almost a mulatto—judging from his appearance, he had some negro blood in his veins—was admitted into the London Fever Hospital under the care of Dr. Tweedie, July 19, 1847, the fourth day of disease. On his admission the skin was free from rash. I saw him twice only, and made no note of the case during life, excepting so far as related to the eruption.

The mulberry rash, which, by the termination of the first week of the disease was well-marked, and at the end of the second week scarcely rendered paler by pressure, was by the nineteenth day very pale. From the notes of a friend I am able to state that the febrile symptoms were very severe, even before it is probable that the chest affection supervened. A few days before death, an aperture was formed in the inferior half of either cornea, about two lines in length and a line in breadth; each aperture resulted from the separation of a slough. The irides protruded through the openings. The following appearances were observed on examination of the body of William L., twenty-six hours after death.—Great emaciation.

The left pleura contained a little serosity. The left lung was free from adhesions. The lung itself, pale and crepitant anteriorly, was of a deep purple colour posteriorly. Here and there, from the posterior part of the inferior lobe, small portions of pulmonary tissue could be cut, which sank in water, contained no air, and broke down more readily than natural under pressure. This lobe contained about its centre two or three small masses of tubercle just commencing to soften.

The right pleura contained about 3 oz. of fluid resembling pus, of highly offensive odour.

The right lung was closely collapsed and corrugated externally, with the exceptions to be mentioned. The pulmonary pleura was opaque and dull white. From the centre of the closely collapsed superior lobe projected a mass about the size of half a pigeon's egg, firm and smooth; an equal quantity of the mass was buried in the substance of the lung. Its smoothness contrasted remarkably with the corrugated appearance of the lobe generally. On dividing this mass, its centre was found occupied by black semifluid matter of highly offensive odour. Stretching through the semifluid matter were delicate bands of some consistence. This absolutely gangrenous portion was about 1 in. in diameter; and was distinctly bounded by a border of soft white pulpy matter, rather less than a line in thickness. The pulmonary substance external to this white line was for some extent in every direction—soft dark purplish red, contained no air, and had a smooth and uniform section. The consolidated tissue extended outwards to the pleura.

Projecting from the inferior lobe was a prominence resembling external that observed in the superior lobe; but, on cutting into it some highly offensive gas escaped, and its anterior wall collapsed. In addition to the gas, this cavity contained some semifluid black matter and gangrenous shreds; the whole bounded by a white line similar to that described as bounding the gangrenous mass in the upper lobe. The external wall of the cavity was formed by little more than the pleura. On the free surface of the latter, corresponding with the centre of the cavity, was a black spot about the size of a split pea, with well-defined outline. There was no appearance of any attempt at the separation of this black spot from the surrounding pleura. In the vicinity of the last-described gangrenous mass were two smaller masses resembling it in appearance.

The heart, liver, spleen, pancreas, and kidneys presented no deviation from their normal state.

The *stomach, small and large intestines* were healthy throughout; the color, consistence, and thickness of the mucous membrane were normal; there was no disease of Peyer's patches; the solitary glands of the large intestines were distinct, but not diseased.

The mesenteric glands were rather large, but pale and firm.

The other organs were not examined.

This case offers a well-marked example of circumscribed gangrene of the lung. There were, it will be observed, several distinct gangrenous centres. Was this the result of the pneumonia, to which the gangrene was probably secondary, having been disseminated or lobular at its outset, and only becoming generalised or lobar by the junction of the circumferences of the several centres of inflammation? The condition of the opposite lung appears to lend a colouring of probability to this view of the case. At any rate, in conjunction with case 8, it illustrates the tendency of inflammatory action set up in the course of typhus fever, to assume a low type. The sloughing of the cornea of both eyes is of interest. If any inflammatory action of the conjunctivæ preceded it I am unable positively to say. So far as memory serves me there was little or none. Pressure, the ordinary determining cause of sloughing in typhus fever, was here out of the question, from the situation of the sloughs.

With reference to the symptoms of typhus fever, this case illustrates the fact, that the eruption appears on about the same day of the disease, and continues about as long in children as in adults; that it may be very abundant in children, and well marked in those of dark skin.

But the points on which I wish to rivet the reader's attention are, 1st, that continued fever occurred in a child not more than eight years of age; 2ndly, that the fever was accompanied by abundant mulberry rash; 3rdly, that the child died on the 22nd day of disease, within a few days after the termination of the fever, *i. e.*, if the nearly total disappearance of the rash, not from sudden retrocession, but from gradual fading, be considered (as I am inclined to consider it, from an examination of very numerous uncomplicated fatal and non-fatal cases) as a mark of the termination of the fever; and yet, that in this youthful subject, affected with severe fever, which ran its full course, no trace of intestinal lesion was discovered. The gangrene of the lung terminated the life of the boy too soon after the fever for any such lesion to have disappeared, had it ever existed.

In children the rash of typhus fever is often absent. When several cases of typhus fever occur in one house, if the mulberry rash is absent from

(a) Children under six years of age are not received into the London Fever Hospital.

any members of that family, in a large majority of cases, it is the children who are free from eruption. The following observations appear to me to prove the above assertion, so far as induction from a limited number of carefully observed facts can prove it.

I have notes of 152 cases, in which more than one member of the same family were seen by myself. There was no eruption in 16 of the 152 cases. Thirteen of these sixteen were individuals whose ages varied between 4 and 15 years inclusive; the other 3 of the 16 cases were between 16 and 22 years of age. 55 of the 152 cases were less than 15 years of age; 76, *i. e.*, just half, were more than 22 years of age; 21 of the 152 cases being between the ages of 16 and 22 inclusive. Thus the rash was *present* in every individual more than 22 years of age. It was *absent* in 3, or one-seventh of the individuals whose ages varied between 16 and 22 years, while it was also *absent* in 13, or one fourth of those 15 years of age and under. I ought to remark, that of the 13 individuals last referred to, there was in reality only one whose age exceeded 13 years. Let me express more clearly this very important fact, one, it seems to me, unequivocally proved.

Suppose 100 individuals of all ages to have typhus fever, we may expect the rash to be absent

From one-fourth, or 25 of those under puberty.
From one-seventh, or 14 of those under manhood.
From none above 22 years of age.

I would here just recall to the reader's remembrance, how frequent is sore throat without scarlet eruption in adults, after exposure to the poison of scarlet fever—an analogous fact in an analogous disease.

The cases of typhus fever without rash, are, so far as my observations extend, invariably mild, never fatal, but now and then local complications arise in the progress of the fever, so mild and harmless *in itself*, by which the patient is cut off. Cases 5 and 8 are examples of such fatal complications. Case 5 also illustrated the fact, as I before remarked, that even in young children the rash may be intense in hue, and very abundant. Cases 6 and 7 will illustrate the phenomena of the disease when the rash is absent.

Case 6.—After exposure to the contagion of typhus fever, there ensued, in a child, aged 10: frontal headache——delirium—diminished strength—pale brown dry tongue—absence of abnormal abdominal and chest signs—quick pulse. Convalescence on the 12th day.

Henry B., aged 10 years, was admitted into the London Fever Hospital under the care of Dr. Tweedie, Sept. 19, 1849. A thin, rather delicate looking child, whose previous health, however, had been very good

The following notes were made, when he first came under observation on the

6th day of disease. Slept well; mind unaffected; headache little, if any; expression natural; no flush of face. His strength is slightly impaired; but, he can leave his bed unassisted with facility. Tongue moist, slightly furred; bowels confined till after a dose of castor-oil, which acted three times; a little appetite; no gurgling; no tenderness, and no abnormal fulness nor resonance of the abdomen; pulse 100; no cough; no abnormal chest signs; skin warm and dry; no eruption; that night he got little sleep, was very restless; on the 7th day the restlessness continued, and he complained of frontal headache; the tongue was dry, smooth, and covered with a yellowish brown fur; he passed two stools; he had little sleep at night, was restless and slightly delirious; the mind continued to wander at intervals during the following day. His pulse never exceeded 108, and his bowels continued regular throughout; he was convalescent on about the 12th day.

Several members of this child's family were admitted with well-marked typhus fever. His sister, aged 6½ years, was received into the Hospital at the same time; her illness had commenced on the same day, and she was also convalescent on from the 10th to the 12th day of disease. This little child had marked, but scanty, mulberry rash. The spots were present on the 6th day, at which time the notes of her case were first taken; they had nearly disappeared on the 10th day, when the last notes respecting them were made.

The treatment in these cases was simply expectant. Castor oil was administered when the bowels were confined; the hair removed and cold applied to the scalp, when the pain in the head became severe, or delirium supervened. A large, well-ventilated apartment, fresh air, a cool, but not cold, atmosphere, quiet, abstinence from solids, and a free supply of cold water, milk and water, and weak broth, these are the remedies on which, in a large majority of cases of typhus fever, the judicious practitioner relies for the safety of his patient.

In no disease is the advantage of refraining from meddling more clearly displayed than in typhus fever. In no disease is the prompt use of powerful remedies more clearly indicated than in typhus fever. It is in determining when to act, and when to do nothing, that the skill of the physician as a curer of disease, or, rather, with reference to fever, as an averter of death, is shown. Interfere, bleed or stimulate, when nothing should be done, and the patient, but for you safe, is lost. Refrain from depletion or withhold wine, when the one or the other is required, and the patient sinks into that grave from which judicious treatment might have saved him.

Case 7.—After exposure to contagion from persons labouring under typhus fever, with mulberry rash, there ensued, in a child, aged 7: frontal headache—disturbed sleep—heaviness of expression—debility—confined bowels—loss of appetite—quick pulse—hot skin—no rash—convalescence on the 13th or 14th day.

Sarah M., aged 7, was admitted into the London Fever Hospital November 2nd, 1848, under the care of Dr. A. Tweedie. A delicate looking, fair child, who had been ill three days only before she came under observation.

The following were the symptoms at that time:—She had slept several hours the preceding night, but moaned much in her sleep; she complained of much headache, which she described as confined to the forehead; was quite sensible, and remembered the date of her entrance into the Hospital; there was some heaviness of expression; the conjunctivæ were pale, the pupils natural, but she shunned the light; there was no flush of the face. She appeared very weak, but turned in bed with facility; the tongue was moist, slightly furred white; there was much thirst, no appetite, and no stool the preceding 24 hours; she swallowed without any difficulty; the abdomen was somewhat full and resonant, but not tender; she complained of a little pain in the belly; the pulse was 108, weak; there was trifling cough, but no abnormal chest signs; the skin was hot and dry; there were no spots.

There was little change in the symptoms during the progress of the disease,—excepting that the skin became moist, till the 13th or 14th day, when her appetite returned and she was noted to be convalescent.

In this case, too, as in all such cases it ought to be, the treatment was medicinally expectant. The hygienic conditions necessary for the safety of the, in itself, mild case of typhus fever being rigorously observed, *i. e.*, the child was placed in a large, uncrowded apartment, plenty of fresh air was admitted, the temperature kept at about temperate, her linen frequently changed, and solid food withheld, while her thirst was slaked with as much water as she chose to drink.

The whole family, of which No. 6 was one, were, with the exception of the mother, who had "spotted" typhus five or six years before, and a child aged 4, admitted into the London Fever Hospital between Nov. 1 and Dec. 20. The ages of these parties were respectively 14, 19, 20, 21, 22, 29, 60; in all seven the mulberry rash was well marked. The youngest child I visited at home, and found suffering from symptoms similar to those under which her sister laboured when the foregoing notes of her case were taken. She, too, had no spots; or if she had, they were too faintly marked to be seen in the dark room in which these people slept. Like her sister, she had a very mild attack.

Case 8.—After exposure to the contagion of typhus fever, there ensued, in a child aged 10——Faintly marked, scanty mulberry rash—delirium—debility—moist and white tongue—confined bowels—quick pulse—rapid respiration—dulness of left lung, commencing inferiorly—cavernous breathing—gurgling—pectoriloquy, first at inferior angle of left scapula—fetid sputa—hæmoptysis—death on about the fourty-fourth day of illness. *Twenty-nine hours after death.*—Tubercles in both lungs—consolidation of intervening tissue of left lung—enormous cavity in left lung—tubercles beneath intestinal mucous membrane and in mesenteric glands—tubercles in the spleen—opacity and increased vascularity of pericardium.

Martha A., aged 10, was admitted into the London Fever Hospital Oct. 3, 1848; a dark-complexioned, delicate girl, rather thin. Her mother, aged 50, brother, aged 16, and sister-in-law, aged 29, were admitted between Oct. 3 and Nov. 4 with typhus fever. All had well-marked mulberry rash.

As nearly as could be ascertained, she had been ill nearly a fortnight when first seen by me, Oct. 4. She had kept her bed since the 25th of September; *i. e.*, I saw her on the 10th day after she took to bed; at that time, *i. e.*, about the 14th day of disease, the following particulars were noted:—

She had passed a very restless night, and had but little sleep. She had left her bed several times while delirious. At the time of the visit she seemed quite sensible, said she had no headache, but complained of vertigo in the erect position. There was slight heaviness of expression; the complexion was muddy; the cheeks covered with a dusky flush; the conjunctivæ were pale. With the exception of a disagreeable taste the special senses were in their normal state. Although, while delirious, she left her bed unassisted, she was, when I saw her, quite unable to leave it.

The tongue was moist and white; there was considerable thirst, but no appetite; the bowels were confined; there was no tenderness, pain, abnormal fulness, resonance, nor gurgling of the abdomen. The pulse was 100, the respirations 36; the nostrils dilated largely during inspiration; there was trifling hacking cough. She complains of a sharp pain, increased by deep inspiration under the left mamma, which "took her breath away." There was a little sonorous, and much mucous râle over the anterior surface of the left side of the chest; posteriorly below the angle of the scapula there was abundant fine crepitation and some friction; at this latter part, also, there was slight want of resonance on percussion. The skin was hot and dry, and stated, in my notes, to be free from spots; but on the following day I wrote thus:—"On the abdomen and back there are seen, on careful inspection, a few irregular dusky pink spots, which fade on pressure. As these spots are very pale, her skin very dark, and there are numerous flea-bites over the same parts, they might have been overlooked yesterday." On the same day, *i. e.*, the second of observation, the 15th of illness, the cough had increased in severity; it retained its short, hacking character. There was now positive dulness from the angle of the left scapula downwards, and the breathing was tubular in the same situation; from the angle to the spine of the scapula there was abundant fine crepitation. On the 16th day the pulse was 96; the respiration 30; the cough continued, and was accompanied, for the first time, by the expectoration of some purulent fluid, coloured green, from the admixture of vomited matter; the quantity, in consequence of this admixture, could not be ascertained; the mixed fluid was highly offensive; the dulness had reached the spine of the scapula. About the angle of that bone there was abundant moist crepitation, so large as to amount almost to gurgling. At the same spot there was cavernous breathing and pectoriloquy; above there was fine crepitation. Anteriorly, on the same side, there was dulness and fine crepitation as high as the inferior border of the third rib; there was respiratory fremitus and friction sound over the same extent. She expectorated about 3 oz. of nearly homogeneous offensive purulent fluid (examined microscopically) on the 18th day. On the 22nd day the following note was made:—"The sputa, which have continued purulent and highly offensive, were this morning streaked with blood; about half an ounce of rather dark blood has just, 1 p.m., run from the mouth; no cough preceded or accompanied this discharge. On the 28th day there was dulness from the extreme base of the left lung to the spine of the scapula posteriorly, and to the lower border of the second rib anteriorly. There was no enlargement of that side of the chest, and the inter-costal spaces were well marked. The vocal fremitus was greater on the left than on the right side. From near the base posteriorly to near the middle of the scapula, there was gurgling, cavernous breathing, and whispering pectoriloquy; there was large mucous râle as high as the spine of the scapula; anteriorly and laterally there was friction and submucous râle as high as the lower

border of the second rib. By the 23rd day the dulness was complete over the whole posterior surface of the left side, and the gurgling and cavernous breathing had reached the spine of the scapula. There was some friction over the lower part of the *right* scapula. She had expectorated from 10 to 12 ounces of extremely fetid pus, mixed with a considerable quantity of dark frothy blood during the preceding twenty-four hours; the nurse stated that till 4 a.m. the expectorated matter was yellow: that while coughing at that hour, much dark frothy blood was suddenly ejected from the mouth. At the time of the visit the expectorated matter was muco-purulent, stained with blood. On the following day she expectorated from 8 to 12 ounces of purulent fluid, containing but little blood. After this the sputa continued very abundant, but became thin, watery, and of a pale dirty yellowish colour, with a little thick purulent sediment.

The pulse, 96 till the 19th day, then rose to 108, and on the 27th was 120; at this latter date the respirations were 52 in the minute. Delirium continued at intervals from her entrance till her death. She was the whole time extremely restless, and often fretful, so that often it was impossible to examine her chest. Towards the last she suffered much from night sweats and hectic flushes. The tongue became covered with a brown fur posteriorly about the 19th day. The expression of, as well as the actual prostration at the same time, increased considerably. The bowels, which acted regularly till the 36th day, then became much relaxed; at the same time she began to complain severely of griping pain in the abdomen. These symptoms continued till her death, on about the 44th day of disease. On the 38th day the belly was full and resonant, and continued so till the afternoon preceding her death, when the last note was made.

She died at half-past seven a.m., Nov. 2nd, *i.e.*, 44th day of disease.

The body of M. A was examined twenty-nine hours after death. Cadaveric rigidity was tolerably well marked. The ends of the fingers were slightly enlarged; the nails curved. There was slight discoloration of the posterior surface of the trunk. The abdomen was slightly convex; the emaciation extreme.

Head.—A considerable depression of the internal table of the frontal bone was found, and, on inquiry from the mother, was traced to an accident some six or seven months before the death of the child. (See last Vol. of the "Transactions of the Pathological Society of London.") The membranes, excepting at the spots corresponding to the injury, and the substance of encephalon were healthy in color, consistence, &c.

The *pericardium* contained about 1 oz. of turbid yellow serosity, in which floated a few shreds of lymph. The serous membrane itself was dull, white, and opaque, and there was abnormal vascularity of the parietal pericardium corresponding to the left pleura. There was no lymph adherent to the pericardium proper or parietal.

The *heart*, both substance and valves, was healthy.

The *larynx* and *trachea* were normal in appearance.

The *right pleura* contained about 2 oz. of yellowish serosity.

The *right lung* collapsed but slightly. There was a little recent lymph over the posterior part of the inferior lobe. The posterior surface of the lung was mottled with deep purple patches, here and there separated from each other by well-marked, opaque, white, interlobular septa. In the substance of the apex and anterior part of the superior and middle lobe were felt numerous irregularly nodulated, solid masses. On section these latter were found to be caused by collections of semi transparent grey granulations, and opaque yellow tubercles. Scattered between these masses were numerous solitary, minute, grey, semi-transparent granulations; the tissue around the tubercles was crepitant and apparently healthy. When the posterior part of the lung was divided, the pulmonary tissue corresponding to the purple patches described as seen externally, was non-crepitant and saturated with bloody serosity; this condition did not extend for more than from a third to half an inch into the pulmonary tissue.

The *left lung* was very firmly adherent to the pleura posteriorly, and as low as the upper border of the third rib; anteriorly from that point downwards, the anterior part of the lung was separated from the costal pleura by a collection of highly offensive dirty brown fluid, circumscribed by lymph. Opening into this cavity were several small apertures communicating through the under surface of the upper lobe, with an immense cavity reaching from near the base to near the apex of this lung, extending through the division between the two lobes. The posterior wall of this cavity was extremely thin, a mere film, about two-thirds downwards from the apex. The cavity contained a fluid resembling that in the pleura, but somewhat more purulent. The walls of the cavity were extremely ragged; large masses of sloughy matter hanging loosely from them. The pulmonary tissue yet undestroyed was stuffed full of tubercles, and numerous opaque yellow tubercles of cheesy consistence studded the walls of the cavity.

The *bronchial glands* were somewhat enlarged, and contained much dull yellow tubercular matter.

The *liver*, *pancreas*, and *kidneys* were healthy in appearance.

The *spleen* was studded with tubercles.

The *mesenteric glands* were enlarged, especially in that part corresponding to the middle of the small intestines; they varied in size from a pea to a small bean, and, on section, were found to be studded with small, opaque, yellow tubercles.

The *pharynx*, *œsophagus*, *stomach*, and *duodenum* were normal in all respects.

Beneath the mucous membrane, covering one of Peyer's patches, about eighteen inches from the commencement of the *jejunum*, were numerous distinct, firm, slightly elevated, opaque, yellowish spots, the next two or three patches descending the gut were similarly affected; then came six or seven perfectly healthy patches, and then one slightly diseased. The remainder, to the ileo cæcal valve, were normal in appearance. The whole mucous membrane of the *jejunum* and *ileum* was pale and natural in color and consistence.

The *large intestines* appeared healthy.

The urinary bladder, uterus, and ovaries were not examined.

A few of the mesenteric glands were studded with small, opaque, yellow tubercles.

The facts in this case especially worthy of attention are—

1st. Those respecting the fever. The patient was of that age when the intestinal affection is common, yet an examination after death showed that she had no such lesion (a). The illness was prolonged by local complications till the 44th day, although the fever, properly so called, terminated on about the 14th day. It is of importance, in all cases, to fix the date of the termination of the fever, for no greater error can be committed than to confound the length of the fever with the duration of the illness—to use the two expressions as synonymous terms. The intestinal lesion, diagnostic of typhus fever, was absent, although the eruption was very scanty and imperfectly marked; thus, in conjunction with other cases detailed by myself in these papers, rendering untenable the opinion first advanced in a most able article on "Continued Fever," in the 12th Volume of the *British and Foreign Review*, and subsequently adopted by Dr. Watson, that the skin eruption and the intestinal lesion are "supplementary of each other."

2nd. Those respecting the chest affection.—I can only just allude to a few of the many points of interest this case offers for consideration.

What was the order of sequence of incidents in the case.

1st. Tubercles.—The child was delicate-looking and thin, and had been for some time before her present illness suffering from cough. It is true, the ordinary signs of the presence of tubercles in the adult were not detected in the lungs on her admission; but then the elasticity of the thoracic parietes of a child, the pretty equal amount of the tubercles probably existing in the two lungs, precluding comparison, as well as their diffusion at considerable intervals from base to apex, in minute masses, might have rendered their detection impossible, (b) and certainly would have rendered it highly improbable, in a case of fever, when the attention was only secondarily directed to the chest.

(a) When treating of typhoid fever I shall refer to this case, as illustrating the difference in the appearance of tubercular and typhus deposit in the agminated glands—a difference which, in the majority of cases, forbids their being confounded by a tolerably experienced observer.

(b) "Miliary tubercles and grey granulations are made manifest by roughness of the respiratory murmur, or by prolonged expiration with clearness on percussion."—Rilliet et Barther. "Maladies des Enfants," Vol. iii. 247.

2nd. Typhus Fever.

3rd. Pleuro-pneumonia.—This was probably induced by the exposure which the child experienced in coming to the Hospital; the inflammation commenced in the situation usually occupied by lobar pneumonia of the *left* lung in children, *i.e.*, at the base.

4th. The rapid deposition of fresh tubercular matter.—This was *proved* by the large amount found in the portions of pulmonary texture, undestroyed at the time of death—an amount which must, independent of any inflammatory pneumonic consolidation, have caused absolute dulness of the left side of the thorax; and certainly no marked, even comparative, dulness existed on the child's admission.

5th. The formation of a cavity in the inferior lobe of the left lung—due, probably, to the softening down of tubercular matter, as well as to the formation of pus, and gangrene of the pulmonary tissue; in fact, a tubercular gangrenous abscess, and then the sudden opening of this abscess into a bronchial tube.

6th. The rapid extension of the cavity by a kind of phagedenic solution of its parietes.

7th. The formation of a communication between the cavity in the lung and the pleural cavity.

8th. The extension of the inflammatory action from the left pleura to the pericardium; next to rheumatism and kidney disease, the most frequent cause of pericarditis.

The rapid formation and extension of the cavity is matter of extreme interest. The physical signs were so well marked, that the exact date of the first formation of the cavity can be unequivocally fixed. The pneumonia, which was lobar, had produced but imperfect consolidation on the 11th day of disease; perfect consolidation on the 15th day, as shown by complete dulness and bronchial breathing; and on the 16th day there was indubitable evidence of the existence of a cavity communicating with a bronchial tube in the inferior lobe of the left lung. In twenty days from the commencement of the pneumonia this cavity had destroyed the greater part of the lung reaching from base to apex of the organ. The hæmorrhage was doubtless owing to the rapid extension of the cavity. The destruction of tissue was too rapid to allow of closure of the vessels. Hæmorrhage is much more common from gangrenous than from tubercular cavities.

[To be continued.]

REVIEWS

A Practical Treatise on Inflammation of the Uterus, &c. By JAMES HENRY BENNET, M.D., Physician Accoucheur to the Western General Dispensary, formerly House Physician to the Hospitals—St. Louis, La Pitié, and La Salpetrière, Paris. London: Churchill. Pp. 527.

Cadmus, it is reported, invented letters; but who discovered the art of book-making remains to this day a masonic mystery. It was probably coeval with the art of conjuring; at any rate both are intended to impose on the credulity of mankind. The famous bottle trick of Houdin is a respectable wonder; but books constructed out of other men's wits, and of paragraphs tacked together like cheap garments are an abomination. Yet they have their uses and appliances to boot. They are oftentimes monster advertisements of non-existent professional skill; they are sometimes stepping-stones to medical practice—symbols of vanity—melancholy evidences of exaggerated egoism.

"'Tis pleasant, sure, to see one's name in print;
A book's a book, although there's nothing in't."

But a book may have a great deal in it; it may contain, like a dust-cart, a vast quantity of rubbish, and loose, objectionable, and offensive matter; it may be like a shop in Rag-fair—such as old Fagan might have kept; be furnished with stolen apparel, and, as old Burton has it, one would rather a man

should steal one's clothes than one's ideas; or it may be a refectory of indigestible condiments and cooked up sophisms, which may so far impose on the gullibility of a weak intellect as to "take the reason prisoner," and make our very eyes "the fools of 'tother sense." "Go," cries King Lear, in his distraction, "get thee glass eyes, and like a scurvy politician, seem to see the things thou dost not see." But, no! "Get thee a speculum," cries the philosophic accoucheur of the day; and we fancy we see Lucina herself gently withdraw the curtain of female modesty, and reveal Dr. James Henry Bennett, ex-house Physician (*par concours*) of the Hospitals Saint Louis, Notre Dame de la Pitié, and Salpetrière, seated by the bedside of one of Juno's child-bearing daughters, propounding to her, with all the dignity of a philosopher, and with something of the fascination of a magician, the propriety and the "absolute necessity" of her submitting, not only to a manual, but to an ocular examination. From the depths of a philosophic side-pocket a shining speculum appears—a Lord Rosse's telescope in miniature—and on bended knees the exploration is commenced. Astronomers have clearly shown,—for which see Somerville, Humboldt, or more recently the Physical Atlas of Petermann and Milner,—that stars exist in the infinite regions of space, whose light, albeit moving at an inconceivable rate, has not yet reached the earth; and, in like manner, our Author discovers in his vestiges of creation, traces of ulceration which, if they not yet are, *will be*. Nay, with a truly seer-like eye, he discovers that the whole pathology of the uterine system revolves upon the axis of inflammation. "Here," quoth he, "I have endeavoured to demonstrate the important fact, that inflammation is the key stone to uterine Pathology, and that, unless the phenomena which it occasions be recognised and taken into consideration, all is doubt, obscurity, and deception." (Preface vi.) The doubt we comprehend—the obscurity we perceive—the deception we believe in. How otherwise could the discovery have been so often made in the history of obstetrics? Ideas in two individuals may be mesmerically synchronous; but, how any two heads phrenologically different could originate and contain the self-same and identical proposition, is a psychological mystery. The notion, then, of inflammation being the *tertium quid* of uterine pathology having got into the cerebrum—perhaps the cerebellum—of Dr. James Henry Bennet, off he goes in a hard canter, like Dr. Dove on the celebrated horse Nobs, (for which, see Southey's "Doctor" and not *Bell's Life*,) to explore what he innocently believes to be a *terra incognita*—a new and untrodden field of science. "Great son of Pilumnus!" exclaims my Uncle Toby, addressing Doctor Slop, "What canst thou do? Thou hast come forth unarmed—thou hast left my tire-tête, my newly-invented forceps, my crotchet, my squirt, and all my instruments of salvation and delivery behind thee. By Heaven, they are at this moment hanging up in a green baize bag betwixt two pistols at the bed's head! Ring! Call! Send Obadiah back upon the coach-horse, and bring them with all speed." In the present day, my Uncle Toby would have added to his stores the famous speculum of Dr. James Henry Bennet,—the dioptra of the ancients.

When new instruments of this description come into fashion they resemble playthings in the hands of children. They are veritable toys. When the stethoscope was first introduced there was not a tyro in the Profession who did not carry one, like a bottle-imp, in his pocket; and young ladies and old, hysteric and dyspeptic, allowed the mystic tube to explore clavicular, scapular, axillar, epigastric, hypogastric, lumbar, and even pelvic regions. But the science of Acoustics is one thing, that of Optics another:—

> "The chariest maid is prodigal enough
> If she expose her beauty to the moon.—"

And delicacy, that womanly feeling which we believe to be inherent in every virtuous breast, suggests an instinctive objection to the indiscriminate use of the speculum, which we are rather inclined to commend than condemn. But not so Dr. James Henry Bennet. He has had a Parisian insight into these matters; he has had a large and prolific experience as an Interne among the Magdalens of the Maternité, the Notre Dame de la Pitié, the Salpetrière, and the Charité; he has held communion with the saints whose names are enrolled in the canonization of the Grand Livre of the Police—the nymphs of the pavé eulogized by Eugène Sue and Paul de Kock, and whose statistics have been so ably analyzed by Parent-Duchatelet; he may have "assisted" at the balls where the *soi-disante* "Reine Pomarée" was the presiding deity, and he has come, most incontinently, and, as we believe, most erroneously, to the conclusion, that our fair countrywomen will always and unhesitatingly submit to this indecent mode of investigation.

> "I have often been told," he observes, "that females in this country will not submit to treatment when afflicted with uterine disease. I can only say that I have not found this to be the case in my own practice. I have met with many objections, but never with a decided refusal, when I have stated that an examination was imperatively necessary." (Pref xiii.)

We would feign ask, does Dr. H. Bennet limit his speculum practice to cases where the symptoms are obscure, and diagnosis difficult? or does he make a free and easy application of the instrument in cases where it might be dispensed with? We lately heard of a West end speculum Doctor, who examined one morning a mother, her eight daughters, and her *cook!* pronounced them all to labour under inflammation; and, accordingly, cauterised the whole family *secundem artem*. And a story is now rife and running of an unfortunate old lady, who, by mistake going to a wrong house, fell into the hands of a physician, who, *heigh-presto*, introduced his everlasting speculum and cauterised her os uteri for a slight bronchitis,—probably as a counter irritant; and well he succeeded, for the unfortunate patient was obliged to use a water cushion for the next week.

But to the book itself. We have here a goodly volume of 530 pages; and without offending publisher, printer, paper maker, or printer's devil, (whom we reverence,) it is wonderful to think how many pages can be stitched together without a single ray of original thought, or retrospective experience, to throw a gleam of light upon a solitary sentence.

The work is divided into fifteen lengthy chapters, and an Appendix. After some preliminary remarks, partly of an historic character, and referring to the state of medicine in the Middle Ages, we are introduced, in Chap. II., to some A B C details, as to the anatomy of the uterus, with an engraving of it and the lateral ligaments, reduced from Quain's plates, and of course, very entertaining to the advanced reader. At Chap. III. the Author beginning his task of book-making, favours us with a description of inflammation of the uterus (metritis) in the non puerperal state. The sketch, indeed, is avowedly a fancy one; and chiefly remarkable for the following strange description of pain over the affected organ:—"The most prominent local symptom is severe pain, situated deeply in the hypogastric region, above and behind the pubis, *irradiating* into the ovarian region and down the thighs. The cutaneous surface of the inferior abdominal region, *from the umbilicus to the groin*, is sensitive to the touch; but slight pressure on the abdominal parietes does not very much exacerbate the deep-seated pain. On examining digitally," &c. *Ohe! jam satis.*

"Chronic metritis," in the unmarried portion of the female population, next comes under notice—a disease, we need scarcely say, quite as rare as its predecessor. Dr. Bennet, however, thinks otherwise, and that because, on entering a room of a patient, he can tell,—"Dogs have such intelligent noses," as Lord Byron says—"by the physiognomy alone, if menstruation is impending or has commenced." Nay, he is quite ready to tilt a lance with other writers on this and all similar subjects. Though Boivin, Duges, Rigby, Waller, Ashwell, and a thousand and one other writers on obstetrics, may all combine to differ with him, he preserves his own opinion unshaken. Dr. Ashwell, in his immense field of observation, for instance, finds the average of ulceration of the cervix, just two per cent., while our marvellous Author (p. 20) startles us with the appalling fact, that out of 300 similar cases that came under his care, not less than 222 were thus affected—just 74 per cent.!

Chronic metritis occurs, so says Dr. Bennet, in 9 cases out of 10, in the *posterior wall* of the uterus; it is difficult of cure, and very liable to be confounded with cancer,—all, no doubt, striking novelties. A careful digital examination is of course the one thing needful, and the speculum the grand catholicon.

Heigho! the wind and the rain!—The subject of uterine catarrh follows, and an immensity of hair-splitting, on the *diagnosis* of internal metritis. Continental writers have written a great deal on the matter; but they are "evidently quite ignorant," we are assured—oh, unkindest cut of all!—"of the normal existence of the internal sphincter;" they cure with their injections, sundry uterine affections, it is true, but they do not, it seems, know *how* they do it, without exposing every one of their very fortunate patients to a specular examination.

Next comes "Inflammation of the Uterine Appendages;" and twenty-four mortiferously stupid pages are taken up with the consideration of this form of pelvic inflammation, with an exposition of the fact, that it is usually—except of course by Dr. Bennet—nay, always and ever, confounded with iliac abscess. Directions for diagnosis are pointed out with a rare idea of the very neglected education of the reader, and the ignorance of Gooch, Clarke, Churchill, Ashwell, and others also, as usual, very commendably set forth.

Still Dr. Bennet is a prophet, for at page 85, the more ignorant portion of the Profession are informed, that "the peritoneum in the female, after covering the posterior surface of the bladder, is reflected on the uterus, covers the anterior surface of the body of the uterus, its posterior surface, and is then again reflected on the rectum. As it passes from the anterior to the posterior wall it forms two wide folds,"—yes, two wide folds—"and these contain the Fallopian tubes, the ovaries, and the round ligaments;" moreover, that these two folds are separated from each other by cellular tissues liable to inflammation, with one or two other equally notable revelations. What a wonderful man that Dr. Bennet, to throw such light on so difficult a point!

Much prosing follows on the more marked puerperal form of the disease, where we have, it is true,

little room for discoveries, the writer himself being scarcely able to separate it from iliac abscess, properly so called.

After so much verbiage, we reach page 86, where the real matter of the book would seem to begin — *Inflammation and Ulceration of the Uterus*, and this we find under the five following forms:—In the Virgin—In the Pregnant Female—During and after Abortion and Parturition—In Advanced Life—And as as a Concomitant of Polypi and Fibrous Tumours. These are all treated *seriatim*.

In the first division of the subject, the character of the cervix uteri in the virgin is pointed out with much minuteness. Though previous to menstruation the uterus lies dormant, after that period a different state of things obtains. Owing to an extreme sensitiveness of some females at this halcyon epoch, ulceration and inflammation, Dr. Bennet assures us, often follows, in a *few days* or weeks, this change of condition; and when such is the case, they mostly remain sterile. This, we take it, for obvious reasons, is a point difficult to establish one way or another. When conception takes place, we quite agree with our oracular friend, other causes of inflammation come into action, and a new life, very often a troublesome one, dawns on this very essential part of the female œconomy.

Ulceration, of course, follows inflammation, and is treated with a world of minuteness. "The secretion from an ulcerated surface," we are informed, "is purulent." And yet, in practice, need we say, every conceivable admixture of mucus and pus is met with, together with the white creamy secretion, the result of congestion. The glairy mucus, so like the white of egg, that every one has seen in the every-day speculum examinations of our Hospitals, and ordinarily ascribed to a cachectic condition of the uterine organs, Dr. Bennet is more than usually mystical about, and at once puts down to inflammation; a patulous condition of the os uteri, with this peculiar secretion, in his opinion, being pathognomic of inflammation of the *cavity* of the cervix.

Extension of Inflammation to the "vagina and vulva," attended with intolerable itching to the "rectum and bladder," &c., next follow—for what earthly purpose besides book-making, we are at a loss to divine. Sterility, we are again assured, as something very original, arises also from a similar cause; also uterine inertia, or absence of all sexual appetite, and Dyspepsia, with its Pandora's box of all shapeless evils. Dyspepsia, of course, is the result of the re-action of an ulcer of the womb on the par vagum, and to be treated accordingly. Nay, to such an extent does our Author carry his position, that in young ladies who disorder their stomachs with jam tarts and such peccable eatables, even though they may not confess the impeachment—so continually does Dr. Bennet modulate on one string—"that the very existence of severe disorder of the digestive functions in a young female, always induces him to question narrowly the state of the uterine functions." A speculum examination, of course, very properly supersedes the old black draught and blue pill.

Our Author also finds the liver enormously enlarged from disease of the neck of the uterus; the upper portion of the colon, the several thoracic organs, the organs of the circulation:—nay, he has repeatedly seen patients debilitated "by ulcerated inflammation of the cervix attacked with pulmonary consumption."

This form of disease, our Author further enlightens the Profession, is the source of various cerebral aberrations, produces lowness of spirits, amaurosis, deafness, nightmare, and hysteria; in short, every ill to which poor feminine flesh is heir.

Now, in all this, we must, for ourselves, commit so flagrant heterodoxy as to say, that we think our Author too often puts a *post hoc* for a *propter*. We have lived through Broussaism, and the "ism" of old John Abernethy—Plessimetry, Electro-Biology, and a score of other rocket-like systems; and our recollections are not the most favourable of things that prove too much. That all our great writers on obstetrics should be so ignorant as Dr. Bennet would have us believe, is another matter to which we must beg leave to demur.

At page 159, our Author buckles on his armour for fresh encounters, and goes back to begin, if we may be permitted a Hibernianism. We have, accordingly, inflammation and ulceration of the neck of the uterus again in the virgin female, and its connexion with leucorrhœa, dysmenorrhœa, amenorrhœa, all pointed out quite to his own satisfaction; details which, in the usual Sir Oracle's mood, he tells us, he is quite aware will be read with considerable surprise, even by those practitioners who have paid the most attention to uterine diseases.

We have next some ninety or a hundred pages, chiefly occupied with cases, every word of which we have read, but in which we see nothing of novelty. At page 228 we are assured, that where hæmorrhage exists after delivery, there will be *nearly always* found some inflammatory and ulcerated lesion of the cervix; that, in cases of abortion the same state of things obtains, of which the ordinary practitioner is profoundly ignorant.

At the "critical" period of life of course our Author meets with ulceration. The atrophy of the uterine system at this epoch no doubt exerts a salutary influence; yet Dr. Bennet seems to feel some very peculiar compunction for "that large floating population of women" who have, up to this period, neglected speculum examination—"stranded on the shore of the stream of life," poor things, without ever dreaming of the fanaticism of our French friends.

Ulceration of the cervix accompanying polypi and inflammation of the vagina and vulva, form the subject of Chapters X. and XI. The latter affection, he assures us, often leads to ulceration of the cervix; not unfrequently, also, to a suspicion of syphilis. Any one, indeed, who has attentively studied among the heaps of cases of this kind in Paris, Berlin, and other continental cities, must at once recognise this affection. An ulcer, possibly as large as a franc piece, on the inside of the vulva, which nothing can heal, and which in many instances gives no uneasiness to the patient herself, is too often we think confounded with something of a more formidable character—at least in this country—not to speak of the true syphilitic sore itself.

Chapter XII. is another recapitulation of the whole matter, showing the dependence of all possible female disorders, including hysteria, abortion, prolapsus, anteversion! retroversion!! and retroflexion!!! on NEGLECT OF THE SPECULUM. We must spare the reader, however, these 40 pages, syphilitic ulceration bringing us to page 312; where, however, some practical observations as observed in the Paris hospitals, make amends for the many previous absurdities. The rarity of the true Hunterian chancre first pointed out, Dr. Bennet goes on to demonstrate that many others considered not very different, are in reality secondary sores, others merely inflammatory, requiring no specific treatment.

The succeeding part of the work treats of cancer of the uterus, that fertile source of contending opinion and discussion. We cannot see much of originality in it. Sundry wooden men are put up to be knocked down, and the reader is left in as much doubt as before. Montgomery, and Ashwell, and Clarke, are shown, as usual, to know nothing of true cancerous disease, which Dr. Bennet thinks is only to be managed in his own particular way. The concluding chapter winds up with some general directions on treatment, addressed to his more elementary friends, which however useful, we must pass over, since we are exceeding our limits and our readers' patience, and shall require an ignis fatuus from Mephistopheles, or from Dr. Bennet's own speculum, to guide us back again. The volume before us adds nothing to our theoretical or practical knowledge of uterine diseases. "Young man," said Dr. Parr, addressing a conceited Oxonian, "if you knew *nothing*, you would soon learn *something*;" and if Dr. Bennet would forego his Parisian experience, and lay his speculum aside, he would, by diligently studying the writings of his contemporaries, derive a great deal of information which might prove, in the fortuitous course of his obstetrical practice, useful both to his patients and to himself.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

November 27, 1849.

Dr. Addison, President, in the chair.

ON THE SECTION OF THE TENDO-ACHILLIS IN SOME CASES OF FRACTURE OF THE BONES OF THE LEG.

By CAMPBELL DE MORGAN, Esq., Surgeon to the Middlesex Hospital.

After referring to the operation of tenotomy, as practised not infrequently on the Continent in cases of fracture, when unusual difficulty is experienced in reducing and keeping quiescent the fractured ends of a bone, the author related the following cases illustrative of this practice, where the tibia and fibula were the seat of injury, and the tendo-achillis that of the operation. He believes they are the only instances thus treated in this country. The first case is furnished by Mr. Shaw, in whose practice it occurred:—W. S., aged 40, was admitted into the Middlesex Hospital on Feb. 12, 1847, having fallen down stairs in a state of intoxication. Both bones of the leg were broken, and the fracture of the tibia extended through both malleoli, the foot being twisted outwards. Violent spasms of the muscles frustrated all attempts to keep the fractured extremities of the bones in apposition; the slightest movement brought on this spasmodic contraction, which extended to all the muscles of the limb, so as to cause great distortion of the foot, and render the skin over the base of the tibia extremely tense. All the symptoms continuing unabated on the following day, and the suffering of the patient being considerable, Mr. Shaw determined on dividing, in the usual way, the tendo achillis, which was very tense. After this all the difficulties entirely ceased, and no further trouble was experienced in the treatment of the case. The second case occurred in the author's own practice. The patient was a female, aged sixty-six, of drunken habits, and was admitted into the Middlesex Hospital in March, 1849. She had been knocked down by a cab, and both bones of one leg were fractured a little above the ancle. The symptoms and condition of this patient were very similar to those of the last, and every mechanical and therapeutic measure which could be suggested to relieve the spasms was tried in vain. The author divided the tendo achillis on the ninth day, with instant relief to the suffering of the patient, and immediate removal of all untoward symptoms. In less than a month, the chasm left after division of the tendon, which was not very great, had disappeared; and a fortnight subsequently, she was able to walk on crutches, and the foot was free from deformity. After some general remarks on the value of the operation in the foregoing cases in re-

lieving suffering and spasm, the author proceeded to remark, that he thought so simple and harmless a proceeding as dividing the tendo achillis might be adopted with advantage in other cases of more frequent occurrence, especially as the cure would not thereby be retarded. He concluded with noticing a remark of M. Bonnet's, that he has frequently divided the tendo achillis in cases of diseased ankle-joint, where rest was imperative, and the heel was drawn up by the muscles inserted into it.

Mr. B. Phillips remarked, that the plan of proceeding proposed by Mr. de Morgan had been adopted to a certain extent in France and Germany, but he hoped it would not be carried out as fully here, in England. It was not generally necessary to divide the tendon of the rectus muscle in the case of a fractured patella, or of the triceps in that of a fractured olecranon. Still cases might occur where such an operation might be useful. It must be remembered, that, in such cases, the operation is performed on tendons, which are of the proper length at the time. All the members of the Society are aware that when the section of a tendon is practised, the cut ends separate to a certain distance—to half an inch, or more. In the cases before them, the chasm was very considerable, and such is generally the case. The result is, that a large quantity of new matter must be formed, sufficient to fill up this chasm, and the tendon is thereby lengthened. In club-foot the tendon is already too short, and it is cut to make it longer; that end is obtained by the operation. When, however, the tendon is of its due length, there is no need for the operation, and harm must follow its performance. The same thing happens in cases of rupture of the tendo achilis; it becomes too long, and the heel is never fully raised from the ground. He (Mr. Phillips) referred to the case of the late Mr. Justice Taunton, who ruptured his tendo Achillis while dancing, and was lame for life afterwards. Although it appeared that this lengthening did not occur in Mr. de Morgan's cases, such a result might be generally anticipated, and would, he feared, prove the point of difficulty in the operation.

Mr. Lonsdale, in reply to Mr. Phillips, said, there would be no reason to fear the elongation of the divided tendon. In fact, if the foot be not kept sufficiently flexed, the tendon would contract too much. The only case in which elongation might be feared would be when the muscle is palsied; in the healthy limb, if the parts be kept in contact, there would not be any reason to fear an unnatural elongation of the tendon. It was an occurrence he had never met with.

Mr. Avery, in a few words, confirmed the statement made by the last speaker.

Mr. de Morgan wished to correct an error into which Mr. Phillips had fallen, by overlooking the word "not;" the chasm between the divided ends of the tendon never was very great; it never exceeded a quarter of an inch, that space being sufficient for the reduction of the fracture, and shortly afterwards it was scarcely appreciable. He was not inclined, from the results of his experience, to anticipate that any lengthening of a tendon would follow its subcutaneous section, nor could he admit that cases in which tendons had been ruptured were at all analogous to those in which their division had been effected by surgical interposition. From what he had seen of the cases he had brought before the Society, he should not hesitate to operate in others of less severity, and certainly not, if by doing so he could save or prevent a few nights being passed in suffering from spasm. In cases of fracture of both bones of the leg near the malleolus, although the spasmodic action of the muscles might, perhaps, be checked by the application of splints, he nevertheless would feel himself justified in operating.

Mr. Charles Hawkins remarked, that as the occurrence of spasms during the first few days after a fracture greatly interfered with the well doing of the patient, he thought the operation might be usefully performed, as it might also in other cases in which fracture had not taken place. He had no fear of the elongation of the tendon, a result which he had never met with. Cases of fracture of the patella were, perhaps, in their result less creditable to a surgeon than any other accident. The patient had rarely afterwards an useful limb, owing in a great measure, as he thought, to the impossibility of keeping the ends of the bone in apposition. In one case, and in one case only, had he seen bony union occur, and in that the other patella was shortly afterwards broken, and the patient was lamed for life. He had seen a case lately in which as he thought, this operation might be advantageously performed. About a year and a half ago, a lady was driving in a country road, and being frightened at a cart which was coming, jumped out. She walked home afterwards, and then complained of her ancle. Medical assistance was obtained, but no benefit was derived. The late Mr. Key was called in, and he made a caustic issue near the joint, but without advantage. Mr. C. Hawkins was consulted about a month since; he found that the ancle was not injured, but the tendo achillis was so contracted that she could not bring her heel to the ground, and she walked consequently with a high-heeled shoe. The pain which this patient suffered was very severe, and he thought it not impossible that, in such a case, relief might be afforded by the operation under question. It might prevent the recurrence of the spasm; at all events, he believed it ought to be tried, as it was one of great simplicity.

Mr. Le Gros Clark did not agree in the recommendation to divide the ligamentum patellæ in cases of fracture of that bone; neither did he regard it as an unimportant operation, on account of its contiguity to the knee joint. He thought, that if it were performed, the tendon would elongate, and thus, what was gained in one direction, would be lost in another.

Mr. Lloyd believed, that when a tendon had been divided there was at first a chasm, but when the cure is effected, the separation of the divided ends is very slight indeed, and, very often, it cannot be ascertained where the division has been effected. He was of opinion that the proposed operation would be useful in those cases of fracture where it was difficult to keep the broken portions of bone in apposition, especially when the muscular contraction caused the riding of the upper part of the bone. He believed that, after fracture of the patella, patients generally recover with very good limbs, and are as able to walk as before the accident happened. The drawing master of Christ's Hospital fractured both patellæ; after a time, he fully recovered, and could take long walks. Younger persons recover thoroughly after such accidents. A gentleman, who was a great sportsman, and also much addicted to walking, fractured his patella, the injury not being discovered until long afterwards, his leg having been broken at the same time. When the fracture of the leg was cured, that of the patella was discovered, and then the broken ends of the bone were separated to the extent of three inches. Notwithstanding this, after the lapse of a year and a half, he was enabled to resume his shooting, and apparently walked as well as ever. Mr. Lloyd objected to any attempt being made to bring the broken pieces of bone together by force. Synovitis and other unpleasant accidents would occur, and the patient would never have a good limb. He would treat such cases by position only, and he always sent them out of hospital with a very small intervening space between the fractured portions, and with a very good limb. He had only seen one case of bony union.

Mr. Charles Hawkins had referred in his remarks to cases of fractured patella, after they had left the hospital, of which he had had the fortune to examine several. When the limb began to be used, the intervening substance began to elongate, and this ultimately greatly impaired the utility of the limb. This was the case with a country gentleman, who had met with the accident. As soon as he began to take exercise, the elongation commenced, and his limb weakened. In the only case of bony union which he had seen, the patella had been broken by a direct blow. Great inflammation followed; no apparatus was employed; and the patient ultimately fully recovered with a sound limb. He afterwards fractured the other patella, and in that case bony union did not occur; and when he used the limb the intervening space lengthened, and the limb became comparatively weak.

Mr. Bainbridge, of Tooting, spoke of two cases of fracture of the patella, in which he had successfully employed the late Mr. Earle's gun apparatus, and said that patients were able to walk about with it in a few days after the accident, as well as if nothing had happened. He also mentioned cases in which patients were able to walk about and perform their ordinary avocations, after a cure had been effected, although the broken portions of bone were widely separated.

Mr. Hodgson, of Birmingham, was of opinion that shortening of the tendon occurred after its section, instead of its elongation. After division of the tendo Achillis, he had not found it necessary to employ a complicated apparatus, which, by the pressure it exerted, caused sloughing sores, and thereby retarded the cure. Passive exercise three or four times a day would be generally sufficient, and, when it could be done, standing on the leg, and swinging it to and fro. In every case of fracture of the patella which he had examined after death, the union had been by cartilage or ligament, and not by bone. This he regarded as a wise provision of nature, as the exudation of the callus in cases of bony union must, more or less, interfere with the motions of the joint. He had seen two or three instances in which the tendon of the rectus had been ruptured; and, in all, the chasm thus formed remained for life, and was the source of great annoyance. In one of these cases the patient was a medical man, and the accident was the cause of great inconvenience to him. Every means were used to remedy it, but in vain; he remained lame for life.

Mr. Lonsdale observed, that the shorter the ligamentous union was, the better it was for the patient. He had never seen a person, in whom there was a long ligament between the fractured pieces of bone, walk well. As long as the upper part of the bone remained over the trochlea of the femur, the patient would have a comparatively useful limb. Beyond that the limb must be weakened. He had never seen bony union in transverse fracture of the patella.

Mr. Lloyd stated, that when he sent patients out of the hospital, after treatment for fractured patella, a splint was placed at the back of the joint so as to keep the limb extended for a certain time. The splint was kept there, indeed, during the whole treatment of the case. The consequence was, that that the upper part of the broken bone was not drawn away from the lower, after the person had ceased to be under his care.

Mr. Erichsen considered the operation justifiable in cases of fracture of the leg low down, when muscular spasm prevented the keeping the foot in position. In one class of injuries this operation had been performed, although it had not been alluded to by any of the speakers, namely, that of dislocation of the astragalus forwards. The difficulty, in such cases, arises from the upper surface of the os calcis being jammed against the tibia, from which it cannot be replaced, except after the section of the tendo achillis, when the foot can be drawn downwards, and the astragalus reduced. This improvement we owed to the modern school of Dublin Surgery. Cases of this dislocation have been left unreduced, because the strong spasm of the muscles of the calf could not be overcome.

Mr. Shaw mentioned a case of dislocation of the astragalus, which had been under Mr. Arnott's care in the Middlesex Hospital. The division of the tendon was effected, but the fracture could not be reduced, and the bone was ultimately excised. The patient did well.

CASE OF MONSTROSITY.

By JAMES BOWER HARRISON, M.R.C.S.E.
Formerly Surgeon to the Ardwick and Ancoats Dispensary, Manchester.
(Communicated by Dr. W. VESALIUS PETTIGREW.)

The author was called on the 10th of January, 1849, about seven o'clock in the evening, to attend a poor woman who was in labour. On making a vaginal examination, he found the membranes protruded in a pyriform tumour, but could not detect through them any part of the child. After the membranes had burst, he made a further examination,

and felt a soft tumour presenting, which resembled the bag or membranes before it had ruptured. Passing his hand around the tumour, he at length discovered a hard substance partially concealed between the tumour and the parietes of the uterus. This hard body was a distorted leg and foot. A ligature was passed round the foot; ergot of rye was given; the pains, before feeble, became stronger and, with the aid of slight traction, the foot was brought down, when a finger passed up to the top of the thigh felt a substance which resembled the body of a child having only one leg and no organs of generation; the soft mass being still felt. After some time, the whole mass, with the distorted body of the child, descended and came through the os externum. The fœtus was a monstrous growth. The soft mass was found to be a hernial protrusion of the abdominal viscera, owing to the deficiency of the abdominal parietes below the umbilicus. The navel-string had become detached. The right leg was directed transversely, and the foot curved inwards. The left leg was pushed upwards, out of its proper position, by a second tumour, the sac of a spina bifida, the left foot being curved like the other. The ossa pubis were deficient, as well as the spinous and transverse processes of the lower vertebræ, and the posterior walls of the sacrum. The genital organs were imperfect; the head, shoulders, arms, and chest, were all natural. Some little time having elapsed, the placenta was removed with the hand; the whole being accomplished by about ten, or half-past ten o'clock; the mother did well. The author regards this case as having considerable interest in an obstetrical point of view particularly as regards the presentation of a soft tumour in the manner described.

A good drawing, by Mr. Stephenson, was exhibited, which showed the distorted form of the fœtus.

MEDICAL SOCIETY OF LONDON.
Nov. 19, 1849.

F. Hird, Esq., in the Chair.

PROPOSITIONS ON CHOLERA—PARTIAL PARALYSIS—EFFECTS OF STEEL—ULCERATION OF THE APPENDIX VERMIFORMIS.

Mr. Dendy submitted the following propositions as the result of his experience during the late epidemic:—

The name should be Acholera. Because when cholera or gall-flux is established, the prognosis becomes favourable.

It is the first stage of a dynamic fever. Because this fever in varied degrees is constantly developed on the subsidence of the flux.

The predisposing causes are anxiety, low living, bad habits, crowded localities, malaria of decomposition. Because the absence of these is proved to be prophylactic.

It is epidemic, and essentially contagious. Because there was a prevalent establishment of the disease over a large space of the kingdom in a few days.

The existing cause is a poison imbibed or inhaled, influencing the ganglia, the blood, and the bowels—the symptoms enduring until the poison is destroyed or expelled. Because spasms, dycrasia of the blood, and intestinal flux are the consequence of the blood being rendered unfit for circulation and secretion.

That premonitory diarrhœa is not an essence of the disease. Because the epithelial flakes are fewer in diarrhœa, and we have periodically a severe diarrhœa, not formidable unless a malignant epidemic be prevalent.

Diarrhœa renders its subjects highly susceptible to the malignant invasion. Because as the uterus during parturition, so the mucous membrane during diarrhœa is a *weak point* in the system.

The flux would probably be a *safety-valve* to the system, as the pustule of variola, and the exanthem of rubeola, and prove salutary, if the systemic energy were sufficient. Because many of the highly malignant and speedily fatal cases occurred without this flux; and because like that of inflammation, its unfettered intensity destroys.

The result of the malady depends essentially on the resisting power of the system, *quoad* the dose of poison introduced. Because persons in various conditions, and subject to the same influence, present symptoms of varied intensity.

Prognosis must be formed chiefly from the re-establishment of the secretions. Because this indicates a renovation of the blood, and the elimination of deleterious matters from the system.

There is no specific antidote to the poison yet discovered. The adoption of one remedy (?) from isolated experience is unscientific, and its advocacy perilous. The unlimited exhibition of alcohol and opium is unsafe. Because it is so often followed by fever and narcotism.

Mr. Clarke brought before the meeting a lad, 11 years of age, labouring under paralysis of the left deltoid, and biceps of two months' duration, and occurring without any known cause. He was a coach-trimmer by trade, and only exposed to lead poison when working in coaches after they had been freshly painted. He did not present any symptoms of the poison of lead having acted on the system. The paralysis was of motion only, sensation remaining perfect. The arm was not smaller than the other; no tenderness or irritation about the spine had not sustained any local injury; sight good The case was looked upon, in some degree, as choreal, in consequence of peculiar muscular twitching in the face. Tonics, frictions, and galvanism had been tried without effect. The peculiar galvanic influence had been felt, but no benefit had followed its employment.

A Member thought that masturbation might have been the cause of this anomalous affection, but it appeared that no inquiry had been made on that head, and it was regarded as a delicate subject to question upon. Its connexion with chorea and hysteria was discussed, and led to remarks respecting the uses of the valerianate of zinc and steel tonics. Mr. Clarke said, in this case he had given the muriate of iron tincture for a month. He had commenced with ten drops three times a day and had gradually raised it to half drachm doses. He had given it, in fact, until the head became slightly affected, when he was obliged to leave it off. Not the slightest benefit followed its use.

Mr. Dendy had tried both the valerianate and the the sulphate of zinc in practice, and considered the former as the preferable medicine, but its odour was so offensive that few ladies could be induced to persist in taking it. The preparation he had used had been brought from France. It had proved very serviceable.

Mr. Shearly had used it in grain-and a half doses three times a day, in cases of chorea, in the form of pills. The patients recovered rapidly. He wished to mention that he had used a saturated tincture of capsicum, as an external counter-irritant, in cases of otitis and diseases of the eye, with great advantage.

Mr. Headland was of opinion that Mr. Clarke's case resembled in some degree those narrated by him to the Society some few weeks ago, and that it was more allied to hysteria than to any other complaint. It probably depended on masturbation, which, it is well known, prostrates the nervous system greatly, and induces maladies attended with very anomalous symptoms. When such occur in lads, he should be tempted to suspect the habit of onanism. With respect to the treatment of such cases, he had had reason to be disappointed with the effects of chalybeates, and he believed they yielded more readily to change of air and scene, and to treatment applied to the mental condition, rather than to the physical state of health. The change of air would be the more beneficial, if the sea-side were selected for residence. Mr. Headland further gave it as his opinion that preparations of steel should not be used in cases where there was red tongue; under such circumstances it not only was of no use, but might prove injurious. The cases in which a white or flaccid tongue, with great anemia, was met with, were those where chalybeate preparations would be most advantageous. The selection of a particular preparation of steel, according to the case in which it was to be used, was very important. The mere tonic effect could be obtained from several, but experience led us to prefer one preparation to another in certain cases. In cases connected with a strumous diathesis, for instance, the combination of iodine with iron—the iodide of iron—would be more serviceable than either of them separately. This salt was best given in the form of syrup, as it is not liable then to decomposition. In leuco-phlegmatic habits, in suppression of the catamenia, with a soft, moist skin, the sulphate of iron in large doses may be serviceable. The hydrochlorate of steel is not given with the same view as the sulphate, iodide, or carbonate. It has a more special action than the other preparations; when taken after a meal, in certain cases of dyspepsia in leuco-phlegmatic habits, it has a singularly beneficial influence; but it is not suited for cases of amenorrhea, nor of struma. In some cases in which iron is supposed to be of use, viz., those of neuralgia, many different preparations have been used, but none are of equal benefit with the carbonate. There is something yet unexplained in the beneficial action of preparations of steel, as evidenced by their habitual employment in cases of chlorosis and menorrhagia. Without supposing that it is not of service in these opposite conditions, he thought practitioners must exhibit it with different anticipations of its operation on the system.

Mr. Hird described the case of a little boy, whom he had been asked to see some days previously, when in a dying state. The child was subject to congenital hernia, and after catching cold, presented symptoms of strangulation, such as persistent vomiting, pain and fulness in the right inguinal region, collapse, and continuous constipation. The fulness in the right inguinal region was soon followed by tenderness, which extended over the whole abdomen; and the latter was speedily tympanitic. The canal was carefully examined, but no rupture could be detected. Mr. Hird's opinion was adverse to an operation, and the patient died the next day. The body was examined ten hours after death. On laying open the abdomen, pus escaped from between the surface of the intestine and the peritoneum lining the abdominal parietes. Extensive adhesions were discovered, with other indications of inflammation, and also a small ulceration in the appendix vermiformis. Nothing could be ascertained which could have led to the occurrence of such mischief, but it appeared that the boy had had two similar attacks previously. Mr. Hird was opposed to an operation in this case, because the child was evidently dying, and because the few operations which had been practised in similar cases had all failed.

November 26.

Henry Hancock, Esq., President.

DOUBLE COMPOUND FRACTURE OF THE TIBIA AND FIBULA.

Mr. Hunt narrated a case of compound fracture of both bones of the leg, which occurred in his practice a few years since at Herne Bay. The patient was a heavy young man, a plumber by trade, who fell from a height of fourteen feet on to a gravel walk, in consequence of the breaking of the ladder on which he was at the time. He fell on his feet, and said he heard distinctly the snap of the bones of the leg, and as he fell again, he heard another snap. On examination, both the bones of that leg were found to be broken just above the ancle, the joint being intact; the broken ends of the bones were forced through the integuments. Another compound fracture of both bones had occurred higher up the leg, the portions intermediate to the two fractures lying transversely across the limb. There was not any comminution of the bone, nor was there much hemorrhage. The application of moderate extension soon caused the displaced and projecting portions of bone to return to their place; the patient was then laid on a mattrass, on the side on which the fracture had occurred, with the leg semi-flexed, and surrounded with a napkin, but not tightly. Tepid-water dressing only was used. After a few days some swelling occurred, to relieve which the napkin was snipped; when this had subsided, there was very little pain, and the patient went on well. After ten weeks had passed away, the pieces of lint over the wounds were removed, and the compound fractures were found converted into simple ones. Bony union had taken place, and in a few weeks more the patient was able to walk about,

and employ himself in his business. There was not any subsequent deformity. The fractures were treated throughout without the application of splints. Mr. Hunt observed, that he had not brought the case forwards as exhibiting any novelty in its treatment, but as illustrative of successful treatment in the pure air of the country, and with the strong constitutions of countrymen, of a bad case, which, had it occurred in a London Hospital; would be deemed a proper one for amputation. He had himself been doubtful of the case at first, and had proposed a consultation with a view to operating; but his patient had strenuously refused his consent, and he determined to try and save the limb. He had formerly considered the healing the wounds as the result of the exclusion of the atmospheric air, and had laid great stress on that point, believing that inflammation and suppuration were not unfrequently induced by the custom of repeatedly uncovering and dressing the injured part. He now thought, that the beneficial result of the practice he adopted depended on the maintaining an equal temperature, sudden changes of which always caused irritation. This view he adopted from Mr. Crompton's paper on Burns and Scalds. It was important, he thought, to keep wounds at the temperature of the body, about 98°.

In the discussion which followed, the influence of atmospheric air was considered, and the beneficial action of solar light was also alluded to. No new point was elicited.

DECEMBER 3.

Private business occupied the attention of the Society on Monday last. It appeared that the trustees of their freehold property have died, without the appointment of successors, which ought to have been the case, and, consequently, the Society is without a marketable title to their property, and will be obliged to take proceedings in equity, to obtain the appointment of new trustees. Other business was also transacted; such as the decision to appoint the President for one year only, and also to remove the Society to a situation further westward. These alterations remain still to be confirmed by the Council.

CORRESPONDENCE.

MR. BOTTOMLEY AND THE CONFERENCE AT THE HANOVER-SQUARE ROOMS.

[To the Editor of the Medical Times.]

SIR,—I, by chance, had an opportunity of seeing the *Lancet* of the 1st inst., and, to my great surprise, I saw published certain resolutions forwarded by Mr. Bottomley, of Croydon, to that Journal, purporting that they had been formally agreed to at the "Medical Conference," held at the Hanover-square Rooms on the 20th ult.

I think the publication of those resolutions in the form in which they stand, is calculated to place the National Institute in a wrong position.

It was unanimously acceded to by the "Conference," that the part of the resolutions which expressed, "that the Institution as a third College would tend to the degradation of the mass of the Profession," should be erased.

I certainly think that all the reasoning and ingenuity of the *Lancet* and Mr. Bottomley can never dupe the mass of the medical profession so far as to make them fancy, that although we are now in the lowest state of degradation, that the establishment of an independent College, based upon those liberal principles advocated by the National Institute, can ever have a tendency to keep us so.

I have the honour to be, dear Sir,
Your very obedient servant,
Ulverston, Dec. 5, 1847. GEO. GIBSON.

"BLIGHTING INFLUENCE" OF UNIVERSITY COLLEGE.

[To the Editor of the Medical Times.]

SIR,—Allow me to offer some additional information on this subject, which I have been at pains to collect, in confirmation of the discovery of your far-seeing contemporary. The Professors and Medical Staff of University College have not been the only sufferers from the "miasma" of that place. As might be expected from its nature, the fatal influence has extended to officials of every grade. Witness the following losses among the College servants:—

Henry Morgan, beadle!
John Downie, successor to last!!
James Morgan, beadle!!!
James Hill, servitor!!!!
John Sherriff, porter!!!!!

Five valuable officers sacrificed within the short period of eight years!

Yours, &c., QUINUNCULUS.

GLYCERINE.

POUR ET CONTRE.

[To the Editor of the Medical Times.]

SIR,—The north-easterly winds of this week have, I have little doubt, reduced many to the condition of one of my servants, who showed me, a few days since, her wrists and arms, chapped and bleeding,—in fact, in such a state that she was unable to perform her ordinary house-work without great suffering. She had used all the ordinary remedies,—such as cold cream, lip-salve, goose-grease, &c., without benefit. Having obtained some glycerine, I directed her to smear her arms and hands with it every night. After using it two nights the roughness and chaps have almost entirely disappeared, the glycerine having acted,—to use her own expression,—like a charm. Although I do not think there is anything new in this application of glycerine, calling the attention of the Profession to a cheap and apparently sure remedy for a painful condition, especially affecting the lower classes, cannot fail to be of service.

I am, Sir, your obedient Servant,
HENRY J. M'DOUGALL.
24, Henrietta-street, Cavendish-square,
Nov. 29, 1849.

[To the Editor of the Medical Times.]

SIR,—Some weeks, perhaps now months ago, I saw the first notice of a never-failing remedy for deafness. I cannot tell you how delighted I was when I saw the announcement. I read the Article, and when I had done and closed my eyes for reflection, I saw the word *Glycerine* stand like a ghost in plain and prominent characters before my imagination. I then inquired the meaning. I had heard often of Glycyrrhiza, and remembered that I had often purchased it when at school. I said it could not be that, for it was spelled differently. Then I imagined it to be some new-fangled extract, perhaps alkaloid of Spanish juice. However, after I discovered, on rummaging over the knowledge in my knowledge-box, that it was something of a fatty nature,—law! how I stared then. Surely, thought I, it must be a wonderful sort of thing—I'll give an order for some. I began to reason on its effects, of the manner in which it effected a cure. Glycerine a fat—oh! I have got it. The cause of deafness must be a clogging of the wheels in the ear-machine, and his fat must be applied for the purpose of greasing them; and no doubt the idea must have been first obtained from the practice observed at railway stations, where porters go round with a quantity of yellow fat to put in boxes over the wheels of steam-carriages. The idea is splendid.

However these reflections were checked when I recalled my anatomy of the ear,—its physiology in health, its pathology in disease,—my hopes were at once frustrated, my joy turned into mourning, my faith lost, and I began to think of Morrison's pills, which were to do wonders; and it is reported of those who swallowed a sackfull at once, that if minus arm, or leg, fingers or toes, heads or brains, they were restored; so that those who had previously some time been useless in society, were made useful. At length I recalled the laughable song of Henry Philips, who invariably splits his sides in singing it, as no doubt many of your intelligent readers are aware. Had you not often told your readers, that you never published poetry, or at least poetical attempts, in your Journal, as beneath the attention of men of sense, and learning, and science, I would have attempted to have put the song in question in the form of a parody.

But, to be serious: I came to the resolution, before trying glycerine myself, I would see that others spoke favourably of it, and that it was a never failing remedy, if not in all cases of deafness, at least in some forms. The lapse of a short period has been the means of putting it, like many other potent remedies, into the shade; and it only remains now for the whole Profession to attend in deep mourning, with a view of burying it in oblivion. I trust that professional men, for their own reputation, will become, hereafter, too enlightened to run, like children after music in the streets, after every new remedy that is puffed into fame,

As glycerine, that queer,
Remedy for the ear.

I am, Sir, yours respectfully,
Nov., 1849. A REFORMER OF ABUSES.

COX, DAVIES, AND SILK, v. MIDLAND RAILWAY COMPANY.

[To the Editor of the Medical Times.]

SIR,—As this important case has been repeatedly brought before the public during the last two years, I trust you will afford me the opportunity, through the medium of your columns, of again bringing it before the public. As it has at last terminated in a manner which crowns the whole of the proceedings by executions being issued by the Company against the plaintiffs for their costs in defending this action, and by my having had an execution put into my house, and my goods and chattels virtually seized in payment of my share of such costs, amounting to 99*l.* 14*s.*, which I have actually paid, I think it only fair, that the Medical Profession and the public, whom I consider vitally interested by the decision upon this important case, should be made acquainted with their relative positions. The decision upon this case clearly shows, that the Company are not bound to provide medical aid for a passenger in case of accident upon their line of railway; that the servants of the Company have no authority to call in Medical aid; and should they so far overstep their authority, as to call in Medical aid, that the Company are not bound to pay the doctor; that the only person the doctor has to look to for payment, is the party injured, and, in the event of his being too poor to pay, the only chance the doctor has of being remunerated for his services is by the party injured bringing an action against the Company; and should he succeed in recovering compensation for the injury, still it remains to the honour of the party injured, whether he will pay the doctor. As it is now quite clear, that a medical man has not any claim against the Company, I should like to know what medical man, under such circumstances, unless he is fully assured of the respectability of the party injured, will volunteer his services to take charge of a railway accident, and run the risk of having a very severe and dangerous case under his hands for two or three months, probably at the distance of some three or four miles from his residence.

Since this has been before the public, I have repeatedly asked several of the porters at the different stations, and likewise several of the guards belonging to the Midland Company, what they should do in case of accident? The answer I have invariably received has been, that they did not know what to do; that they should do nothing, but leave the parties injured to their fate.

It appears to me a very hard case, that three humble individuals, suing a great and powerful Company for what was fairly and justly due to them for services rendered to an unfortunate individual who had met with a most serious and dangerous accident upon their line of railway, and whose life must have fallen a sacrifice, but for the most prompt and efficacious medical aid having been rendered to him, and which accident was clearly shown to have arisen from the carelessness of the Company's servants, should not only be deprived of what was justly due to them, but likewise be called upon to pay the costs of the Company in defending the action, more especially when it is taken into account that this case ultimately terminated upon a point of law, which I believe had never before been mooted since the introduction of railways, namely, the non-liability of Railway Companies for orders actually given by their own servants.

I am, Sir, yours &c.,
J. DAVIES, M.D.
Blythe College, Coleshill, Nov. 1849.

P.S. For particulars see *Daily News*, January 18; the *Times*, January 30; and *Aris's Birmingham Gazette*, February 5, and March 19, 1849.

MIDWIFERY.

[To the Editor of the Medical Times.]

SIR,—For the advantage of your youthful readers, I send you the following case. It illustrates the observations of a Dublin writer on the advantage of preserving the membranes entire in cases of premature labour, where there may be hæmorrhage, while yet there are pretty strong pains, by which there is reason to expect the expulsion of the entire ovum by patiently waiting, when the woman's strength is not much reduced by the hæmorrhage.

The patient, seven months gone with child, sent for help on account of some flooding. When the doctor arrived the membranes protruded at each pain, but still every time there was slight hæmorrhage. In order to put a stop to this discharge, and in the hope of expediting the labour, the membranes were ruptured.

Immediately the pains ceased, but not so the bleeding; and after waiting an hour, and the woman had suffered a considerable loss, the hand was obliged to be introduced, and the child turned and brought away, a painful and somewhat difficult operation at the seventh month.

The error in this case lay in not letting well alone. As the pains were pretty strong, and the membranes protruded well, in all likelihood the whole ovum would have been expelled in a short time, and thus averted the danger and difficulty resulting from the cessation of pains which immediately took place when the membranes were ruptured, and the stimulus of the waters taken away.

The Dublin doctor insists upon the advantage of allowing the membranes spontaneously to break in most cases of natural labour; the danger of after-hæmorrhage thus being greatly lessened by the more favourable separation of the placenta. Instead of the pains coming on better by the escape of the waters, they are often stopped for hours, to the detriment of the mother, and sometimes the destruction of the child.

Yours, &c.,

SARSUR.

[Sarsur has favoured us with his name.—ED. *Med. Times.*]

THE CONTAGIOUSNESS OF CHOLERA.

[To the Editor of the Medical Times.]

SIR,—I shall not venture upon the Herculean task of trying to convince Mr. Leithead of the contagious nature of cholera, neither shall I try to contravert the practical notions of the disease he has acquired in so wide a field of observation as the Old Surgeons' Hospital at Edinburgh; but I shall merely add in this communication a sequel to my last hasty scrawl, in order to illustrate still more forcibly the inferences I then drew from but a limited observation of the disorder.

The population of Bulwell is about 3,700, and the houses in which the disease *broke out first* look upon a grass close in front of my residence, and behind them there is also an open space sufficient for a thorough ventilation. Several weeks previously to the outbreak I had attended to the sanitary condition of the yard, and had the nuisances removed and a privy erected.

Cholera, when it began here, had not become *universal* in the village; not *even dreamt of*; for when the alarm was sounded I opened my surgery to every applicant, and a *slight tendency* only was evinced by the villagers to diarrhœa. I may, I think, fairly presume from this circumstance, that the *spread of the cholera* did not depend upon an epidemic origin, for no other parts of the village were similarly affected, but solely resulted from contagion.

I do not, I never have denied the *epidemic nature* of the complaint, but I do assert, after a most attentive observation, *that there is a cholera poison generated in cholera patients*, and *generating* in its turn; *inherent in* the bodies of those who die, *adherent to* the discharges of those who live, *capable of being* destroyed by disinfectants, and *hanging round and hovering over*, as a halo, the place where it originates. *Attacking most powerfully* those exposed longest to its influence, deranging slightly those imbibing it in a diluted form.

It is not because five, six, or seven persons in a room with a cholera patient sometimes escape, you are to argue the non-contagiousness of the complaint, for, in small-pox, this very frequently happens, yet no one denies the propagandism of it as in measles and scarlet fever, *cum multis aliis*. It would, indeed, be hard upon mankind for such a rule to become general, and under this code the human race would soon be annihilated.

Does Mr. Leithead and other non-contagionists ever employ disinfectants in cholera cases, or is he so wedded to his theory as to neglect proper precautions against the enemy?

The only way to arrive at the truth of this highly-important proposition, is to collect together into one focus the experience of the Poor-law Medical Officers in country districts, who have witnessed the epidemic, and to cull from their reports every fact which will tend to elucidate the subject. Such a task I would willingly undertake if gentlemen would communicate with me, and I would lay every opinion before your notice, whether or not they coincide with the views I have advanced.

The sequel to my first letter is as follows:—Mrs. Dawse, the woman who attended nearly every cholera case in the row before alluded to, nursed her husband, and when in a state of collapse she hung over him, and as it were, sucked in his poisoned breath. Her diligent attention saved him, but in a few days after she was seized with the disorder and died rapidly of it.

The only *house* which the pest avoided in the row, was the house of a man recently returned from prison, who did not communicate with his neighbours.

A drain, running from these houses and emptying itself into the road sewer, conveys the discharges to a distance, and a person whose door opens just at the junction, had a most severe attack of diarrhœa.

In the case of Robert Slamforth, through the kindness of a reverend gentleman, the patient's bed and bedding and clothes were destroyed *instanter*; the house on Sunday was whitewashed; strongest bleaching liquor was poured about; and I believe the disease stopped in this house from the extreme caution taken to destroy everything which could hold contagion. So this goes still further to substantiate my point.

Again. Mrs. Osborne, complaining of diarrhœa, comes to my surgery, and passes immediately in front of the before-mentioned houses. She goes home; is attacked with genuine cholera. Next morning her child, Anne, is seized, and dies in eight hours, and another child is taken very ill. The discharges from these patients were carried out at the back door, and most imprudently thrown on an ash heap, *immediately under the sleeping apartment* of a man named Wildjust, who becomes affected, and dies in a horrid state. These cases are in a different part of the village. The man who laid Wildgust out goes home and gets into bed, and in the night I am called up to his wife with evident symptoms of incipient poisoning, which is carried off, however, by a dose of castor oil and saline. A woman, too, washed Wildgust's clothes, and she, going home to her family, conveys it to her son, who is also suddenly seized, as if slightly affected with the poison—having cramp in the stomach, slight diarrhœa, and headache.

Whilst I was at Osborne's, a shoemaker came in and looked at their dying child for some time, when we were trying to get warmth into it. He returns home, and the next case is *his wife*, who recovers after a most violent attack. I do not wish these instances to be taken for more than they are worth; they would be worthless if others, *like Mr. Moyle*, could not bring forward similar cases; and had I time I could also bring capital proof of a like occurrence in Ratcliffe, a village about four miles the other side of Nottingham, in which the disease, when it once commenced, ran the gauntlet as with us.

I trust I have not encroached too much on your valuable space, affected great things when I have nothing to boast of, added no erroneous theory to the domain of medicine, and excited no ill-will towards me from those opposed to my deductions.

I remain, Sir, your obedient servant,

ALFRED EBSWORTH.

THE PROXIMATE CAUSE OF EPIDEMIC CHOLERA.

[To the Editor of the Medical Times.]

SIR,—Reading Dr. Toogood Downing's paper, which appeared before the London Medical Society of London on the 12th inst., on "The Proximate Cause of Epidemic Cholera," I was glad to find that he considered *spasm* as the chief cause of all the more grave symptoms of the disease, and this is also my humble, though firm belief.

Shortly after the cholera left this locality, and when every circumstance connected with this disease was fresh on my memory, I made a few short notes, which, as they agree in such a singular way with Dr. Downing's views, may not be unworthy a corner in your Journal.

My observations were, that the poison or exciting cause of cholera, whatever that may be, appears to act in the first instance through the medium of the nervous or the muscular system, and through that of both on the circulation. A nervous shock is produced, and muscular spasm is the result of such shock.

This spasm affects both the involuntary as well as the voluntary muscles. It extends to the muscular coat of the stomach, producing pain, vomiting, &c.

And it would appear also to extend to the muscular coats of the arteries, and even the bronchial tubes—producing in the one set of vessels, unequal diminished circulation, and in the other more or less dyspnœa and imperfect oxygenation of the blood in the lungs, leaving nothing but a fluid of too thick a nature to circulate, and too impure to be of any service in the economy. Hence, none of the usual secretions—urine, perspirable matter, bile, &c.; for, though in the majority of cases this fluid has been found in the gall bladder, yet probably it was secreted long before the attack of spasm occurred, which detained it in its reservoirs.

I also quite agree with Dr. Downing in supposing the serum of the blood to be squeezed out through the delicate coats of the blood-vessels, by the same spasmodic canal.

Dr. Downing mentions as a remedy the dilute hydrocyanic acid. I can certainly vouch for its good effects in checking obstinate vomiting, having used it successfully when all other means failed in arresting the irritability of the stomach.

I fear, Mr. Editor, I have now trespassed on your space too much, but the importance of the subject I thought would justify me in giving my support, weak though it be, to Dr. Downing's spasmodic theory, which appears to me a very rational one.

I have the honour to be, Sir,

Your obedient servant,

SPASM.

Portsmouth, November 25th, 1849.

EXAMPLE OF SYMPATHY OF PARTS.—DEATH ON THE FOURTH DAY FROM A KICK ON THE LEG.

[To the Editor of the Medical Times.]

SIR,—On the morning of 3rd November current, I received a call to attend a boy of eight years, who, the messenger, a young lad, most truthfully, as it turned out, said, had received a kick on the leg, and that "the hurt had flown to the brain." On arrival, about 10 a.m., at the boy's residence, six miles distant, I found the father and other relatives assembled around the bed; the boy being quite unconscious of what was passing. The pupils of the eye were largely dilated, and insensible to the stimulus of *light*, which I still further proved by passing a lighted candle and other objects before the eyes. Pulse under a hundred, and presenting nothing unusual. Respiration and heat natural; the features rather pale than otherwise. On being loudly spoken to he seemed unconscious, and gave no signs of hearing. Left leg, on the inner side, about four inches below the patella, around the calf, rather tense and swollen, but not remarkably so; and there was scarcely any perceptible discoloration, or mark of injury. Pressure gave no signs of pain. From the father, a small farmer, I learned that, about noon on the Wednesday preceding, the boy had received a kick on the calf of the leg from a schoolfellow about his own age; that he had not remained at school, but limped from Blair-adam home (to Chapel of Lochore, a farm on the estate of Lochore, the property of the son of the poet, the late Sir Walter Scott), a distance of two and-a-half miles. Being put to bed, the pain somewhat abated. During the night he was restless and uneasy. As the marks of external injury were so trifling, no importance was attached to it, and a cold water cloth was the only remedy employed. On Friday, he was seen by a practitioner, to whom, from the external appearances, the injury appeared of little consequence, and an attempt to force him to swallow some laxative powders, was succeeded by another nervous fit, lasting fully half an hour; the father adding that, though I repeatedly tried, with a metallic spoon, "I could not force open his jaws." A purgative enema then given, I was told, had a pretty full effect. During that afternoon, the delirium, which was occasional on Thursday, was almost constant. Such, so far as I could learn from the parents, and from a clergyman resident under the same roof, who frequently saw the boy, was the brief history of this case, previous to my seeing him, not quite three days after the receipt of the injury.

In this state of matters, after close cropping the hair, cold water cloths were applied over the vertex, and almost immediately thereafter, six leeches, being all that were at hand, were applied to the swollen part of the limb. And it was observed that, ere the leeches had dropped off, the boy asked for a drink of water, which was taken in small quantity. At this period, my attention being directed to the leg and the leeches, I regret that I omitted to observe whether there was much, if any, difficulty in swallowing. At the end of about an hour consciousness was partially restored, and the pupils had also somewhat recovered from their state of extreme dilatation.

Fomentations of hot-water cloths to the leg for four hours; to be followed by a large poultice, and to be frequently renewed. In the afternoon, if the

incoherence appeared to increase, three or four leeches to the temples. A purgative enema, q. p.

Giving such general directions as I thought necessary, I then left him, having expressed to the parents an unfavourable opinion of the case. Next morning, (Sabbath,) when preparing to repeat my visit, I received notice of the boy's death, which had taken place at 3 a.m., being eight hours within four days from the receiving of this apparently trivial injury, the early neglect of which, it is more than probable, contributed much to hasten the fatal result. That the kick was not one of great severity, is rendered probable by the extreme youth, only *eight* years, of the boy who inflicted it. The distance, and other circumstances, prevented a *post-mortem* examination. On inquiry at the clergyman above-mentioned, I learned that, with the exception of *once*, about two hours before death, when he asked for a urinal, he showed no signs distinctly indicating a return of consciousness; and further that, in the course of the Saturday afternoon, there was marked increase in the swelling of the limb.

In Surgery, the doctrine of irritation, or *sympathy*, teaching the immediate and remote effects of injuries; in what manner nature restores them, on the one hand; and, on the other, the mode in which apparently trifling accidents prove destructive, is universally acknowledged; but the real nature of sympathy is at present, and probably ever will be, beyond the reach of the human understanding, though the manifestations attending it are subjects deserving of inquiry, and of the utmost importance in practice. A writer in an able series of Papers, "On the Causes of Sudden Death," has remarked, that, "at the same time, it will be borne in mind, that a purely local affection scarcely exists, and that all parts of the animal economy are so intimately connected, at least in man, the perfection of organization, that no part can suffer, without the rest sharing in the distress." And it is not undeserving of notice, that the Apostle Paul (1 Cor. xii. 20, 25, 26) has, with equal beauty and accuracy, described the harmony uniting the parts as one, "That there should be no schism in the body; but *that* the members should have the same care one for another.... And whether one member suffer, *all the members suffer with it.*"

ROBERT ANNAN.

Kinross, November, 1849.

ON THE EPIDEMIC AND ENDEMIC NATURE OF THE CHOLERA.

[To the Editor of the Medical Times.]

SIR,—As a contributor and subscriber to the *Medical Times*, I must confess that the coarse and very unjust manner in which my name was adverted to in the pages of your last Number disgusted me exceedingly.

What have I committed that the said, unknown to me, slanderer dares to use the words "fallacious," "inconclusive," and vague, as tacked to my name?

I have not yet chanced to read anything issued by the Board of Health from Gwydyr House, upon the epidemic or endemic nature of the cholera, which I now regret, as any observations under the revision of my highly-qualified and talented friend, Dr. Southwood Smith, must command at all time the serious attention of all members of the Profession. Nevertheless, have not I, the individual who had the very painful duty to perform, from my position, the advent of the cholera into these islands, a right to express my convictions, from actual, most extensive experience, my impressions as to the nature of the pestilence in question? Of one thing, Mr. Editor, you will accord this to me.

Let any clear-headed, honourable member of the Profession read carefully from page 108, Part X., of my friend Dr. Copland's valuable "Dictionary of Practical Medicine," and he will find abundance of proofs of the endemic nature of the cholera, though it is needful to remark, *en passant*, that I had dismissed from my mind all that I had read previously upon this subject.

I am sorry that I have been so prolix, holding, as I always do, to the old maxim—

"Dum brevis esse laboro obscurus fio."

I remain, Mr. Editor,

Your most obedient humble servant,

W. REID CLANNY, M.D.,

Kt. Com. St. John of Jerusalem, &c.

Sunderland, Nov. 26, 1849.

GOOD PAY.—In Aberdeen the streets are swept every day at an annual cost of 1,400*l.*, and the refuse brings in 2,000*l.* per annum, the manure selling for 1,730*l.* This is, indeed, a premium for saving life.

ROYAL COLLEGE OF SURGEONS.

The necessary examinations for the "Fellowship" of this Institution commenced on Tuesday last, and were continued until Friday. The number of gentlemen who presented themselves as candidates for the honour amounted to twenty-two. The following were the questions in Anatomy and Physiology submitted to the senior candidates, (members of eight years' standing and upwards,) viz.:—

1. Describe the structure of the knee-joint, the movements which it is capable of performing, and the muscles by which these motions are effected.

2. Describe the use of the several valves of the heart, the order in which the auricles and ventricles contract and dilate, and the state of the heart when its pulsation is felt on applying the hand to the exterior of the chest.

3. Describe the diaphragm and other muscles employed in respiration; and describe their agency in the respiratory process.

4. Describe the course of the urethra, its dilatations and contractions, its structure, and the parts which surround it or are in its immediate vicinity.

5. Describe the differences of form and structure in the intestinal canal, and the functions attributed to its different parts.

6. Describe the changes which take place in the air received into the lungs, and in the blood circulating through the pulmonary capillaries during respiration.

The following are copies of the questions submitted on the same subjects as the above, to the junior candidates, viz.:—

1. Describe minutely the structure of the lungs, especially that of the air-tubes and air-cells, and the relation of the latter to the pulmonary capillaries. Describe also the movements, both in the lungs and in the parietes of the chest, which concur in order to effect the change of air in respiration.

2. Describe the ordinary chemical changes which occur during breathing in the blood and air, and the variations in those changes, which do not imply a deviation from health. State, also, the connexion of these changes with the temperature of the body, and with the maintenance of an uniformity of temperature in man and other warm-blooded animals.

3. Describe the movements of the heart, and explain the causes and conditions under which they are produced. State, also, the influence which the nervous system may be supposed to exert on the movements of the heart, both on those which are regular and ordinary, and on those which are irregular and occasional.

4. Describe the structure of the medulla oblongata, the connexion of its columns and fasciculi with the cerebrum, cerebellum, and spinal chord, and the origin of the nerves which proceed from it.

5. Describe the functions of the medulla oblongata, and of the nerves which proceed from it.

6. Enumerate the muscles which serve to erect the body and to maintain it in the upright posture, and the action of these muscles when so engaged. Describe also the action of the muscles which are especially exerted to balance the body in standing on one leg and at the same time on tip-toe.

N.B. Answers to any four of these questions will be accepted as sufficient, provided always that they are *accurate and adequate*.

The following questions in Surgery were submitted to the senior candidates on the 6th inst., viz:—

PATHOLOGY AND SURGERY.

No. 1.

1. In the two forms of Erysipelas, simple and phlegmonous, what are respectively the principal symptoms; what the course and termination; and what the treatment constitutional and local?

2. What is the treatment to be adopted in a case of wound of the Brachial Artery occurring in venesection?

3. Describe the treatment of Retention of Urine from stricture in the urethra, and the consequences which are to be apprehended when the retention is not relieved.

4. Describe the progress of a carbuncle from its commencement to its termination, when not arrested by treatment. Describe also the treatment, both constitutional and local, by which its progress may be arrested?

5. Describe the characters of Dislocations of the Shoulder-Joint, and the modes of reduction.

6. What is the effect of Opium on the system? What are the principal preparations which are in use? And what are the doses of each?

N.B. Answers to any four of these questions will be accepted as sufficient, provided always that they are *accurate* and *adequate*.

The following questions were submitted, on the same occasion, to the junior candidates, viz.:—

PATHOLOGY AND SURGERY.

No. 2.

1. Describe the nature and physiological consequences of Asphyxia, its causes, especially those depending upon irrespirable gases, and the more important remedial measures required.

2. State what is known with regard to the pathological changes in the blood.

3. Describe the principal varieties of the pulse, and in what respect they may be severally regarded as diagnostic of morbid conditions of the system.

4. Describe the morbid changes which take place in the urinary organs from long-continued irritation of the bladder or urethra; and explain in detail the causes of such changes.

5. Describe the different methods by which a calculus may be removed from the bladder, and what the circumstances under which they may be severally indicated.

6. Describe the various circumstances of surgical interest which attend a case of wounded intestine.

N.B. Answers to any four of these questions will be accepted as sufficient, provided always that they are *accurate* and *adequate*.

HEALTH OF LONDON DURING THE WEEK ENDING DEC. 1.

A considerable decrease is still shown in the number of deaths as compared with the average of five years, amounting to 231; the number of deaths, however, showing a slight increase on those of the five weeks previously. This increase appears to have taken place in deaths caused by diseases of the respiratory organs. In epidemic diseases the Returns give 173, while the autumnal average is 307. Cases of typhus have declined to 35, being 21 under the average; from cholera only 1 death is returned, the average being 8; this case occurred in the south-west division of the City, to a female, aged 27; the deceased sunk under debility, after two attacks. An infant of three months died of diarrhœa, of four days' duration, in 5, Whitting-street, Waterloo-road. The Registrar says:—"The grandfather of the deceased is also suffering from diarrhœa and sickness. The house is well drained, but it is in an unwholesome locality. The informant said that the water was dreadfully bad, and scarce fit to be used, which she imputes to the rotten state of the water-butt."

The mean temperature on Monday was 34·2; on Wednesday it fell to 26·1 (less than the average by 17·5); and rose at the latter end of the week to 40·0; the result for the week is a minus on a seven years' average of 9·1. The mean height of the barometer was 29·803. The reading increased from 29·25 in. at the beginning of the week to 30·03 by 9 h. p.m. on the 27th; it decreased to 29·69 by noon on the 30th; it increased to 30·00 by 3 p.m. on the 1st Dec., and then decreased to 29·96 at the end of the week. Positive electricity was indicated on Sunday, Monday, Tuesday, Wednesday, and Saturday; nothing shown on other days. The sky was overcast generally throughout the week with cirrostratus.

Appended to the present return is a valuable table, giving the population of the districts and sub-districts of London in 1841 and 1848; the deaths from cholera in the last thirteen weeks of 1848, and in the forty five weeks of 1849; the proportion of deaths to 10,000 inhabitants, and the number of inhabitants to every death.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Dec. 1, 1849.

Causes of Death.	Total.	Average of Five Autumns.
All Causes	931	1162
Specified Causes	928	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	173	307
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	45	49
Tubercular Diseases	170	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	118	125
Diseases of the Heart and Blood-vessels	34	40
Diseases of the Lungs, and of the other Organs of Respiration	104	214
Diseases of the Stomach, Liver, and other Organs of Digestion	60	65
Diseases of the Kidneys, &c.	8	11
Childbirth, Diseases of the Uterus, &c.	12	10
Rheumatism, Diseases of the Bones, Joints &c.	6	8
Diseases of the Skin, Cellular Tissue, &c.	...	1
Malformations	8	4
Premature Birth and Debility	20	23
Atrophy	24	18
Age	45	57
Sudden	5	12
Violence, Privation, Cold, and Intemperance	11	36
Causes not Specified	3	4

The following is the number of Deaths occurring from some of the more important special causes:—

Apoplexy	30	Heart	28	Phthisis	134
Bronchitis ...	60	Hooping cough	23	Pneumonia ...	94
Cholera.........	1	Hydrocephalus	24	Scarlatina	37
Childbirth	4	Influenza	...	Small pox	5
Convulsions...	38	Liver	10	Stomach	4
Diarrhœa	17	Lungs	9	Teething	8
Dropsy	20	Measles	26	Typhus	35
Erysipelas ...	5	Paralysis	21	Uterus	[illegible]

BIRTHS AND DEATHS.

	Births.	Deaths.	Births over Deaths.
Males	668	489	179
Females	623	442	181
Total......	1291	931	360

METEOROLOGY OF THE WEEK.

Day.	Mean of Barometer.	Mean of Thermometer. Dry.	Ditto. Dew Point.	Difference between the Mean Temperature of the day and the same day on an average of 7 years.	General Direction of Wind. A.M.	General Direction of Wind. P.M.	Amount of Horizontal Movement of the Air.	Rain in Inches.	Electricity.*

MEDICAL NEWS.

Apothecaries' Hall.—Names of Gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, 29th Nov., 1849: — Samuel Reynolds, Dubach; George Edwin Gains; Edward Humphrey Paget, Leicester.

Obituary.—On Sunday week, Mr. John Spencer Birch, Surgeon, of Blackburn. On the 30th ult. at Brompton Crescent, Thomas Gunning, Esq., Inspector-General Army Medical Department, aged 74. At the Cape, Dr. Deas, Surgeon-Superintendent of the Neptune, convict ship, and Dr. Munro, Surgeon of the Castor. On the 27th inst., at Longfleet, near Poole, Dorset, Robert Carruthers, Esq., M.D., Royal Navy. On Sunday last, at No. 12, Grove, Hackney, Mr. Edmund Sheffield, surgeon, aged 71. On the 3rd inst., at Burwood-place, Hyde Park, Louis Truefitt, Esq., Surgeon.

Naval Appointments.—Dr. Corbett, Assist.-Surg. to the Centaur, appointed to the Snap Tender; Mr. Walling, to be Assist.-Surg. to the Pluto; Howard R. Banks, Esq., to be Surgeon to the Terrible steam-frigate. Dr. Gibson, to be Surgeon-Superintendent of the Neptune, convict ship. Assistant-Surgeon King, to be Surgeon to the Euridice, vice Gibson, appointed to the Neptune. Assistant Surgeon Elliott to be Surgeon to the Castor, vice Dr. Munro, deceased.

Cholera in America.—The cholera has again made its appearance on the Mississippi river. Two steamers, both from New Orleans, had arrived at St. Louis with immigrants; on board one of these vessels there were thirty cases, seventeen of which proved fatal before arrival at that city.

Cretinism.—The Minister of the Interior lately presented to the King of Sardinia, the members of the Commission lately appointed in 1845, by His Majesty's father, the late Charles Albert, to study the causes and remedies of "cretinism." The Commission has made a report on the subject. The King was much affected when he learnt, from a perusal of the report, that more than 7,000 of his subjects were smitten with this disease, which is spread over 22 provinces of the States of Sardinia.

Munificent Bequest.—The late Mr. Lewis Morris Cuthbert, of Lyon Terrace, Maida Hill, has bequeathed 3,000*l.* to the Hospital for Consumption at Brompton, 1,000*l.* to the Royal Free Hospital, 500*l.* to University College Hospital, and 100*l.* to the Western General Dispensary.

The funds of the Royal Isle of Wight Infirmary have lately been increased by the donation of 1,500*l.* stock, under the will of the late Rev. George Atwick, M.A., who has devised 6,000*l.*, 3½ per cents., to be divided among four casualty hospitals.

Dietetic Relief to the Sick Poor.—The Board of Guardians of Birmingham have recently decided, on the suggestion of their chairman, that the power of ordering food to out-door paupers who may be unwell, at present vested in the parish surgeons, should be withdrawn, as it appeared that very injudicious orders had been made in several instances; one old woman, who was dying, having had 3lbs. rice, 1lb. sugar, and ¼lb tea ordered her at once. These Guardians require a little pressure from without to teach them humanity. It is monstrous to deprive the parish surgeon of the power of ordering food for a sick pauper—it is often, very often, more necessary than physic, and its refusal may lead to loss of life. In such a case the coroner should have early notice, and then, probably, the verdict of the jury may bring these gentlemen to their senses.

Cholera in Siam.—This pestilence has been committing fearful ravages in Siam. A few cases occurred on the 7th of June, but by the 29th it had increased so much that eighty bodies were taken to a single "wât" for burning. Subsequently the number of deaths was so great that it was found impossible to burn all the bodies; many were buried, and multitudes thrown into the river just as they died. In many of the "wâts," nearly 400 were buried in a day. They were brought and laid in piles, and fuel applied, when they were consumed like heaps of logs. During the 19th, 22nd, and 23rd of June, from 2000 to 3000 died daily; at the end of twelve days it was known that more than 20,000 had fallen victims. It has abated since, but by no means ceased. The mortality has been less among the Chinese than among other classes in Bang-Kok.

TO CORRESPONDENTS.

We have received a letter from Mr. Theodore Davis, of Tickenham, near Bristol, and one from Mr. Ogilvie, of Ridgeway-house, in reference to our Editorial Article on "The Gloucestershire Private Madhouses." Both our Correspondents complain of the "one sided" nature of the Report of the Chairman of the Board of Visiters, Mr. P. B. Purnell; and Mr. Ogilvie says, "there was not one word in it worthy of credence or regard." We have no wish whatever but to see justice done to all parties. The proprietor of a private asylum has committed to him an important trust. He is liable, we are aware, to suffer from misrepresentations, and hence it is the duty of visiters to see that even-handed justice is administered. If Mr. Purnell's "Report" is such a document as our correspondents represent it, we are astonished that the magistrates of the county of Gloucester should have given credence to it, or, as Mr. Ogilvie states, "should support him." It is our wish, that the proprietor of Ridgeway-house may entirely set himself right with the profession, the public, and the county magistrates; and we shall not be backward in advocating his cause where truth requires.

"Dr. Clay's Operation."—H. A. complains that, in our recent notice of Dr. Clay's work, our Reviewer only takes cognizance of three cases, leading to the belief that these are the only cases operated on, whereas there are, altogether, forty-one cases, including five exploratory operations. Of true ovarian tumours there are thirty-three operations, and twenty-three of them are successful. Our Correspondent states, that the Reviewer's chief objections to the operation are the uncertainty of diagnosis between a tumour of the uterus and a diseased ovary, the extent of the adhesions, the magnitude of the pedicle and its vascularity, and the number of blood-vessels extending from the diseased ovary to the contiguous viscera. These H. A. considers no valid objections, as, in many other diseases requiring operation, the diagnosis is often uncertain. He says that once he was prejudiced against the operation; and thinks that a patient of his, an interesting female, labouring under ovarian disease, and who was not operated upon, might have been saved had this been the case. He also mentions the case of a married female, in whom the adhesions were very extensive, and required great care at the time Dr. Clay operated, to separate them. The patient perfectly recovered. H. A. thinks that any person coming to so hasty a conclusion, as our Reviewer, should have suggested some other resource. We congratulate Dr. Clay on the success which has attended his operations; but we are compelled to state, that the experience of other eminent Surgeons is not in favour of the large incision.

We propose next week to commence a series of eight or ten Clinical Lectures on some Diseases of the Heart and Lungs, by Dr. Parkes, Professor of Clinical Medicine at University College. We have also pleasure in announcing a series of papers on Puerperal Mania, by Dr. Lightfoot.

"Dr. Spencer Thomson, of Haunton, Burton on-Trent, has favoured us with a paper "on the Vesicles of Torule in Urine," with illustrative drawings. We shall avail ourselves of the earliest opportunity of inserting the communication.

A Correspondent has forwarded to us the following, and justly asks, "How can we ever become respectable when such documents are issued and no notice is taken of them by members of the profession?—'Dr. ———, Surgeon, begs respectfully to acquaint the inhabitants of Lanchester and its vicinity, that he has commenced practising as surgeon and accoucheur at Lanchester, and trusts from the knowledge he has acquired in his profession to merit the support of the neighbourhood —November, 1849.'"

"L. M." asks:—"Can you inform me, or, if not, would Mr. M'Dougall state, which is the best method of applying the nitrate of silver to the urethra in cases of spermatorrhœa?"

[We shall be obliged to Correspondents who apply to us upon this subject to address their inquiries to its Professors. Mr. M'Dougall has published a work upon Spermatorrhœa, which L. M. will probably consult with advantage.]

"Mr. Yearsley's" reprint of a new mode of treating diseased Tympana by the application of the hydrated cotton, constituting an artificial tympanum, has been received. We hope to publish, in an early Number, a communication from "Mr Harvey," on "The Artificial Tympanum," to which we may, probably, append some remarks.

"Mr. Marshall, of Islington," must have laboured under some strange delusion when he forwarded the communication and testimonials with which he has honoured (?) us. His papers lie at our office; he can have them on application.

"Mr. H. P. Fuller" will find that it is his mistake, not ours.

The request of our friend at Birmingham will be attended to.

We shall endeavour to publish Mr. McClure's paper next week, and send "a proof," as requested.

We regret that the Report from University College Hospital reached us too late for this week's number.

"A Reader" asks, "What is a deadly poison?" One that proves quickly fatal in small doses.

"G. B., Suffolk," is doubtful as to the amount of fibrine in the human blood. It forms about a 1-500th part.

"Civilian."—"Is a gun-shot wound what may be denominated contused?" Yes.

"Truth Seeker."—"Can a child born before the seventh month live?" Cases have been recorded of instances of this kind. One was published in the "Medical Times" about eighteen months ago.

ORIGINAL LECTURES.

CLINICAL LECTURE ON SOME DISEASES OF THE TESTIS.(a) DELIVERED AT UNIVERSITY COLLEGE HOSPITAL,

By R. QUAIN, F.R.S.,
Professor of Clinical Surgery in University College, Surgeon to University College Hospital.

[Reported by EDMUND CARVER, M.R.C.S., lately House-Surgeon to the Hospital.]

We have lately, gentlemen, received into our wards two persons suffering from different forms of disease of the testis, to whose cases, and if there should be time enough, to that of an out-patient who is under treatment for disease of the same part I wish to direct your attention to-day. This is the history of one of the cases abridged from the report in the case-book.

A. Tucker, aged 30, admitted into the hospital 30th January, on account of an enlargement of both testes, is of stout conformation; has usually had good health, interrupted only by two or three attacks of gonorrhœa and syphilis. Of the latter disease he has still some indication in a few livor-coloured spots or stains upon the thorax. He has been in the habit of drinking large quantities of beer daily.

About fifteen months ago, immediately after jumping from a wall twelve feet high, and having been previously, for a considerable period in good health, the patient felt a sudden pain in the back. A short time afterwards, he can't say how soon, he observed a swelling of the right testis, small at first but quickly increasing, till the gland reached the size of a small gourd. He states that the swelling has remained stationary for the last four months. Now it measures ten inches in circumference, and six from the upper to the lower end. Upon the anterior surface the skin is reddened, in consequence of the application of iodine previously to his entering the hospital. The swelling is generally hard, but it yields in a slight degree to the pressure of the finger; and upon the fore part, near the upper end, fluctuation is felt to about the extent of a shilling. The reddened skin is adherent to the subjacent tumour, and it is at the upper end of this that the fluctuation exists. Not a trace of the epididymis is to be distinguished. There is apparently a degree of thickening of the vessels of the cord, and the vas deferens feels somewhat enlarged. No pain is caused upon any of the parts being manipulated.

Some three months since the left testis began to swell much in the same way as the other; th which it is now considerably smaller. The gland is hard to the touch over its whole surface; it is of uniform density; but there is a degree more of firmness at the posterior part in the situation of the epididymis than elsewhere. The skin on this side is natural; it has no connexion anywhere with the tumour. The vessels of the cord and the vas deferens are slightly thickened, but they do not seem at all in an unhealthy condition.

A few veins are plainly seen upon the posterior surface of the scrotum. They are not, however, particularly enlarged or numerous; there are none distinguishable on the anterior aspect of the same part.

Sharp shooting pains are occasionally felt in the testes, and extending upwards to the groins. These uneasy sensations are usually but momentary in their duration.

The patient states that his health has been impaired since the commencement of the disease, and that he is now less vigorous, less able to do his usual work than formerly. He has, too, a feeling of sickness; his face is sallow—"has lost colour," he says. The conjunctivæ are tinged yellow, and his tongue is covered with a yellowish creamy fur.

There is no tenderness on pressure in either iliac fossa; and there is neither tumour nor any appearance of fulness in the same situation, or in any other part of the abdomen. But the right rectus muscle is felt to be rigid towards its upper end. A degree of uneasiness is likewise produced by pressure over the muscle in this situation; at the same time the sound elicited by light percussion, made near to the margin of the thorax, is quite clear, except in the neighbourhood of the sternum. The corresponding part of the left rectus is notably different from the muscle of the right side. It is soft and yielding, and no uneasy sensation is occasioned by pressure upon it.

Observations.—The first object we have to attain in this case, as in all other cases, is to determine the nature of the disease, for the conclusion arrived at respecting this point determines our after-proceedings. Any morbid condition of the scrotum itself is easily distinguishable by the appearance and feel of the part, the skin and subjacent cellular membrane being involved; and as these parts are free from tumefaction in our patient, our attention will be restricted to the diseases of the two subjacent structures, namely, the testis and its serous investing membrane, the tunica vaginalis. It is necessary we should refer to both these parts, because certain of their diseases are liable to be confounded.

Inasmuch as the diseases of the gland itself are more or less solid, while the serous membrane, wherein a morbid state, contains fluid, we have in the first place to ascertain whether the tumour is due to the presence of fluid or to a solid deposit—in other words, whether it is a hydrocele or a sarcocele. In ordinary cases, hydrocele is easily distinguished from other diseases by its translucency, which is rendered apparent in the way commonly practised, namely, by the light of a candle in a darkened place. But the diagnosis becomes occasionally difficult, the difficulty depending on these circumstances, viz.:—that the hydrocele may lose all translucency in consequence either of the fluid becoming opaque (as by the admixture of blood), or the investing membrane being thickened to such a degree as no longer to transmit light. And should these changes, namely, the increased thickness of the membrane and the alteration in the colour of the fluid, be present in the same case, the difficulty of the diagnosis is much augmented, for the hydrocele thus loses its best distinctive character, while, on the other hand, all the remaining diagnostic marks (its smoothness, its shape, its elasticity) may be very closely simulated by disease of the gland itself. I cannot, perhaps, better prove to you how obscure the diagnosis may become than by mentioning that I saw the late Mr. Liston, in this hospital, extirpate a hydrocele under the belief that the tumour was a diseased testis. I happen to be aware, too, that Mr. Liston had previously inquired with some care into the nature of the disease, for when I grasped the tumour to assist in the operation (having then seen it for the first time), I remarked how much it had the smoothness and shape of a hydrocele; whereupon Mr. Liston pointed out the puncture-mark of an instrument upon the scrotum, intimating at the same time that he had carefully looked into the case. He had, in fact, a short time previously, tapped the tunica vaginalis, drawing off some coffee-coloured fluid; and it was in consequence of the examination then made that the extirpation of the part, supposed to be a diseased gland, was judged necessary. The preparation which is before you shows the tunica vaginalis enlarged and much thickened, and within it is contained, occupying, however, only a small part of the cavity, some fibrine, with a clot of blood. The testis is healthy, though apparently somewhat atrophied.—This too is so far from being a solitary case, that it has occurred to most surgeons of experience either to witness or to make a mistake of the kind. Sir Astley Cooper, treating of the diagnosis of some of the diseases of the same organ, speaks in these terms—"But still the distinction (between 'fungoid disease' of the testis and hydrocele), is sometimes difficult, and all candid persons will confess they have erred, and when they have believed it water have found it solid. Mr. Pott, Mr. Hunter, Mr. Cline, and many others have been thus deceived, and I am ready to confess that I have more than once been mistaken.—(" Observations on the Structure and diseases of the Testis," p. 128.) The mistakes spoken of in this extract appear to have consisted in a disease of the gland being taken for a hydrocele. The converse of this is illustrated in the case previously adverted to.

Seeing, then, that surgeons of the highest character, including one with whose great experience and unquestionable practical tact we had long and intimate acquaintance in this place, erred in the diagnosis of diseases of the testis, you will be prepared to believe that much caution ought to be exercised when it is sought to distinguish between some at least of those diseases. You will at the same time be prepared to learn, that the examination of a single case may involve, nay in many cases must involve, the consideration of several of the diseases to which the organ is liable, because, in order to arrive at a satisfactory conclusion as to what the morbid condition in a particular instance is, it is generally useful, often very necessary, to determine in the first place what it is not.

And now we return to the appreciation of the facts of the case before us. The translucency, the pyriform shape, the uniform yielding all over, or nearly all over, to pressure, which usually belong to hydrocele, are not present in it; while the great comparative weight of the mass, the adhesion of the tumour to the skin, the general hardness, accompanied with fluctuation at one point, which are present here, are so many positive signs of the tumour being a solid one, of the disease, therefore, being seated in the testis itself,—for the occurrence of any solid deposit in connexion with the tunica vaginalis, is so rare that it need not enter into our calculation. Taken individually, some of the signs enumerated might lead to an erroneous conclusion, but, in their combination they leave no room for doubt as to the seat of the disease.

In the next place it becomes necessary to decide upon the nature of the solid contents of the mass—to decide, especially, whether it is encephaloid matter, [soft cancer], or one of the "non-malignant" formations to which the testis is liable, for instance, the commonest form of these, "the simple chronic enlargement." Upon the solution of this question depends the plan of treatment to be pursued.

There is no certain sign by which encephaloid disease may be distinguished at an early stage of its growth. It is indeed true, that the body of the gland is the part first affected with this so named "malignant" deposit, and that it is only by extension from that part that the epididymis becomes involved. This fact is illustrated by the preparations and the drawings of cases before you in which I removed the glands from persons suffering under the disease alluded to, as well as from the bodies of others who died in consequence of it. It is likewise true, that in the "chronic enlargement," the epididymis is commonly the starting point for the morbid alteration. Inasmuch, however, as it is not invariably so, the help which the difference of the place of origin for the morbid deposit in the two cases is calculated to afford in the diagnosis is very limited, the more so because so little is the inconvenience caused by either disease at its outset, that the surgeon is usually not consulted till the time for taking advantage of it has passed. The time had long passed in Tucker's case.

Besides, when disease affects the gland itself, the fibrous investment of this being very dense, no sufficient evidence can be attained by the touch respecting the character of the deposit beneath it, while the tunic is in its natural state. But, as the disease advances, the membrane, under the influence of the pressure of the increasing tumour and of the morbid action set up in its neighbourhood, becomes altered so much that it no longer masks the character of the substance contained within. Moreover, other concurrent changes are taking place, which assist the diagnosis; and, before the mass has attained the size of either of the testes in the case under our observation, we find, in encephaloid disease, (only to refer to the most prominent characteristic signs,) that amid the general firm

(a) The observations here placed together as a single lecture were made partly when the patients were admitted at the hospital, and partly at the close of their stay in it.

resistance to pressure, some parts of the mass yield to the finger, and communicate a feeling of elasticity. Enlarged veins at the same time become manifest beneath the integument of the scrotum. The patient's health suffers the while; he has a general feeling of depression; his countenance becomes sallow; he loses flesh. Finally, the morbid deposit becomes manifest elsewhere—in the abdomen or thorax, but most frequently, according to my own observation, in connexion with the lymphatic glands before the lumbar vertebræ. To this it must be added, that the disease is confined to one of the testes, that its progress is usually rapid, and that it attains a large size.

In the disease of the gland known as the "chronic enlargement," the tumour attains a large size, it may be with considerable rapidity; it is generally unyielding to pressure, but fluctuation often occurs at a point, and a part of the glandular substance is liable to be protruded. Both the glands are in some instances affected, first one, and then the other. The general health is not impaired as a consequence of this disease; and other organs do not become affected by it.

Now, in our case the tumour has no feeling of elasticity; it is uniformly hard, except at one point where fluctuation is felt; the veins of the scrotum have not undergone any considerable augmentation of size; and both testes are much enlarged. While, therefore, the physical signs which characterize encephaloid disease are wanting, those which belong to the chronic enlargement are present. But, on the other hand, our patient has materially suffered in his health. There is, we have seen, sallowness of his face, with loss of flesh, and general depression. There is likewise evidence of disease in the abdomen; and, though no tumour is discernible in the lumbar region or elsewhere in that cavity, still the tenderness to pressure over the liver, or in its neighbourhood, affords grounds for a suspicion which must be cleared up. If the general ailment and abdominal symptoms be unconnected with the disease within the scrotum, they will, in all probability, yield to medical treatment, while, on the contrary, if they be the result of that disease, that is to say, an extension of it, no medicine that we know of, is likely to produce any material temporary amelioration, much less a permanent one. In order that you should estimate strictly the evidence the local symptoms afford in favour of the non-malignant character of the disease, I should here mention, that though very strong, it is not so complete, as to put aside all circumstances telling in the opposite direction. The facts of which it is made up, even when combined, do not afford conclusive evidence, such as, for example, the single fact of translucency does respecting the presence of a hydrocele. For, to take one of the signs relied on, viz., the enlargement of both the glands at the same time: I have adduced this as a proof, among others, of the disease in Tucker's case, not being "malignant." I have done so, because no example of disease which may be so designated has been seen by myself, or, so far I can learn, by the most experienced pathologists, to affect both testes at the same time. The fact is valuable in aid of others, but it must not be implicitly relied on in the diagnosis, inasmuch as there is nothing in the nature of things, nothing that I know of in the laws that regulate the formation of the morbid deposit in question, to render its co-existence in both the glands impossible. Observations of a similar kind might justly be made concerning other parts of the same evidence. We proceed, then, to the treatment of the case with the strong expectation, but not the certainty, that the abdominal symptoms will prove to be accidental: in other words, that they will prove to be independent of the disease within the scrotum.

The patient will, for a time, be kept in bed. This is no unimportant part of the management of his case. It is adopted, with these views, namely, to facilitate, by the position, the return of blood, to remove, at the same time, in the most effectual manner, the distress occasioned by the weight of so large a mass appended to the body by only the slender cord and a small fold of integument, and likewise to gain the advantage anticipated from a uniform warm temperature on the surface of the body. The use of mercurial medicine is decidedly indicated, and on these grounds, viz.:—1st. There is some biliary derangement; 2ndly. The medicine has a well ascertained effect in causing the removal of the deposit which constitutes the "chronic enlargement" of the testis; 3rdly. Although the skin-stain, noticed in the report as probably remaining from syphilitic disease, is not in itself,—that is to say, the person being in good health, and without any other indication of that disease, sufficient to require the administration of any medicine (I find it yield readily, in such circumstances, to an alkaline lotion,) still its association in this case, with general want of health, and with other disease, rendering the administration of mercury adviseable, is a reason the more for prescribing that medicine.

I now continue the abridged Report:—Hitherto no medicine has been taken by this patient with a view to control the disease. He was now ordered to keep in the horizontal position in his bed, or upon it; to have the testis supported properly; and to take blue pill and senna mixture as a purgative. For a few days afterwards he took this draught thrice a day:—Potas. carb. gr. x.; infusi gentianæ co. ℥i.; aquæ menth. pip. ℥ss. M. ft. haustus. The regular use of the following medicine was then begun:—Hydrarg. chlorid., gr. ij., in a pill night and morning, with potassæ iod., gr. iij; liquor. potassæ, ♏ x.; infusi cascarillæ, ℥i. in a draught, to be taken thrice a day.

This treatment being continued for a fortnight, the improvement was very decided. Now, the patient states, that he has not felt so well for the space of twelve months as he does at present. His health evidently is much improved; countenance better; appetite returned. But where fluctuation existed upon the scrotum, the skin has given way, and some curdy matter has escaped. In the breach of the skin, which is about the size of a sixpence, a dirty yellowish substance, of firm texture, is seen. The gums being tender, the dose of calomel was diminished to one grain, to be given once in the day.

After the lapse of another week the patient requested permission to leave the Hospital, in order to make some pressing business arrangements. At this period his condition is reported to be in all respects decidedly improved. His countenance, it is said, has lost the sallowness of hue, and the eyes have become free from the yellow tinge they had when he was admitted into the Hospital. There is, moreover, no uneasiness felt upon pressure being made over the abdomen, and the rigid state of the right rectus muscle has been altogether removed. At the same time, the left testis is clearly diminished in size. The medicines to be continued after the patient's return home. The scrotum to be well supported.

He showed himself subsequently from time to time at the Hospital. The opening in the skin over the right testis continued to enlarge, and the discharge increased. The left testis went on to decrease in size.

March 12.—Tucker is re-admitted, with the view of having the tumour on right side removed. He is now in very good health. The opening in the integuments over the right testis has attained the size of a crown piece. In the breach is seen the same kind of firm yellowish substance, and this does not project beyond the surface. As it was ascertained that he had been living intemperately for some time, he was kept in the Hospital several days, and took aperient medicine as a preparation for the operation.

In the operation, which was performed while the patient was insensible from the use of chloroform, a considerable extent of the skin was left upon the tumour. It was included with the ulcerated part between two elliptical incisions. Several small arteries required ligature.

During the two following days the patient, after having vomited some bilious matter, was troubled with pain at the epigastrium, and frequent eructations, from which he was relieved by warm stimulating applications to the abdomen, and the use of carbonate of soda, with tr. of cardamoms in mint water, taken at intervals. The disturbance, it may be added, was attributed by the patient himself to the chloroform. With little interruption, however, the case continued to advance steadily to its favourable termination. Being unwilling to remain longer absent from his occupations, our patient left the Hospital with a very small cicatrix marking the place of the operation. The left testis being still enlarged, he was directed to continue to attend as an out-patient.

June 16.—Tucker has not attended regularly since his dismissal from the wards of the hospital. He came, however, to-day, and his condition was found to be in every respect satisfactory. His health appeared quite established, vigorous in fact; and the left testis is still further diminished in size. The iodide of potassium, with liquor potassæ, to be continued as before, and at the same time a dose of blue pill, with extract of henbane, to be taken every night, instead of the calomel.

Observations.—The report states correctly that Tucker was re-admitted into the hospital for the removal of the right testis—if such the mass might still be called. His health having been much benefited, and the testis last affected and least involved in the disease having been diminished in size under the treatment adopted, all the apprehensions which the previous state of the patient's health was calculated to excite, had ceased. But why was the operation necessary? Could not the disease be removed by remedial means? The answer to such questions may be thus stated:—The "chronic enlargement" of the testes (of which disease we anticipate this case to be an example) consists in the deposit of plastic matter or lymph of yellow colour in the substance of the testis and in the epididymis, in consequence of a slow form of inflammation. At an early period, the secretion of this deposit is arrested, and the absorption of that already formed is best promoted by the use of medicine such as that administered in this case; but when the disease is far advanced, the natural structure of the gland is destroyed, and the accumulation of the adventitious substance is such that all hope of its removal by a natural process is at an end. To this condition the larger tumour in our patient seemed to have arrived, and this judgment respecting it was borne out by the circumstance that the medicine already used had produced no material effect upon it. On these grounds, I determined to extirpate the tumour of the right side, and then to return to the use of medicine with a view to restore the remaining gland to a healthy state. Here I may anticipate so far as to say, that unfortunately the patient, feeling himself in good health, and suffering no inconvenience from the local disease, has neglected to attend at the hospital; and it is not unlikely that this neglect will continue until it will be too late to check the progress of the disease in the remaining organ.

Upon the operation the only remark I think it needful to make at present has regard to the fact, that it was necessary to dissect the integument from the tumour, or the tumour from the integument, almost at every point. It sometimes happens that the separation between the two may be effected with little trouble, even in great part with the fingers. On the other hand, I have in some other instances seen the connexion between those parts equally close with that noticed in the operation upon our present patient. I would especially mention Mr. Liston's case alluded to in a former part of this lecture. It seems to me that the difference which occurs with respect to the point here adverted to, viz., the degree of connexion between the scrotum and the tumour, results from the greater or less proximity to the former of that excited action which attends the disease, and the common effect of which is to create an unnatural adhesion of parts. In Tucker's case the skin was adherent for some extent, and ulceration had taken place in it. In hydrocele, too, the part affected is but little removed from the skin; besides, in the example of this disease which has been adverted to, the tunica vaginalis was more than usually thickened. On the contrary, in many cases of diseased testis, whatever increased vascular action may be

present is well removed from the surface, and an unnatural connexion between the integument and the subjacent part, is on this account less likely to take place. The independence, moreover, of the vascular supply to the gland and to its investment, must not be forgotten in accounting for the various degrees of facility with which a tumour may be "turned out" from the scrotum in one case and another.

Examination of the Tumour.—There is no trace of the tunica vaginalis. The morbid mass, which is covered with a cellulo-fibrous membrane, consists for the most part of two portions of yellow, rather tough substance, obviously plastic matter or lymph. This substance is identical with that which forms the small yellow nodules deposited in the early stages of the chronic inflammation of the testis. Between the two masses into which this plastic matter is aggregated, there is interposed a quantity, varying in breadth from half an inch to an inch and a half, of whitish fibro-cellular tissue. Not a vestige of the glandular structure can be found. None of the seminal ducts beyond the vas deferens are discernible, even with the aid of a microscope. Doubtless the tubes have been altogether destroyed by the accumulation of the yellow substance, the deposit of which, in fact, constituted the disease.

[To be continued.]

LECTURES ON CLINICAL MEDICINE,

DELIVERED AT UNIVERSITY COLLEGE HOSPITAL.

By E. A. PARKES, M.D., Lond.:

Member of the Royal College of Physicians, Professor of Clinical Medicine in University College, and Physician to the Hospital.

LECTURE I.

GENTLEMEN,—There is no class of diseases whose study I should more strongly recommend to the student of Clinical Medicine, at the outset of his investigations, than the affections of the heart. For, independent of the numerous diseases which are proper to this organ, or have from it their starting point, there is perhaps no other organ which, by reason of its function and office, is so frequently implicated in the diseases of other parts. Every change in the quantity or quality of the blood makes itself felt here; every alteration in the dynamic condition of the other large organs produces here its peculiar sign; every moral or physical impression on the nervous system has a more or less direct and lasting influence upon the great organ of the circulation. So well is this known and appreciated, that we constantly refer to the action of the heart as a measurement, and, in some cases, an indication of local or general disease; and although, from the immense number of phenomena, the conditions represented by the numerous shades of difference in its action are even yet imperfectly understood, we are daily acquiring more knowledge of the phenomena, and more certainty as to the antecedents of which they are the symbols.

Our knowledge of special heart diseases, also, has wonderfully increased during the last few years. It has attained, indeed, in some points extreme exactitude; and, although there are still many cases in which the diagnosis is excessively difficult, in the majority we are enabled to arrive at certain results.

Without further preamble, however, let me enter on the consideration of the case I am about to bring before you. I shall make no apology for considering it somewhat minutely, as the discussion of a single case of this kind allows us sometimes to gain a comprehensive glance over many cardiac diseases.

On the 12th of July, on entering into my female ward, I found there a new patient, a young woman of the name of Mary Gartland, aged 24. My assistant told me it was a case of dropsy, and the first glance at the patient suggested the probable nature of the disease. The woman was sitting up in bed, propped up by pillows; she was more than sitting up, she was leaning forward; her arms were thrown in front and extended at length; she was breathing very rapidly and laboriously; every three or four minutes a violent paroxysm of hard cough came on, which was followed by scarcely any expectoration. The expression was anxious and fatigued; the lips were red, but darker than usual; the cheeks rather darkly flushed; the eyes prominent and watery. There was extreme anasarca of the lower extremities; the abdomen was distended, and the first tap upon it informed us that there was a large quantity of fluid in the peritoneum.

These few symptoms, collected at the first glance, led at once to a suspicion of disease in or about the heart, possibly with lung disease superadded, as common in such cases. The very aspect of the countenance, apart altogether from the peculiar attitude, the dyspnœa, and the cough, would have distinguished this case from one of renal dropsy. But of course our suspicion was quite provisional, and subject to the confirmation of the subsequent examination.

What, now, was the history of this case? The patient was a servant, of original strong conformation, and even on admission not at all emaciated; she had always lived well; was unmarried, and had had tolerable health, with the exception of occasional cough, till within the last three or four years. She then suffered for some time from cough and dyspnœa, and was eventually (in February, 1848) admitted into the Brompton Hospital; she nearly lost her cough while there, and left the hospital much improved; she then, after some period of rest, went again into service, and lived in a damp kitchen; after stopping here a short time, she fell ill of some complaint of which she gave no definite account, except that she was in bed for a week, felt very ill, and had "spasm of the stomach and chest," but did not cough or expectorate. Recovering partly from this she remained weak and ill, and suffered from palpitation.* Five weeks before admission she had an attack of violent vomiting, and this was succeeded by frequent attacks of vomiting for about a fortnight. About three weeks before admission she noticed that the feet and ankles, and the abdomen shortly afterwards, began to swell.

Her father died at sixty years of age, of, she says, phthisis; her mother at about the same age. Has several brothers and sisters, all in good health. Never had rheumatism; slight hæmoptysis shortly before admission.

Such was the previous history. Examination gave us the following particulars:—

I have already mentioned certain symptoms which led us to anticipate some disease of the heart, and probably of the lungs; what, then, were the states of these organs; and, first, of the heart:—

There appeared to be no undue prominence of the præcordial region. The apex of the heart was beating between the sixth and seventh ribs, nearly close to the sternum; the impulse was extremely irregular and unequal. Frequently the irregularity was so great, that nothing like regular order could be made out. At other times a feeble beat was rapidly followed by a powerful impulse, this again by a feeble beat, and then there was a long pause, after which the same sequences were repeated. There was no undulation or purring thrill; there was no pulsation in the neck, either arterial or venous. The præcordial dullness was considerable; its limits were at first not well-defined, on account of the difficulty of keeping the patient in the recumbent position; but it was made out that the right border was to the right of the sternum; the upper border was a little above the fourth rib; the outer border was undefined, on account of a large mamma, but was far to the left. There was then considerable increase of dullness, chiefly to the right and downwards. The heart, therefore, was manifestly larger than usual; for the extension to the right and downwards, and the non-extension upwards, independent of other symptoms subsequently ascertained, rendered the supposition of pericardial effusion very unlikely, and this is the only other common disease which gives rise to increased præcordial dullness. And, supposing that there was no displacement from great pleural effusion, which we afterwards proved there was not, it was plain that the enlargement was chiefly of the right ventricle, which thus had extended so much more to the right than usual.

But what light did auscultation throw on the size of the heart, and particularly on the condition of the orifices? At the base the sounds were generally so confused and intermingled, that for some time nothing could be made out; but, after two or three examinations, I satisfied myself that there was probably no bruit at this point; certainly none in the arteries of the neck. At the apex, on the first day of examination, there was a distinct softish systolic bruit accompanying the strongest impulse, and which was at its maximum, not at the apex but outside it; occasionally this murmur was lost, and we heard nothing but a series of confused sounds, which all appeared, however, to be systolic; to the right of the sternum the bruit was louder than to the immediate left of the sternum. There did not appear to be any second sound at all audible at the apex at the first or second examination. Afterwards we heard the second sound frequently; it was often reduplicate. Subsequent examinations did not disclose anything more; always there was an extreme irregularity, a systolic murmur, most marked at the apex of the left ventricle or at little outside it; reduplication of the second sound at the apex, and occasional absence of this sound.

The radial pulse was excessively irregular, rather hard, and very small—not locomotive. There was no increased dullness at the top of the sternum, or signs derived from the neck.

What, then, was the condition of this heart?

It was, as I have said, enlarged; *i. e.*, dilated and probably hypertrophied, as the impulse was often strong, and there was a good volume of sound, which was moderately muffled, as it frequently is in hypertrophy. We concluded that there was regurgitant mitral disease, inasmuch as there was a systolic murmur far to the left, and I concluded that there was tricuspid regurgitation, because, 1. There was also a murmur at the right apex, heard very loud sometimes to the right of the sternum, becoming fainter as we passed to the left, and then increasing again as the mamma was approached; and 2. Because there was manifest enlargement of the right ventricle and general dropsy, both of which conditions are frequently the consequence (the first, sometimes the cause) of tricuspid regurgitation. The absence of any signs derived from jugular pulsation, did not shake my opinion, inasmuch as it is necessary, before this sign of tricuspid regurgitation can occur to any marked extent, that the valves at the junction of the internal jugulars and subclavian veins shall be ruptured; then occurs the jugular pulsation from reflux, and sometimes refilling of the vein from below when the current is arrested above, or if the rupture be complete, absolute refilling at every systole; but in this case, as in many others in which considerable dilatation is combined with tricuspid regurgitant disease, the arrest of blood in the auricle, thence in the venous system generally, will cause general dropsy without absolute regurgitation through the large veins.

What was the condition of the aortic and pulmonary valves? We were enabled to determine nothing positive about them, on account of the irregularity of the heart's action; there was no decided murmur at the base, yet this, with the kind of heart we had before us, was negative evidence of no great value; for it is a fact which you will have frequent opportunities of confirming, that to develope a murmur at the aortic orifice, either obstructive or regurgitant, you must have a good current of blood. In this case the flow of blood was very feeble, on account of the general stagnation of the circulation, and also because, as we shall presently notice, the lungs were in a congested state, and allowed comparatively little blood to pass through them. Therefore the condition of the arterial orifices remained doubtful, but I was on the whole inclined to believe them tolerably sound.

What was the condition of the pericardium?—a question we ought always to ask in these cardiac affections. We had no symptoms of any kind directly derived from the pericardium. There appeared to be no increase of percussion dulness, attributable to pericardiac effusion; there was no

friction now, or at any subsequent time. There were two symptoms present which have been referred to pericardiac adhesions, viz., an irregular action, and a diminution merging into a loss of the second sound. But these signs, although they correspond occasionally with pericardiac adhesion, are by no means confined to this state, or are even necessary to it. In hearts whose cavities are all dilated, irregularity is almost a constant symptom, and, in this condition, the jogging, tumbling, tumultuous action described by some writers, as significant of adhesions, also frequently exist. The loss of the second sound, too, does not always occur in pericardiac adhesions, occurs in other cases, and is, in fact, merely coincident with, and not dependent on, adhesions. Besides, in this case, the second sound was occasionally heard at the apex, and generally at the base. One consideration made me decide against pericardial disease, and this was the fact, that the patient said she had never had rheumatism, and that she certainly did not labour under Bright's disease. Now, as I mentioned to you in a former Lecture, these are the most important of the six diseases, in the course of which pericarditis may come on; (viz., acute rheumatism, Bright's disease, phlebitis, pleurisy, poisoning of the blood in certain so-called zymotic diseases, and scurvy,) and as these, with probably all the other causes of pericarditis, were now, and had been always, absent in this case, I decided against pericardial disease.

What, now, was the condition of the muscular substance? Was the hypertrophy accompanied by fat deposition, either external or internal, to the sarcolemma? We had no evidence as to this point, except in the fact, that the heart contracted occasionally very forcibly, which did not look like a fatty heart, and that the patient was younger than most subjects of fatty heart appear to be.

Thus, to sum up. We supposed we had a heart enlarged and hypertrophied in all its cavities,—in both ventricles certainly,—and, according to the usual course of such affections, both auricles being dilated and thickened to some extent; the mitral and tricuspid valves being incompetent; the aortic valves possibly diseased, the condition of which, however, could not be accurately made out; the pericardium being healthy.

Now, let me so far anticipate the history as to state, that the patient died a month after admission into Hospital. What was the state of the heart after death?

In the first place, the heart lay under the sternum, the right and left cartilages; it was nearly uncovered by lung, and much enlarged, weighing 14 oz. Instead of the pericardium being healthy, it was everywhere adherent by old, firm cellular tissue, so dense as to be separated with difficulty from the heart. All the cavities were of great size; the walls of all were thickened; the auricles were more enlarged and hypertrophied in proportion than the ventricles, but the ventricles were also thickened: thus, at the base, the walls of the right ventricle were half an inch; at the apex, a quarter of an inch thick; the walls of the left ventricle were seven-eighths of an inch thick at the base, half an inch at the apex; the muscular substance appeared coarse and dark coloured, there was a little mottling on some of the columnæ carneæ in the right ventricle. In all the cavities there were enormous clots. The state of the endocardium and valves was as follows: —In the left auricle, the endocardium was opaque, of a dead white colour, and much thickened; also, there was a dense, firm, white, fibrous-looking layer beneath it, from which it could be raised very readily; this was most conspicuous in the auricle, but passed into the ventricle, being lost in its lower half; the mitral orifice was contracted; it admitted the fore finger, but scarcely allowed the tips of two fingers to enter; on looking at it from above, the ring seemed corrugated; stretched out, the circumference was three inches; the flaps were extremely thickened, particularly along the free borders, which were rounded; the thickening arose from a firm fibrous layer between the folds of opaque endocardium, the cordæ tendineæ were shortened and thickened; it was not clear that the flaps were incompetent to close the opening, although they may have been so. The aortic valves did not support a column of water; the orifice was contracted, and, when stretched out, measured only 2½ inches in circumference; the flaps were thick, rigid, and did not collapse; they were contracted in all their dimensions, and drawn towards each other by dense fibrous bands seated beneath the opaque and thickened endocardium; the free margins were rounded; the greatest thickening of each flap was around the corpus arautii, and it diminished thence towards either cornu; the flap away from the corpus cut hard under the knife, and was from 1½ to 2 lines in thickness. The thickening was evidently dependent on deposition between the folds of the endocardium. There was a point or two of atheroma in the aorta, but the vessel did not appear otherwise changed. On the right side, the appearances were different; the auricular endocardium was smooth and of normal colour and consistence. The tricuspid opening was small; it admitted only the points of two fingers, and measured, when stretched, only three inches; the flaps of the valves were beaded, somewhat thickened; the chordæ tendineæ were thickened, and considerably retracted, so that the flaps did certainly not rise readily into place. The pulmonary valves were healthy. The vena cava superior was large; the valves at the commencement of the innominate veins were healthy and competent.

Therefore, correcting our diagnosis by this inspection, the condition of this woman's heart was, perfect old adhesion of the pericardium; hypertrophy and dilatation of all the cavities, most marked in the auricles; thickening of the auricular, and, in a less degree, of the ventricular endocardium on the left side, and deposition of contractile exudation matter below it; obstructive, perhaps regurgitant mitral disease; obstructive and regurgitant aortic, the last probably slight; obstructive and regurgitant disease of the tricuspid.

Let me briefly consider the symptoms in connexion with these lesions. The dullness, on percussion, was attributable to enlargement; the irregular action, &c., were, of course, attributable to the dilatation, hypertrophy, and probably also, in part, to pericardiac adhesion; the tricuspid regurgitation gave its systolic bruit at the right apex; but the systolic bruit at the left apex was not, apparently, attributable to mitral regurgitation. Can a systolic bruit arise from mere thickening, or roughness, of the mitral valve, while it still remains competent? You may remember we observed, in a case of phthisis, this really did seem to occur; we had a systolic bruit at the apex with a competent but thickened mitral valve. Two cases of the same kind are recorded by a very excellent writer, to whom I shall have to refer in my next Lecture, viz., Dr. Blakiston. Therefore the possibility of such a thing being almost certain, our present case not improbably belonged to the same class. I am uncertain whether the obstructive mitral and tricuspid disease indicated themselves; we noticed, as I have already said, that occasionally the second sound was what we called reduplicated at the apex; now, after the *post-mortem* examination, it struck me that the supposed reduplication might actually have been a diastolic murmur at the apex, for you are aware that, in obstructive mitral, a murmur often exists which follows the second sound, or sometimes obscures it.(a) The aortic obstruction and regurgitation were marked by no sign, or rather, we noticed none. The state of the pulse might have arisen from mitral disease, from aortic obstruction, or from a weak and dilated heart.

So much for the heart in this case. Now, what was the state of the lungs on admission?

The extreme dyspnœa passing into orthopnœa, and the violent paroxysmal cough, coupled with the known condition of the heart, made us, of course, suspect congestion of the lungs, and, perhaps, something more. All over the chest, anteriorly and posteriorly, except at the extreme bases, there were dry and moist bronchitic rhonchi; cooing, whistling, submucous, and subcrepitant. At both bases there was slight dulness on percussion, disappearing when the patient lay on her face; diminution of vocal fremitus, and a distant and feeble respiration mixed with cooing rhonchi. These signs indicated fluid in the pleuræ, and that this was simple hydrothorax, and not the product of pleuritis, was evident from all the circumstances of the case. The fluid changed its position very readily, so much so that it might have been concluded that the pleuræ were almost free from adhesions. When the patient was found in a position she often assumed, viz., on her hands and knees in bed, with pillows underneath the body to support its weight, the percussion note at the extreme bases became quite clear. The expectoration, which was moderate in amount, was frothy, and, as usual in these cases, sometimes more or less opaque, sometimes greenish, and generally copiously streaked with blood.

Was there any other pulmonary disease besides this congestion, secondary to the heart disease, and this hydrothorax? We could make out nothing. But in this case, as in all others in which there are great bronchitic râles, and particularly if there be pleuritic effusion or hydrothorax, I am in the habit of hesitating for a long time before I decide, from the mere negation of symptoms, that there is no other pulmonary disease. We left, then, the state of the lungs, as respected other diseases, uncertain. No material change took place in the pulmonary symptoms till death, except some increase in the hydrothorax. After death, the lungs were in the following state:—There were several pints of clear serum in each pleural cavity. The left lung was adherent at the apex, by old adhesions, and posteriorly by recent soft gelatinous-looking threads; the pleural surface was elsewhere smooth; the mucous membrane of the bronchial tubes was much injected; the tubes contained a good deal of frothy mucus. This was more conspicuous in the lower than upper lobes; the pulmonary substance was dark red and firm; in the lower lobe unusually so, sinking in water; cutting rather dense, but smooth; not in the least granular; not softened, and evidently only much compressed. The right lung was adherent at the apex only, and presented exactly the same characters as the other lung, only in the lower lobe there seemed to be certainly a little diffused hæmorrhage into the substance of the lung. There was not the least trace of tubercle in either lung; but there was some calcareous transformation of the bronchial glands.

Such was the state of the lungs, which was evidently only secondary to the heart affection, and presented, indeed, a good type of the condition which follows moderate mechanical impediment to the passage of blood through the left cavities, when, at the same time, compressing forces, such as hydrothorax, oppose the entrance of air.

What, now, was the condition of the abdominal organs?

I have already said, that there was a good deal of fluid in the peritonæum; now, in cases of this kind, this condition may depend simply on hepatic congestion, consequent on the obstruction at the heart, or on structural hepatic disease, arising out of such congestion, or on actual independent and original disease of the liver, consequent on its own peculiar causes, and being more or less aggravated by the cardiac affection with which it happens to be combined.

We learned the following particulars into the state of the liver:—The liver dulness could be detected some little way below the mammæ, but was not perfect till the seventh rib; from this to a line drawn on a level with the umbilicus, there was perfect dulness; from the umbilicus a line, impinging at an open angle on the left false ribs, about 3½ inches from the median line, marked the course of the left lobe; the liver was a little tender; the edge could not be felt. It was evident, therefore, that the liver was much enlarged. Its upper margin was also a little lower than usual, a circumstance which was probably not attributable to the small

(a) In one case of decided diastolic murmur at the apex, derived unequivocally from mitral obstruction, which I have seen, the murmur followed the second sound, but was decidedly separated by an interval, although a short one, from the first sound. It did not occupy the whole interval of rest.

quantity of fluid effused in the right pleura, but, as is the case in Phthisis, to the constant and violent cough.

But what was the condition of the hepatic substance? There were two things to guide us; 1st. The liver was more enlarged than it usually is in mere congestion; 2nd. The ascites had succeeded the anasarca more rapidly than it usually does in uncomplicated cardiac affection. For, in heart disease producing dropsy, the extremities first usually swell, then, gradually, ascites come on, and, perhaps, serous collections in the pleura or pericardium. But, when the ascites is coincident with, or precedes, or follows, at an extremely short interval, the anasarca, there is always ground for suspicion that the liver has itself been damaged, and, consequently, has suffered from the advancing heart disease, sooner than would have been the case had it been in a more healthy condition. In the case before us we did not know at what date the ascites had come on, whether even it might not have preceded the anasarca; but we were certain, that if it followed this, as the patient believed, it must have been at a very short interval. But now, as to the nature of this liver disease. There was more enlargement than in granular liver. Malignant disease, lardaceous liver, hepatic suppuration, or cystic growths, were out of the question. The liver was, therefore, probably in the condition of nutmeg liver, or less, probably of uncomplicated cirrhosis, or uncomplicated fatty deposition. Let me remark, in explanation of these terms, that, although the chronic diseases of the liver are still obscure, though, as Rokitansky observes, the "granular liver" is a very enigmatical affection; yet, we are prepared to say, that, under the terms cirrhosis, nutmeg, and hob-nail liver, &c., very different things have been described. Tracing the morbid changes back to their elementary forms, we may, I believe, safely indicate, at least, three special starting points. In one case, there is deposition of contractile exudation matter in the liver; this is true fibrinous granular liver. In another, the elementary change commences in a kind of stasis and dilatation of the minute lobular biliary ramifications, and is followed by changes in the cells. This is true cirrhosis, producing granulation, and is apt to combine itself with fibrinous granular liver. In a third form there is fatty deposition, which, with congestion, or more exquisitely still, by combining itself with true cirrhosis, may produce nutmeg liver. To the complex condition produced by such combination, fibrinous granulation may be added. These three elementary conditions are independent of each other, or may be primary or secondary to each other, and combined with each other, and with congestion, in all conceivable ways. To return from this digression: After death this was the condition of the liver. It was non-adherent; its peritoneal surface was smooth. It was much enlarged, weighing 69 ounces; the antero-posterior diameter measured 8 inches; the transverse, 10; the depth at the thickest part, 2½. The left lobe was rounded and enlarged, but not much prolonged. The surface, as seen through the serous coat, was mottled with white spots; the serous coat, when detached, brought away some granules of hepatic tissue with it. The surface then presented, scattered over the whole liver, several round bodies, the largest of which were the size of small peas; they projected from the surface, were of an uniform yellowish colour, cut soft under the knife, and looked to the naked eye like fat. These bodies appeared, in many cases, to be inserted among, and to displace the hepatic tissue. At the posterior part of the right lobe, the colour became nearly uniformly yellowish, and the lobules appeared to be entirely occupied by a similar deposit to that of the rounded masses before referred to. The outline of such lobules was distinctly marked out, by a tolerably well-defined, apparently portal, injection. The rest of the liver presented a greater or less approach to the same appearance; a yellowish and fatty-looking substance being deposited in the lobules, and perhaps around them. On section the same change was found to have gone on in the interior of the organ, but more in some parts than others. There was, also, in the interior, extreme hepatic congestion of the first and second degree, forming long and broad patches, and large central islands, in some cases merging apparently into true punctiform and maculiform hæmorrhages. In some parts, nothing could be seen but the hæmorrhagic spots, and the soft, yellowish substance before referred to. Although the soft substance looked fatty, it gave no greasy appearance to the knife. The coats of the gall bladder were a little thickened; the reticular membrane injected; there was about one ounce of thickish, stringy bile in it.

On microscopic examination, the scrapings of a piece of liver, moderately diseased, gave, 1st, liver cells crowded with oil globules, the cells, if anything, larger than usual; 2nd, large globules of oil scattered about the field. The scrapings of a piece of liver, greatly diseased, gave liver cells quite *crammed* with oil globules; in some places, the cell walls were so thin as to be hardly seen, and the nuclei appeared to have gone, or at any rate were quite concealed.

Therefore, in this case, there was evidently fat deposition, with both portal and hepatic congestion, in part dependent on such deposition, in part on the condition of the heart. Probably the fatty disease was, in this case, attributable to chronic hepatic congestion, and slow, fatty transformation; and I think this variety of nutmeg liver is, perhaps, the more frequent form of liver change, consequent on obstructive heart disease. But we seldom find it in so pure a state as this; usually it is combined with more or less original disease of the liver, and deposition of other matters in its texture.

So much for the liver. The spleen gave us no signs during life. After death, we found it small, (4½ ounces,) firm, and apparently unchanged.

What was the condition of the kidneys? On first admission, the urine was scanty, seldom reaching to more than fourteen to twenty ounces, and deposited red amorphous lithates in great abundance. It subsequently underwent, for two or three days, a remarkable augmentation in quantity, to which I shall have presently to refer, and afterwards, again became moderately scanty, *i. e.*, from twenty to thirty ounces, acid, with large sediments of red amorphous lithates. It never contained a trace of albumen,—a circumstance to which I particularly request your attention. I, therefore, concluded that the kidneys were healthy, but this was a mistake. After death, they were found to be fatty in a high degree. The right kidney weighed seven ounces; the capsule separated readily from a smooth pale surface, on which was very little polygonal or stellate venous injection. On section, the cortical substance was broad and pale, the malpighian bodies injected; the pyramids appeared normal. The left kidney weighed six ounces; the capsule separated very easily, as in the former case. At one point was a depression with radii. The depression seemed to be formed by old exudation matter, and was connected with a vessel of some sort, which ran up from between two of the pyramids to unite itself, apparently, with the effused substance. Otherwise, this kidney presented the same appearances as the other one; the cortical substance being pale, broad, with the malpighian bodies injected. On microscopic examination, we found that this pallor, and broadening of the cortical substance, were due to extensive fat infiltration; the epithelial cells were crowded with minute oil globules, and fat was also profusely distributed in the field of the microscope, so much so that I thought it could not have been derived entirely from rupture of the cells, but must have existed around them, in, or, possibly, between the tubes.

Now, let me request your attention to this fact: here we had fatty kidneys,—indeed, marked specimens of the kind,—without a trace of albumen in the urine during the five weeks this patient remained in Hospital. And the albumen was not temporarily absent, as it may be sometimes in Bright's disease, the urine evidently presented characters differing from those it exhibits in advanced Bright's disease. We may feel certain, then, even from this single case, that a considerable degree of fat-infiltration is not necessarily attended with the presence of albumen in the urine. It would be unwise to deduce any further consequences from such a conclusion; but we may put the questions to ourselves, whether this non-appearance of albumen was dependent on any unusual condition of the circulation in this case, (although one would suppose there must have been renal congestion,) or whether the blood was in any state unfavourable to the passage of albumen by the kidneys, or whether—as I cannot but suspect, from this and some other cases—true fat-infiltration is really unattended by albumen in the urine, which, when coincident with it, is not produced by it, but by some other condition remaining undetected, and which is the real antecedent. But this is not a point for our present discussion.

Let us now take up the general history of this case after its entrance into Hospital. Our first object was to attempt to relieve the cardiac and pulmonary organs as rapidly as possible; and this was to be done, first, by acting upon the kidneys and intestinal mucous membrane by diuretics and purgatives; and secondly, by the administration of such sedatives and expectorants as might be likely to relieve the congested pulmonary circulation. Accordingly, I ordered half-ounce doses of bitartrate of potash, and small doses of camphor, digitalis, and ipecacuanha. In a short time, a certain amount of improvement was perceptible; the hydrothorax somewhat diminished, and the patient could lie down; but the improvement was not great, and after five or six days I ordered diuretics. At first we began with the acetate of potash and juniper, but this seemed to have no effect, and I then cautiously added digitalis. The digitalis, gradually augmented, and administered, at the same time, as pill and infusion, was carried to a considerable point, without any marked effect. After she had taken it in large doses two or three days, however, it seemed to act almost suddenly on the kidneys. One day, nine days after admission, we found the urine, which in the preceding 24 hours had been 10 oz. only, augmented to 90 oz., of a light colour, transparent, and of a specific gravity of 1007. The next day the quantity was 74 oz., and I began to hope that we should have one of those lucky cases in which diuretics act like a charm. But, on the evening of that day, such extreme languor, nausea, and tendency to syncope, came on, that I was compelled to omit the digitalis for some time, and, though I then resumed it in smaller doses, it seemed to have no effect, and I finally left it off altogether. On the day following the evening of syncope and prostration, the quantity of urine began to decrease, and on the next day had returned to its old standard, or nearly so, of from 15 to 32 ounces in 24 hours, acid, of a specific gravity from 1018 to 1025, and loaded with lithates, which assumed occasionally, towards the end of the case, a marked pink tint. We continued the purgatives and expectorants, without any perceptible effect. Generally eight or ten loose stools were procured, but the anasarca never seemed to decrease, although the cough and dyspnœa were certainly relieved. We also acupunctured the legs; the fluid, which ran out in large quantity, was alkaline, and, with heat and nitric acid, threw down a considerable quantity of albumen. And here let me remark the interesting fact, that, while this fluid effused, as a result of obstruction, into the subcutaneous areolar tissue, did contain albumen, (a) the urine was so remarkably free from it; and yet, as I shall have occasion to mention in my next Lecture, from cardiac obstruction merely, albumen will often appear in the urine. A month after admission, the symptoms were more grave; the collections of fluid had increased; erysipelatous inflammation set in round some of the punctures, which had been made incautiously below the knee; this increased, and passed into sloughing; then on the 13th of August she was seized with an attack of violent watery purging, and died on the following day. On examination, the only thing worthy of note, in addition to the circumstances I have mentioned, wa

(a) Which it does not always do. I have made analyses of these fluids, and found them sometimes to contain albumen, sometimes no albumen, only salts, and a little incoagulable organic matter.

firmly adherent granular effusion of lymph upon the mucous membrane of the lower part of the jejunum, and here and there upon the ilium, to some little extent. Peyer's patches, in the ilium, and the whole of the large intestines, were free from this effusion. There was no head affection throughout the illness, and the encephalic organs were healthy.

Such were the facts of this case. Now for the inferences. The point of difficulty is to know how this heart disease originated. The previous history of the case is so imperfect that we cannot determine this. Had we been able to satisfy ourselves that the patient had suffered from rheumatic fever, or even had had rheumatic pains, the interpretation of the case would be easy; and as it is, in spite of the assertions of the patient to the contrary, I cannot help suspecting that she must have suffered from rheumatism. Possibly this may have been one of those cases in which the joint-affection is moderate, the cardiac disease extreme. Admitting this, we should read this case in the following way:—At some indefinite period before admission, perhaps during rheumatism, pericarditis and endocarditis probably occurred together; the former affected the whole pericardial surface, and rapidly led on to universal adhesions; the latter attacked chiefly the endocardium of the left side, and implicated not only this membrane, but the tissue below it. Then gradually, by the contraction of the sub-endocardial deposits, slight co-arctation occurred at the mitral orifice, and slight rigidity of the aortic flaps. While this contraction was going on, the heart was also experiencing the effects which general and firm adhesions of the pericardium induce; its action was becoming irregular, and at times palpitating; then at a certain date the contraction of the mitral orifice had gone on to such an extent that the auricle, in order to overcome the obstacle, began to dilate, and became hypertrophied. This speedily produced reflux through the pulmonary veins, and congestion of the lungs. Then probably followed the attack, for which she was eventually admitted into the Hospital for Consumption. Relieved by the rest and judicious treatment she here experienced, she left the Hospital; but, as I learnt from the friends, never seemed well, and they, in fact, always considered she was breaking up. The contraction of the mitral being followed by contraction of the aortic orifice, the left ventricle was now called upon to overcome this obstacle, and became hypertrophied in consequence; not to any great extent, however, because its own contracted mitral orifice cut off, in part, its supply of blood. Had it not been so, it would have become greatly hypertrophied, and probably have broken down, by the force of the current, those rigid aortic valves. The continued, though slight, congestion of the lungs of course impeded the flow of blood from the right ventricle; this, then, became hypertrophied. The tricuspid orifice also being thickened and contracted by the local endocarditis which had occurred here, produced an obstacle to the flow of blood, and led on to hypertrophy and dilatation of the right auricle and general venous stagnation. Then it also gave way before the force of the ventricle, or the shortening of its chordæ tendineæ destroyed its competence. At length, under these various influences, the effects of dilatation of the cavities, obstruction at the mitral orifice, moderate tricuspid regurgitation, and tricuspid contraction, with auricular hypertrophy, showed themselves in general dropsy and increased pulmonary congestion.

Before this, however, we may well suppose that the liver and kidneys had commenced to undergo their fatty degeneration or deposition, under the influences of the cardiac affection to which they had been submitted, and which seem frequently to produce similar effects, although the exact steps of the process are not known.

After the entrance into Hospital, the course of the affection requires no illustration.

THE CHOLERA AT TORPOINT, DEVON

By A. McCLURE, Esq., R.N.,
Member of the Royal College of Surgeons.

The cholera having broken out at Torpoint, the Board of Guardians of the St. German's Union procured the assistance of two medical gentlemen, to co-operate with Mr. Chubb, the only resident practitioner in the neighbourhood; they were, however, soon obliged to leave. Application was now made to Captain Nicolas, Royal Naval Hospital at Plymouth, who, with the concurrence of Dr. Rae, the Inspector, granted the services of two Naval Medical Officers. Mr. Bowden and I were selected for the duty. Mr. Bowden being almost immediately ordered to rejoin the Hospital, I was deprived of his valuable assistance.

The town of Torpoint, distant about a mile from Devonport, on the opposite side of the river Tamar, is apparently healthy. The population amounts to about 1600. It is chiefly composed of sailors, labourers belonging to the Dockyard, &c.; a number of families generally reside in the same house, and occupy, according to circumstances, one, two, or more rooms, which, for the most part, are devoid of any means of ventilation; the sewerage is very bad; but the greatest evil with which the inhabitants have to contend, is the inefficient supply of water; at times, in the summer months, it is with difficulty that they are enabled to procure enough for culinary purposes, end even this is of a deleterious and unwholesome quality.

I came to Torpoint on the 1st of September. The place was in a very sickly state. Mr. Chubb, whose attention to the poor people suffering from the disease had been most praiseworthy, was quite exhausted from overwork, and unable to attend to his duties. Cholera prevailed to a considerable extent, and diarrhœa was to be met with in almost every second house; the inhabitants, also, seemed greatly depressed and panic-stricken. Here, as in other towns I have visited, the disease was confined to the lower classes, and to the more wretched, filthy, and worst-ventilated districts; in fact, wherever a foul drain or an offensive privy existed, either cholera or diarrhœa was sure to be found close by. Such a state of things rendered it absolutely necessary to adopt prompt and energetic measures in order to better the condition of the people, and to arrest, if possible, the spread of the epidemic.

I have always been impressed with the advantages that would result from a system of house-to-house visitation, properly organised, in localities where cholera prevails, and had determined to give it a fair and impartial trial, should another opportunity ever offer; so, after a short consultation with Mr. Chubb on the subject, we decided upon introducing it without delay.

While carrying out this most salutary measure, I endeavoured, at the same time, to improve the sanitary state of the town, and add to the domestic comforts of the inhabitants; for this purpose, houses of refuge were secured, to which a number of persons were removed from the overcrowded and infected districts; a more nourishing and generous diet was gratuitously supplied to such of the people as required but could not procure it; the dwellings in those localities where the disease had made its appearance were whitewashed, thoroughly cleansed, and plentifully besprinkled with the chloride of zinc; all nuisances, the removal of which was not considered to be injurious, were taken away; but there were a few dung-heaps of such magnitude, that I considered their being disturbed might be prejudicial to the health of those residing in the immediate vicinity, from setting free a quantity of noxious gases. These I had covered over with a thick coat of quick-lime. I originally intended flushing the streets, lanes, and especially the sewers, with water, by means of a fire-engine, but, in consequence of the great scarcity of water, I was obliged to abandon the idea. Such a proceeding would, I am certain, have been attended with great benefit.

I have already mentioned that the sewerage is very bad, and there being no water to carry off the accumulations of filth, a most offensive odour was frequently to be met with. In such cases I had recourse to Sir William Burnett's solution of the chloride of zinc, which at once did away with the smell, and rendered the place quite pure. This invaluable preparation has been extensively used in the town and neighbourhood of Torpoint since my arrival, and its virtues highly appreciated, even by the lower classes; for twelve months I have had daily opportunities of testing its efficacy, and am fully convinced, that, as a deodorant and disinfectant, it stands unrivalled.

It having been represented to Captain Nicolas, that the supply of water was inefficient and unwholesome, he at once, with his usual generosity, proposed to remedy this evil by sending as much as would be required for the use of the town, from the Royal William Victualling Yard, which he has continued to do regularly for upwards of three weeks; this is one of the greatest blessings that could have been conferred on the poor people, and I have no doubt it has materially aided in mitigated the severity of the disease.

When I first commenced my professional visits, I found the diarrhœa to be of a most obstinate character, and a number of cases, in spite of treatment, lapsed into confirmed cholera. This state of things continued for a few days after I came here, and rather discouraged me at the outset. Upon making careful inquiries, however, I discovered that the diarrhœa with which I had then to contend had been going on for two or three days, and in some instances much longer, without any application having been made for medical aid; but, latterly, a most remarkable and salutary change in this respect has been brought about by the house-to-house visitations, through which diarrhœa is now discovered on its first appearance, and brought under medical treatment at an early period, a few doses of some ordinary astringent medicine generally relieving the symptoms. Thus, out of 253 cases of diarrhœa which I have had under my care since I came here, I have only had six in which cholera has supervened, when I have had an opportunity of treating the malady at its first commencement.

On referring to my notes, I find, that on the 2nd instant, when I entered upon my duties, I discovered 10 cases of cholera, and 35 of diarrhœa; in the great majority of instances, the diarrhœa was of considerable standing; from that time up to the present, I have had under my care 29 additional cases of cholera, and 218 of diarrhœa, making, in all, 39 of the former, and 253 of the latter; of the 29 cases of cholera, 16 occurred in persons who had been suffering from severe and long-neglected diarrhœa, and for which they had become patients of mine on the first or second day after my arrival, and before the house-to-house visitation had been properly established; 3 were persons who, although I had been in the habit of visiting at their houses daily, were fool-hardy enough to disregard the premonitory symptoms, and to allow the diarrhœa to run on for upwards of a week ere they applied for relief. These, I may add, are the only individuals I have yet met with who have not been glad to avail themselves of the advantages which the system of house-to-house visitation is calculated to confer. Two of them have already paid the penalty of their negligence with their lives, and of the recovery of the third I have no hope: the remaining six cases are those previously mentioned as having lapsed into cholera from diarrhœa, notwithstanding the adoption of early and energetic treatment; and even of this number, but one person died, which affords additional evidence of favourable results arising from the timely administration of proper remedies.

The following Table exhibits the number of cases of cholera, and the deaths that have taken place weekly, from the 12th of August, the day on which

it made its appearance at Torpoint, until the 16th September, when the last case occurred:—

	Cases of cholera.	Deaths
From 12th Aug. till 19th Aug.	11	6
" 19th " 26th "	15	6
" 26th " 2nd Sept.	32	17
" 2nd Sept. till 9th "	22	5
" 9th " 16th "	7	3
Total	87	37

In addition to those above mentioned, 12 deaths are registered from the Union Workhouse; but the number of persons attacked does not seem to have been reported; and, as they all occurred before my arrival, I cannot give the proportion of the mortality, but believe it was very great.

The foregoing statement cannot fail to show, that the measures adopted for the purpose of arresting the progress of the pestilence with which this town has been visited have been remarkably successful. We find the disease steadily progressing, from the date of its first appearance, until the 2nd instant, when the house-to-house visitation was suggested; and, as soon as this and other sanitary precautions decided on were brought into operation, the health of the inhabitants rapidly improved.

Since the outbreak of the present epidemic in Plymouth in the beginning of July, I have had opportunities of observing upwards of 300 cases of genuine cholera, and I have never yet met with a single instance in which the disease has not been preceded by diarrhœa of greater or less duration. Surely, then, if such be generally the case, and if we can, in the majority of instances, prevent cholera by arresting the progress of the diarrhœa in its early stages, no means ought to be neglected to enable us to seek out the premonitory symptoms, and thus successfully combat such a malignant and fatal disease; and that the house-to-house visitation secures this most desirable object, no one with any experience can deny.

And here I would remark, that it is by no means prudent to abandon the system as soon as the epidemic shows symptoms of abatement; in many places we find a recurrence of the disease after a short cessation; and when the inhabitants were beginning to congratulate themselves that it had taken its departure from among them, it has suddenly reappeared with increased and fearful malignancy, numerous examples of which have come under my own observation in this neighbourhood. To guard against such a calamity, (although there has not been a single fresh case of cholera in the town for nearly a fortnight,) I still continue to keep, up to the present hour, the daily visits to the houses of the inhabitants; and there is good reason to believe that this has been a wise precaution, as I have, on several occasions, noticed an increased tendency to diarrhœa, which would, in all probability, have lapsed into cholera, had it not been promptly attended to.

A circumstance now recurs to my mind, which, although foreign to the object of this report, may, perhaps, be worth bringing under notice. When the cholera was raging, some few weeks ago, among the corps of Royal Marines belonging to the Plymouth division, I was often astonished at the numbers brought into the Naval Hospital in a state of collapse on the first outbreak of the epidemic. The patients were sometimes so much exhausted, on admission, as to be unable to give any account of their illness, or even state when they had been attacked. Upon inquiring, however, it invariably appeared that they had been suffering from diarrhœa for several days before they thought it necessary to acquaint the Surgeon with the state of their health, the great majority of them labouring under a false impression that the diarrhœa was salutary; and to such an extent did this prevail, that some instances have come under my notice of persons whose bowels had acted upwards of twenty times in the space of a couple of hours, ere they sought advice. Since that time, I have often thought that it would be a prudent measure to adopt, (when any tendency to diarrhœa manifests itself,) on board ships of war, or in regimental barracks, to place a sentry in charge of the water-closet, who would be instructed to report to one of the Medical Officers any individual found to visit that place oftener than twice or thrice within a stated period. I have no doubt that were this precaution carried out, it would be the means of preserving the health and saving the lives of many of Her Majesty's servants.

It is acknowledged by all, that cleanliness and ventilation are most powerful adjuvants in successfully contending with any epidemic; in cholera they are found to be pre eminently advantageous. That the house-to house visitation ensures these desirable objects being brought into practice by the lower orders, is sufficiently evident from the frequent opportunities afforded medical men, and others so employed, of coming into contact with the poor, and observing the state of their dwellings; every visitor should impress upon those under his care the absolute necessity of living in clean rooms, and of breathing a pure atmosphere, and personally ascertain, in his daily visits, that his orders and suggestions in this respect are carried out, that the windows are opened, and that all filth and refuse are removed from the houses, and by so doing he will soon discover a most wonderful and gratifying change in the health of the people who reside in his district. I am particular in mentioning these injunctions, in consequence of the difficulty I have myself met with in conquering the slovenly habits of the people. I have frequently observed, among the lower classes of society, that there is no more desire on their part to live in well-ventilated apartments, than there is for a decent regard to cleanliness; but a little perseverance and determination will speedily overcome these prejudices.

Many persons are opposed to the system of house-to-house visitation, on the ground that it keeps up a panic without answering the purpose intended. This my own experience proves to be without the least foundation. During my frequent intercourse with the poor since I came here, I have invariably found them, with the three exceptions already alluded to, quite willing to come forward and relate their ailments; and when the object of my repeated visits to their houses was explained to them, most grateful did they seem for the trouble and interest taken in their welfare.

The expense incurred by carrying out the system is also adduced as an argument against its adoption. I am certain that those who thus reason have never taken into consideration the future cost that will of necessity be incurred by the parish, in maintaining those who may have been left destitute. During the three weeks' ending the 2nd instant, before the house to-house visitation was established here, there were 29 deaths; from that date up to the present time, there have only been 8 deaths. In both instances, the Poor-law Guardians must provide for the widows and orphans of those who died without leaving a provision for their families. Let those who are conversant with workhouse economy and parochial expenses, declare in which case the greater amount of expense will be eventually entailed upon the ratepayers. Why, the money paid for funerals alone, during the former period, would, in my opinion, nearly suffice to meet any extra expense incurred; besides, if, on the principle that prevention is better than cure, the system advocated can in any way tend to subvert the predisposition to, and, consequently, in many cases, the occurrence of that dreadful malady, is it not repugnant to the feelings of every right-minded individual, that the small additional cost objected to should be laid in the same balance with, and outweigh the preservation of human life?

In carrying out the sanitary measure suggested by me in this town, most valuable assistance has been rendered by the Rev. Richard Dunning and Captain Wriford, of the Royal Navy. The resident Medical Practitioner being often absent in attending to a large country practice, I found it quite impossible of myself to look after the health of all the inhabitants. The above gentlemen kindly volunteered to visit those localities to which it was out of my power to go, from want of time, and, whenever they met with any case of a suspicious nature, they had the person at once sent off to the Dispensary, or, if unable to leave the house, I was informed of the circumstance, that I might be in attendance as soon as possible.

Having given a good deal of my time and attention to the study of the present epidemic, perhaps a few words as to the treatment I have followed, may not be uninteresting to you. In recent diarrhœa I find that a dose or two of chalk mixture, or some of the compound chalk powder, (the latter being better adapted for children,) for the most part relieve the symptoms; when irritability of the stomach and sickness supervene, I generally administer a mustard and salt emetic, and, if the patient complain of pain or cramps in the abdomen, I cause either a sinapism or turpentine epithem to be applied over the stomach and bowels. Sometimes I have found, in this stage of the disease, stimulants—when cautiously administered—to be attended with benefit, more especially in young persons; I usually prescribe a tablespoonful of brandy, with a little water, or some of the compound spirit of ammonia, tincture of cardamoms, and camphor mixture, combined, every half hour; when rice-water purging comes on, I invariably have immediate recourse to calomel, which I give in five or ten grain doses, every hour; but, in the exhibition of this medicine, I do not confine myself to any fixed rule, nor do I servilely follow this, that, or the other plan, so frequently insisted on, as absolutely requisite to ensure success, being guided entirely by the character and urgency of the symptoms, and the constitution of the patient. As my chief object now is to affect the system, I usually cause a drachm or two of the strong mercurial ointment to be rubbed into the axillæ. If the purging be very violent and frequent, I give directions for the administration of some astringent enema, which has sometimes quieted the bowels; if at this stage of the disease the patient can be brought under the influence of mercury, there is every reasonable hope for his recovery, should he even pass into a state of collapse; but, when once collapse has set in, without the medicine having taken effect upon the system, then, in my opinion, the less we do the better, as I have never yet been enabled to ascribe the recovery of a single individual from this state to the administration of any remedies commenced after it has come on; and I am fully convinced that nature can, and will do more at this period, (if left to herself and not meddled with,) than all the highly praised and numerous specifics that are being daily brought under public notice.

Although I have given a very short sketch of the treatment which I have found, from experience, to be most successful, I am firmly convinced, that, with our present imperfect knowledge of the pathology of this disease, it is not on medicine alone that dependence is to be placed, if we would diminish the amount of mortality caused by the epidemic. Perhaps, however, it is right that every feasible remedy should get a fair trial; but, hitherto, I have seen almost every one employed that has been suggested, and, although I have read of the wonderful cures effected by them even in the last stage of the disease, I have invariably found them all to be signal failures, and I am convinced, that if the premonitory symptoms be not attended to, and the disease grappled with at the onset, very little is to be hoped for from these sources.

And now that the fearful pestilence with which our country is at present visited, has been the means of directing the attention of the authorities, and the public generally, to the privations, as regards domestic comforts, &c., to which the lower orders of the people have been subjected, let us hope that something will be done, without loss of time, to ameliorate their condition; as to their dwellings, the plentiful supply of good and wholesome water, and the drainage,—let these and other judicious sanitary measures be at once brought into operation, and it will be found that cholera, typhus, and all other such preventible diseases, will be of much less frequent occurrence; and that, when they do come among us, they will be deprived of much of their present virulence.

I regret that I am unable, from want of time, to enter more minutely into these matters just now; perhaps, at some future period I may take an oppor-

tunity of doing so, as many circumstances have lately come under my observation, in connexion with the epidemic now raging around us, that I am anxious to bring before the Profession, but which, for the present, must be omitted.

Torpoint, Devon, Nov. 1849.

[The exertions made by the excellent Author of this communication, and the results which followed them, are good examples, both of the steps which Medical men should adopt in similar emergencies, and the admirable effects which prompt and efficient Medical assistance produce. It does not appear too much to say, that Mr. McClure positively arrested cholera in Torpoint, and that the salvation of the lives of many persons are to be attributed entirely to him. This is as it should be. Even this terrible pestilence of cholera is not beyond the barriers which human intellect can impose upon it, if this intellect is wisely and judiciously exerted.—ED. *Medical Times.*]

HOSPITAL REPORTS.

ST. BARTHOLOMEW'S HOSPITAL.

INJURY TO THE KNEE-JOINT FROM THE EXPLOSION OF GUNPOWDER.

ACUTE INFLAMMATION, CAUSING TOTAL DISORGANISATION OF THE JOINT; AMPUTATION ON THE THIRTY-THIRD DAY AFTER THE INJURY.

William Hogley, a sallow-looking youth, about sixteen years old, was brought into Kenton ward on the 28th October, 1849, with a small lacerated wound of the skin, about two inches above the patella, occasioned by the explosion of a little cannon charged only with gunpowder and wadding. In the opinion of those who first examined it, the wound was considered superficial, and the knee-joint uninjured, so that this subsequently very interesting case, did not, in the first instance, attract particular attention. After a few days, the wound began to suppurate freely, and it became necessary to enlarge it, in order to give a more ready outlet to matter which was burrowing along the thigh. In this trifling operation, hæmorrhage, from a divided artery, took place to so great an extent, that the pulse and the countenance of the patient were manifestly affected by it. We would draw attention to this circumstance, the more because this considerable loss of blood did not ward off the very acute inflammation of the joint which subsequently took place.

The case proceeded without creating any anxiety till the twelfth day, when there suddenly arose unequivocal symptoms of active inflammation of the knee-joint, accompanied with severe pain, fever, and a quick pulse. In the hope of subduing this inflammation, the limb was placed upon a splint, leeches were applied to the joint, and two grains of calomel, with two grains of antimony and one-fourth of a grain of opium, were given every eight hours. This treatment, however, was of no avail. Not only the joint, but the parts above and below it, became considerably swollen; and the least pressure, or the slightest motion of it, occasioned severe pain. The wound looked flabby, glassy, and without any secretion; but a thin, purulent fluid escaped from it when pressure was made upon the ham, and a probe could be introduced deeply in the direction of the knee. These circumstances, taken in connexion with the constantly accelerated pulse, and the haggard expression of the countenance, made it nearly certain that the joint communicated with the wound, and that its interior was in a state of suppuration.

The question was soon settled. On the 28th day, distinct fluctuation being perceptible on the inner side of the knee, an opening was made, which gave exit to a considerable quantity of pus, and through which a probe was passed straight into the joint. The evacuation of this matter was certainly productive of temporary relief, and the pulse decreased in frequency for a day or two afterwards. But the train of symptoms speedily resumed their former character. In spite of every effort to support the constitution by a suitable treatment, and in spite of the fact, that the patient was able to take his food, and, with the aid of opium, enjoyed, to a certain extent, comfortable rest at night, he nevertheless grew, from day to day, gradually worse. Therefore, after a consultation with his colleagues, in which it was the opinion of the majority, that the removal of the limb would afford the best chance of life, Mr. Stanley, who had charge of the case, performed the amputation by the circular operation, on the 33rd day after the receipt of the injury.

The examination of the joint fully justified the propriety of amputation. There was pus in the interior, the synovial membrane was thickened, soft, and pulpy, the cartilages were extensively ulcerated, the bones bare in several situations, the fibro-cartilages disorganized, and the ligaments softened. The original wound communicated freely with the joint in two places; one immediately above the patella, the other at the back of the joint, close to the tendon of the popliteus muscle, this being a situation in which the synovial membrane is the least protected by fibrous structures, and therefore, in almost all instances, more prone to give way.

Up to the time of our present report, that is, on the tenth day after the operation, we are happy to state, that the patient is progressing in all respects most favourably.

We would suggest one or two considerations concerning the class of cases of which the foregoing is a good example.

First, then, supposing an apparently superficial wound to have occurred in the neighbourhood of a joint, it would appear to be by no means so easy to determine, in the first instance, whether the joint be opened or not. One ought, therefore, to treat such a case with all possible care, just as though the joint itself were implicated in the mischief, and this the more especially, if the joint in danger happen to be a large one. Secondly, assuming the joint to be opened, untoward symptoms may not come on till the expiration of many days. In the case before us, inflammation did not arise till the 12th day. Many other instances might be adduced in illustration, but it may suffice to mention rather a remarkable one, which happened last summer in the Hospital. A cart-wheel passed over a boy's leg, and made a lacerated wound into the knee-joint on the inner side of the patella. Three weeks had elapsed, and the wound had nearly healed, when most acute inflammation suddenly attacked the joint. Such was the severity of the local and general symptoms, that there were very soon good grounds for believing that suppuration of the joint had taken place, and accordingly a free opening was made into it. The opinion that the joint had suppurated proved to be correct; but the opening and the evacuation of the matter did not in the least degree relieve the constitutional symptoms, which would unquestionably have rapidly proved fatal to the patient, had not amputation of the limb been performed as a last resource. In this case, also, the joint was entirely disorganised.

In penetrating wounds of the knee-joint, which have produced suppuration in its interior, it is considered by some hospital surgeons to be a proper measure to make a free opening into the joint, and to let out the pus, and this whether or not the joint be distended by it, but we have never seen a leg saved by such a proceeding. May we not safely say, that it is the opinion of most of the leading surgeons in this country and on the Continent, that no reasonable benefit can, even at best, be anticipated from such opening, unless the joint be suffering from excessive distension, and that, after all, these cases require amputation at last. The following instance is adduced, in order to exemplify the opinion held on this subject by the late distinguished surgeon Professor Rüst, of Berlin.

"A young man struck himself on the inner side of the patella with the point of a hatchet, which penetrated into the knee-joint. For nine days afterwards he followed his ordinary work without any pain or inconvenience; but, on the twelfth day, violent inflammation arose in the joint, and ran its course with such rapidity, that suppuration was considered to have taken place in it when the patient was brought under the notice of Professor Rüst. Convinced by long experience of the fatal results of similar cases, the Professor recommended, to the no small surprise of the young surgeons present, that the limb should be immediately amputated; but the patient refused to submit to the operation, and died in about thirty days after the receipt of the injury."

REMOVAL OF AN EXOSTOSIS FROM THE LAST PHALANX OF THE GREAT TOE.

This operation has lately been performed by Mr. Lawrence. The patient, a young man from the country, had an exostosis growing from the upper surface of the last phalanx of the great toe, and projecting beneath the nail. He ascribed the origin of the growth to the toe being trodden upon by the foot of a horse. The tumour had existed for about twelve months, and during the last six had caused so much pain as to prevent the wearing of a boot. Heretofore, it was the practice to remove the whole of the ungual phalanx in cases of this disease; but of late years the mode of operating adopted at St. Bartholomew's Hospital is as follows:—A flap is made from the soft parts beneath the under surface of the phalanx; an incision is then made across the matrix of the nail down to the bone, and the end of the phalanx, with the tumour attached, is removed with the cutting forceps. The flap of skin is afterwards raised over the divided end of the phalanx, and confined by one or two sutures. By this proceeding the long flexor tendon of the toe is not injured; neither is the root of the nail removed; so that, after a new nail has formed, the toe looks very slightly altered, except that it is a little shortened.

UNUSUAL SIZE AND COURSE OF THE SUPERFICIAL PERINÆAL ARTERY.

In a male subject lately dissected, the superficial perinæal artery on the left side was nearly as large as the trunk of the internal pudic, and proceeded across the perinæum, lower down than usual towards the mesial line, so that it lay directly in the way of the incision in lithotomy. But besides this, the artery of the bulb in the same subject, also crossed the perinæum nearer to the anus than usual; consequently, had lithotomy been performed in this instance, there must have been divided two large arteries, either of which might have occasioned fatal hæmorrhage.

CUT THROAT.—INSTANTANEOUS DEATH FROM SUFFOCATION, PRODUCED BY BLOOD IN THE TRACHEA.

A patient in Dr. Hue's ward, suffering from dyspepsia, committed suicide by cutting his throat. Death was almost instantaneous. On making the *post-mortem* examination it was discovered that the trachea and the larger bronchi were blocked up by blood, and that blood had been sucked into the lungs, the right especially. The incision had divided the alæ of the thyroid cartilage, and both the superior thyroid vessels. The carotid arteries and internal jugular veins were not injured.

UNIVERSITY COLLEGE HOSPITAL.

Several operations were performed on Thursday, 29th November, of which the following are the most important:—

LITHOTOMY.

Henry Tappin, aged four years, a fine, healthy-looking boy, admitted under Mr. Quain, on account of stone in the bladder.

A small calculus, which had become impacted in the urethra, was dexterously removed by Mr. Hurman about twelve months ago. But symptoms of stone in the bladder are, and have for some time been evident. Urine spirts from the little patient as he walks about. He suffers much pain at times; has frequent desire to make water; rests upon his hands and knees to do so, and wets his bed at night; prepuce is elongated; he is constantly pulling at it.

When he was admitted into the Hospital a small stone was pretty clearly felt with a sound; but, upon repeated trials afterwards, there was only a sensation as if some calcareous matter were rubbed

with the instrument. At length the "click" of the sound against the stone being distinctly heard, the day for the operation was fixed.

Nov. 29.—The child being brought into the operating theatre, while under the influence of chloroform administered in the ward, and the stone being again clearly felt with a sound, Mr. Quain at once proceeded to operate, and extracted a small nodulated calculus.

Dec. 1.—The child was heard singing on the morning after operation; and he is now in all respects doing well. The tube was removed in thirty hours. The urine is quite clear, and it flows freely. The position in which the staff was held in this case is worthy of notice. In the ordinary mode of using the side-grooved director, the instrument is retained in one unvarying position—the handle directed vertically; but, in the present instance, Mr. Quain had the handle at first held towards the pubes, away, therefore, from the operator more than usual; and, when the scalpel entered the groove of the staff, the handle of this was then inclined forwards to the usual position, *i.e.*, nearer to the operator.

The effect of this deviation from the usual course, which was fully explained in the Clinical Lecture to-day, (Dec. 1,) may, in few words, be stated as follows:—The first position of the director is intended to bring the grooved part of that instrument nearer to the surface of the perinæum, and so to facilitate "the first difficulty" of the operation, viz., the introduction of the scalpel into the groove of the staff; while the change in the position of the director, when the scalpel has reached the groove, raises this and the cutting instrument away from the rectum, and from the lower part of the bladder during the section of the prostate gland. The object seemed to be fully attained in the operation.

STRICTURE OF URETHRA—FISTULA IN PERINÆO—OPERATION.

James Graby, aged 54, admitted September 17, under Mr. Quain. Stricture of urethra, traceable to repeated attacks of gonorrhœa during the last eight years. Retention of urine twice during that period. In 1818 an abscess formed in the perinæum, after an attempt to pass an instrument along the urethra.

This patient is a spare, thin man, with an anxious, care-worn countenance. He is anxious to have any means used that may be thought necessary to relieve him of his sufferings.

At junction of scrotum and perinæum, and in the median line, is a fistulous opening, with the tissues much thickened and indurated around. The stream of urine is exceedingly small, and there is frequent desire to pass it. At each act a few drops escape through the fistula. The introduction of bougies was almost invariably followed by rigors; and the stricture was not improved by their use, for, though on more than one occasion dilated to some extent, it again quickly returned to the original very narrow state. Under these circumstances, an operation was determined on.

November 29.—Chloroform having been administered, a full sized wax bougie was passed down to the stricture, and marked with reference to the meatus. The smallest lithotomy-staff being found too large to pass through the narrowed part of the urethra, a very slender straight director, with the extremity slightly bent, was introduced along the whole length of the canal without any difficulty. [This instrument was constructed with reference to the present case.] The patient being then put in the position for lithotomy, incisions were made into the urethra through the fistula and the surrounding indurated substance. The depth was very considerable, the tissue cutting like cartilage.

After the urethra had been laid open for about half an inch, the director was withdrawn, and a well-sized catheter passed down; but this instrument was arrested beyond the incision in the canal, the whole of the stricture not having been cut through. The director being now re-introduced, the incision previously made in the urethra was continued backwards. The catheter then slipped in easily.

Mr. Quain stated, that if the fistula and surrounding tumour had been at the side of the perinæum, the operation would have been a more easy one, for in that case the incisions would have been made in the middle line, without regard to the tumour. He added, that he had to perform the operation without a measure of the length of the stricture. The position of the anterior end of this was determined with a bougie, and that of its posterior might have been sufficiently ascertained beforehand, if the fistula admitted a probe to pass into the urethra. But as it was impossible to make a small director penetrate any distance along the fistula, he had to divide the stricture by two separate incisions.

Dec. 1.—Catheter removed, having been retained since the operation without any inconvenience.

AMPUTATION OF THE THIGH FOR LONG-STANDING DISEASE.

William Russell, aged 56, admitted Nov. 17, for extensive chronic ulcer of right leg, with disease of tibia and fibula, originating in an injury received in 1834. The wound had remained unhealed since that time. He came into the hospital for the express purpose of having the limb off.

It was deemed advisable to amputate immediately above the knee joint, for there was reason to doubt the soundness of the upper end of the tibia. Bilateral flaps were formed.

In this instance, as in others, Mr. Quain cut the flaps short, dividing when they were held back, the deeper muscles by a circular incision, as in the common circular amputation, thereby adding to the extent of the soft parts required to cover the bone, and dividing the larger vessels transversely. The flaps extended to the side of the knee-joint, and the bone was sawed as near its lower end as was compatible with the formation of flaps without reaching the flesh of the leg.

Examination of Leg.—On removing the muscular substance from tibia and fibula, the anterior surface of the former presents a large oval roughened elevation. Its prominence above the general surface of the bone is considerable. It is tuberculated, and distinctly denuded of periosteum in some places, especially along its inner and most prominent margin. On removal of the periosteum, the bone is seen to be considerably injected, especially the more roughened parts; throughout this membrane is thickened. The fibula is enlarged, and at one part has entirely lost all appearance of surfaces and margins. The soft tissues between the tibia and fibula are extremely dense; and the bones are united one to the other below at several points by osseous matter. On section, the compact tissue is seen to have so encroached upon the medullary canal as nearly to obliterate it.

KING'S COLLEGE HOSPITAL.

On Saturday last, Mr. Fergusson had several operations of interest. Amongst the cases was that of a young child, who had two nævi on the scalp, which were of that description involving the skin, and chiefly composed of the ramification of the small arteries. Each of these tumours was treated in a different manner. The first, Mr. Fergusson strangulated, by means of a knot of strong ligature passed completely around the base of the nævus; the other tumour was operated on by the needles, which were passed through the base of it, at right angles to one another, and the ligature was then twisted firmly around them, and the morbid mass was thus effectually circumscribed.

After this operation, a young girl was brought into the theatre, who was suffering from necrosis of the ulna. The disease had existed for some time, and there were indications of a large portion of dead bone, lying either loose or in process of separation. The arm was much inflamed, and greatly swollen; and there was a large fistulous opening in the centre, through which a probe could detect diseased bone. Mr. Fergusson, therefore, deeming the present a proper time for interference, made a free incision through the diseased parts, and, on carefully examining the bone, found a considerable portion dead; and by means of a strong pair of forceps, he removed a portion of the necrosed ulna, at least four inches in length, and apparently involving the entire thickness of the bone.

On Saturday last we recorded a case, in which Mr. Fergusson performed the operation of cutting a stricture through the perinæum. An operation of a somewhat similar character was performed upon a man this day. The patient had suffered, in the most literal sense of the word, from a bad stricture of the urethra for about twelve years, and he had been under the care of Mr. Fergusson at a previous period. The structure was, at that time, exceedingly irritable and undilatable, and, although a moderate sized catheter could be passed through it, so little relief was obtained, and there was so great a tendency in the urethra to contract again, that it was determined to cut him; and he was actually brought into the theatre for the purpose of being operated on, at the same time that an operation of a similar character was being performed on another patient; but, Sir Philip Crampton being present, recommended Mr. Fergusson to abstain from the proceeding; and, instead, to put the patient under the influence of chloroform, introduce as large a sized instrument as possible, and keep it in the bladder. In deference to so high an authority, Mr. Fergusson pursued this course of treatment; but, after remaining in the Hospital some time, the patient left much in the same state. In the course of six months he was again admitted; and Mr. Fergusson proposed the division of the stricture, to which proceeding the patient willingly consented to submit. The operation was done in the following manner:—A No. 6 staff, with a groove in its centre, was passed through the stricture; the knife was then carried through the centre of the perinæum down upon the groove, along which it was slid against the stricture, until the whole was divided; an elastic catheter was then introduced, and then retained.

It will be noticed, that this operation is similar to one recommended by Professor Syme—only there is this difference: the Edinburgh Professor divides the stricture from behind forwards, whilst Mr. Fergusson cuts from the urethra towards the bladder. The great principle is the same—namely, *the introduction of a director through the stricture*, upon which the division is made. Of course, this operation was comparatively simple; far different from that performed last Saturday, where no instrument could be passed, and where the structures of the perinæum were extensively diseased; and Mr. Fergusson, in some sound and practical remarks, forcibly contrasted the two proceedings, and pointed out the cases in which each operation was applicable.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

PROHIBITION OF NEWSPAPERS IN THE PARIS HOSPITALS.

The political condition of this distracted country necessarily influences nearly all its Institutions; but it will hardly be believed that political rancour pursues the sick within the precincts of an hospital just as, in the dark ages, it followed them even beyond the tomb. Yet such is the case. The convalescent patient in this, as probably in every other civilized country, has hitherto been permitted to read the political journals. The privilege of sale was generally confined to the hospital porter, and the patients, at small expense, contrived to pass many a weary hour with pleasure, at least, though, perhaps, unprofitably. This trifling consolation has been suddenly removed from them by order of the authorities. Henceforward, that is to say, until better times come, the doors of every hospital in Paris are to remain closed against every species of political publication. Neither the servility of the *Constitutionnel*, nor the hypocrisy of the *Patrie*, has availed them against the pitiless proscription. All are confounded under the same decree. It is difficult to account for this harsh and cruel mea-

sure. The democratic journals, being the cheapest; are those generally read by the hospital patients, but the character of the publication can hardly explain the severity of the order. It would be more simple and efficacious to forbid at once the people from learning to read. By-the-bye, the same measure has been recently applied to the army also. The private soldiers are strictly prohibited from reading any newspaper whatever, either in their barracks, in places of public resort, or in private houses. If the "schoolmaster be abroad," he is not assuredly in the guise of a politician. But these things excite little attention here, for few have faith in the Imperial pastime of placing chains on the human mind. Besides, in our present case, every one looks more or less to himself, and no one to "*la chose publique*," hence, the poor patients must "devour their solitude," as best they can.

HOMŒOPATHY IN PARIS.

Great noise is being made about the introduction of homœopathy into one of our public hospitals. This procedure has given great offence, and, it is said, the affair will become matter of Government investigation. It has already been submitted to a Committee of Hospital Physicians. Practically speaking, a great majority of French medical men are little better than Homœopathists; that is to say, they leave the cure of most diseases almost entirely to nature. They avoid, however, the quackery of pretending to administer medicines, when, in reality, they give nothing active. As Dr. Johnson said to Mrs. Bozzi, "they do not flatter themselves that they are making tea, when they are only making water."

From the followers of Hannemahn we learn that which it is impossible to learn from the practice of other physicians—the natural course of every disease, and the power of nature in the cure of disorders.

But such knowledge is incompatible with the English system of general practice. Where the medical man is paid for his drugs, not for his science, the former must necessarily take precedence of the latter.

The abolition of this unscientific and fallacious system must be the keystone of medical reform in England. Without such a change, medicine can never be elevated from a trade to a science, and, so long as a radical vice of this magnitude remains uncorrected, it seems a mere waste of time and power to occupy oneself, as the Hanover-square reformers are now doing, with the subordinate *enfantillage* of collegiate fellowships. I wish they could see how little is thought of a Court here now.

HEAT FROM ELECTRICITY.

M. Despretz is continuing his interesting experiments with the electric pile, some of the results obtained from which he communicated at the last meeting of the Academy of Sciences. Having succeeded in bringing together 600 elements of Bunsen, he submitted to the action of this formidable battery the most refractory metals, and has succeeded in melting or volatilizing them all—platinum, palladium, borium, silicium, titanium, and tungstenium. The hardness of this latter metal is remarkable; nothing but the diamond will act on it, and it may probably be employed for the cutting of glass and turning jewels. It is also possible that the solidity of this metal may be increased by the addition of steel, without any diminution of its hardness; and, if such be the case, then we may have a substance capable of replacing the precious stones in all instruments requiring great precision. It also appears that the battery may be employed to melt the parings of platinum. M. Despretz succeeded in melting eight ounces in a few minutes, and he would have melted a much larger quantity had his charcoal crucibles been sufficiently capacious.

PAINTER'S COLIC.

The diseases to which all persons connected with the manufacture of lead for painting are subject, have long fixed the attention of medical men, and of the authorities charged with the care of public health. It is well known, that, so far back as 1783, M. Guyton-Morveau proposed to substitute the oxyde of zinc for white lead, and thus avoid the accidents occasioned by this latter substance; but all attempts to apply the zinc practically failed, until the recent discoveries of M. Leclaire removed the difficulties.

It would appear, however, that the improvements of modern science enables the manufacture of white lead to be conducted without the slight injury to the health of the workmen. Within a period of ten years, that is, from 1838 to 1847, no less than 3142 patients, labouring under the poisonous effects of lead, have been admitted into the hospitals of Paris; and of these 1898 were furnished from two manufactories alone. Now, Messrs. Lefebre and Co., of Lille, who manufacture 3000 tons of white lead annually, have demonstrated that proper hygienic precautions enable their workmen, 150 in number, to escape the poisonous effects of the metal. Not a single workman had suffered from lead colic for the space of twelve months, during which the new methods were employed. These have been examined by a Committee of the Institut, (MM. Pelouze, Kayer, and Combes,) who have verified the truth of the statement made by the Lille manufacturers, and who conclude, that the evil effects of lead may be completely avoided by the following precautions:—

1°. Mechanical processes should be substituted for manual labour, so as to relieve the workman from the necessity of handling the metal.

2°. Water should be employed during the separation of the chips from the residue of the lead, their pulverization and sifting.

3°. Instead of potting the white lead with water, it should be moulded in prisms or oblong masses.

4°. The white lead should be ground up with oil in the manufactory, and by proper machinery.

5°. All the apparatus employed in pounding, sifting, &c., the white lead, should be used in chambers isolated from the workshops. The issue of any deleterious matters through the necessary orifices in these chambers might be prevented by directing currents of air through the openings, and making the connecting machinery revolve in rings of an elastic material.

6°. Finally, the above measures will be completed by an active ventilation of the workshops, and by the ordinary hygienic precautions familiar to all the workmen.

The Committee are of opinion that the manufacture of white lead will cease to have any injurious effect on the workmen, as soon as it shall be conducted on the above principles.

CITRATE OF MAGNESIA.

This salt may be substituted, in many cases, for the sulphate of magnesia with advantage, for it possesses all the purgative qualities of the latter without its bitter and disagreeable taste. It may be made in the following simple manner:—Take of dry citric acid 14 parts, carbonate of magnesia 10 parts, mix them together and conserve them in well stopped bottles. To prepare, say 30 scruples of the citrate, you take 23½ scruples of this powder and dissolve them in water, and so in proportion, according to the quantity desired.

TREATMENT OF RABIES.

At a recent meeting of the Academy of Sciences, M. Rochet d'Hericourt read a short note on a root and plant which he brought from the north of Abyssinia, and which he believes capable of curing rabies. The powder is prepared from the root by simply removing the bark from the latter, and then drying it; ten to twelve grains, are administered in a small spoonful of honey or milk. In about an hour and a-half, when the patient has been freely purged and vomited by the remedy, he is made to take a large quantity of whey. The patient is soon reduced to a considerable degree of debility by the evacuations; to arrest which, some roasted fowl, very strongly seasoned with pepper, is given to him.

M. Rochet witnessed himself the effects of this powder; and relates the following example of its efficacy.

"Soon after my arrival at Devratabor, a mad dog having bitten three other dogs and a soldier, the King sent for me and said, 'You shall now see the value of the remedy of which I spoke to you.' He then ordered the four dogs to be confined separately. On the following day a spoonful of the remedy was administered to the dog which had bitten the others. It produced, at once, its emetico-cathartic effects, and the animal recovered.

"Eight days afterwards the remedy was given to another of the dogs, in whom the symptoms of rabies were beginning to appear. This animal likewise recovered. In the third dog the symptoms did not appear until the twelfth day, and he also was cured. The fourth animal died, with all the symptoms of rabies, on the forty-second day after the bite. No remedy had been administered to this animal.

"The soldier was not submitted to treatment until the tenth day. He then complained of a sense of weight in the head, which was hot; he was very much depressed, though subject to excesses of passion, spoke little, and had a stupid look. When a cup of hydromel was offered to him, he refused to drink, and a copious saliva escaped from his mouth. A dose of the powder was now given in a spoonful of milk; the usual evacuations ensued, and the man recovered."

A Committee of Hospital Physicians, assisted by M. Pelouze and M. Richard, has been appointed to investigate this interesting subject.

SCOTLAND.

[From our Edinburgh Correspondent.]

For a week or two past several circumstances have tended to keep alive among our brethren in this quarter the discussion of the great principles on which the improvement of medicine depends—a discussion which began for the present with the publication of Dr. Walshe's Introductory Lecture in the *Medical Times*. The lectures delivered at the opening of the Edinburgh Medical Courses often run in this channel, and probably Dr. Walshe's example increased the natural bent on such occasions towards this line of discourse. But the appearance of an article in the *North British Review* for November, entitled "Locke and Sydenham," understood to be from the pen of Dr. John Brown of this city, has had a still more material influence over our speculations on the proper foundations of medical improvement. The author, lamenting that the principles of medicine did not obtain the benefit of Locke's undivided attention, and pointing to Sydenham as exhibiting a model of the kind of mind fitted for their advancement, pronounces mere science to be an insufficient direction in the actual practice of medicine. The article itself is very able as a scientific, as well as a literary production; and, what will best convey an idea of the scope of the principal views maintained in it is the following passage, condensed, as it would seem, by Bacon from Plato:—"Particulars are infinite, and the higher generalities give no sufficient direction in medicine; but the pith of all sciences, that which makes the artsman differ from the inexpert is *in the middle propositions*, which in every particular knowledge, are taken from tradition and experience." We feel much indebted to Dr. Brown for placing this remarkable passage before the Medical Profession, at a time when the higher generalities so often threaten to swallow up all that is valuable in the practical precepts which have accumulated in the past ages of Medicine. When scientific medicine is extolled, to the disparagement of the practical precepts of such lights of the Profession as Sydenham, we should take care to learn the exact sense in which that expression is used. Nor should it be forgotten, at such a moment, that Medicine properly and essentially consists in procuring a change from a state of disease to a state of health. When, then, an enthusiast speaks of the necessity of rendering Medicine purely rational or scientific, our first question to him should be, whether he expects soon to be able to deduce the appropriate treatment from the mere discovery, or supposed discovery, of the nature of the disease. How few cases could be enumerated at present, in which the nature of the disease declares at once, with any measure of exactness, the most approved method

of treatment. Let us try an example. Thus, as soon as it becomes known that heartburn and spasmodic pain of the stomach are dependent chiefly on acid acrimony, science supplies the appropriate remedy in an alkaline agent. And, if we assume for a moment that the nature of the acrimony, which most commonly excites heartburn and spasmodic pain of the stomach, was not known till chemistry proved it to be an acid; and that alkaline remedies were not used against these affections till chemistry had taught the reciprocal relations of acid and alkali, then we have here an exact instance of scientific practice, though but a case of palliation at the utmost. How few cases are parallel to this in simplicity! And let us not fail to remark how many thousands of the human race suffered from heartburn or from spasmodic pain of the stomach before science was sufficiently advanced to point out the remedy from the nature of the affection, and how rude might be the state of knowledge among men at the time when accidental experience could discover that a little chalk, or a bruised shell, or an infusion of the ashes of the hearth, afforded relief to these disorders of the stomach.

But, suppose that science could already lay down a general rule in many diseases; it is well known that most diseases cannot be treated with perfect success without taking into account the peculiarities which each case derives from the constitution of the individual in whom it occurs. Here science almost wholly fails; and there is room for the exercise of what Dr. Thomas Young, as quoted by Dr. Brown, terms "an incommunicable faculty of judgment, and a sagacity which may be called transcendental, as extending beyond the simple combination of all that can be taught by precept." In short, though diseases are not quite analagous to the passions, yet there is a sufficient parallelism between them to afford some illustration of what we have to contend with in the practice of Medicine. Anger, hatred, jealousy, are abnormal states somewhat parallel to diseases, and there are general rules applicable to the soothing of such passions; yet, with how little success will these rules be employed except by those who have had opportunities of becoming acquainted with what is pre-eminently called human nature, and with the varying characters of individuals in society.

Those among us who maintain such views are far from gainsaying the benefits of science in the improvement of Medicine. What they seek is, to preserve the past fruits of experience from being overrun by the novelties of modern science, while they insist, that it belongs to every medical man to cultivate practical sagacity as well as science. They insist, that experience extends the number of remedies even more than science; and cannot help thinking, that some of our enthusiastic partisans of scientific medicine speak and act just now as those would have done in the time of Hippocrates, who should have made light of the fact, that a powdered shell cured heartburn, and asked men to wait for the palliation of that affection till, after the lapse of 2,000 years, the discovery should be made of the mutual neutralising property of an acid and an alkali.

There can be no doubt, that in this, as in other controversies, the contending parties do not clearly understand each other. All are agreed, it is to be supposed, that science—that is, the application of such sciences as physiology, chemistry, and physical science in general—can afford very material help in the improvement of medical practice. Still the controversy does not terminate. According to the one party, because improvements in the practice of medicine have been made by the aid of science, it is not, therefore, to be affirmed, that Medicine itself has become more scientific in its principles; for the mode of applying those scientific discoveries to Medicine may be strictly empirical, notwithstanding that they may rest on principles the most purely scientific. And they think the distinction here pointed at of greater importance than at first sight it may appear to be. And there is not much room for doubt, that one cause of the continuance of this controversy is, that what many contend for, as scientific Medicine, in opposition to what they consider as the result of mere wayward experience, is the simple application of all that is available in human science to the advancement of Medicine, without distinguishing between science applicable to Medicine, and what is strictly Medical Science. But the other party say, the distinction is broad and intelligible. For, say they, scientific Medicine can have no other correct signification than that which teaches the discovery of the treatment from the consideration of the nature of the disease, as in the case before referred to, of acid acrimony removed by alkali; while the science which enables us to appreciate new symptoms, and to present our remedies under more appropriate forms, is, or need be, no more than a valuable aid to purely empirical medicine. For example: wheat and the other cereal grains are known, by experience,—that is, empirically,—to be highly nutritious; but it could not be correctly said, that the theory or science of nutrition was improved, merely because the nutritive properties of those grains had been augmented by a better method of grinding them into flour or meal, owing to new discoveries in the science of mechanics. Neither, they continue, can it be said, when we employ the stethoscope, the microscope, or chemical analysis, for the more exact diagnosis of diseases, that we are extending scientific Medicine, —we are merely employing more exact methods of observation, founded on scientific discoveries. Each new variety of disease pointed out by these methods still requires, in general, to have its appropriate treatment determined by experience. Thus they urge, that rational or scientific Medicine, though not absolutely unknown, has as yet a very narrow basis, and that experience, as regards the effects of remedies, is very nearly the sole foundation of practical Medicine. Further, that the use of science in Medicine is not to enable us to determine, *à priori*, what remedies will cure such and such diseases, but to prepare us to avail ourselves, in the treatment of diseases, of all that the past experience of mankind has taught, and of all that our own opportunities of observation can afford,—and that thus no small office is assigned to science in the exercise of Medicine. There is, in short, they say, the greatest possible use for science in the preparation for practice,—that is to say, for treatment; but, in the treatment itself, that the ancient principle of doing, that which experience has taught to be useful, is the only safe line of conduct. They do not deny, however, that science can suggest, to a very considerable extent, modes of treatment for cautious trial, nor yet, perhaps, that this, in a limited sense, may be termed scientific medicine, and as often as a remedy suggested by science is sanctioned by experience, that a certain credit may be claimed for science. But they deny that there are many practitioners so gifted as to have much success in this line of practice. They also admit, that, in various ways besides, scientific knowledge, physical and chemical, as well as physiological, is capable of affording useful aid in the practice of medicine, without necessarily rendering that practice scientific or rational; that experience, for example, long ago determined, that burnt sponge is useful in bronchocele and scrofula; that chemical science, soon after the discovery of iodine, showed the existence of that substance in burnt sponge, and that a suggestion thus arose, which was quickly verified, that burnt sponge owed its curative power to the presence of iodine. That here, undoubtedly, we are indebted to chemical science for the introduction of iodine as a remedy in practice; but they deny that it can be justly contended, that the use of iodine in practice is an example of the exercise of rational medicine. Lastly, that the same thing is true o fmany other remedies, or that science, aided by the use of analogy, extends the lists of the Materia Medica, by suggesting probable uses for a drug, though its final reception, as a recognised remedy, rests solely on experience. Such is the form which the old contest between the Dogmatics and Empirics, so luminously treated of in the *Medical Times* some months since, has assumed among our brethren in Edinburgh for some weeks past.

SELECTIONS FROM FOREIGN JOURNALS.

THE MODE OF TERMINATION OF NERVES.

The skin of the frog consists of (1) A corium or derma of areolar tissue, the fibres of which are in horizontal layers, but join at certain points, and thus form canals perforating the tissue. (2.) A loose tissue, the fibres of which are united in every direction, and which includes the globular cutaneous glands imbedded in this layer. (3.) Epidermis, the deeper cells of which are pigmentary; while the remainder, as they approach the surface, show the ordinary varieties of shape and consistence. This skin is not everywhere attached to the body of the animal, but only at certain points; where thin membranes (mesodermata) tie it down, and conduct its vessels and nerves. Thus, under the skin there is a considerable space, which is clothed with a serous membrane, forming the undermost layer of all, and duplicatures of which constitute the mesodermata. Thus far to prepare the reader to follow the distribution of nerves in this skin. Hitherto Burdach has described a plexus of nerves on the under surface. Wagner has lately stated a partition of the primitive fibrils on the nictitating membrane of the frog's eye. But beyond this nothing is known.

The want of transparency has hitherto been a great barrier to the investigation of the nerves in the skin of the frog. This is remedied, not by acetic acid, but by splitting it into two laminæ, into which it is readily separated at the point of junction of the layers 1 and 2 just mentioned. The nerves may also be advantageously hardened with corrosive sublimate, by the aid of which the preparations may be kept useful a long time.

The bundles of nerves destined for the skin, protrude between the superficial muscles; and passing through the subcutaneous space, gain the under surface of the skin. Each bundle possesses a proper sheath, provided with nuclei. Some appear to be free, others enclosed in the mesodermata; there is no difference, except in the amount of areolar tissue which ensheathes them. The blood-vessels take the same course, and are mostly clothed with pigment cells.

Thus reaching the skin, the nerves pass between the derma and the serous membrane; covered, usually with some, often with many, pigment cells.

Each bundle of nerves is divided, and usually bifurcated, into subordinate branches. These again bifurcate, and, uniting with the neighbouring branches, form meshes of various polygonal shapes, so that the under surface of the skin is occupied by an unbroken, self continuous network of nerves. The mixture is so manifold, and, by repeated separation and re-union, so intricate, that each branchlet in the plexus consists of fibrils which reached the skin through many different bundles. This network we may call the *plexus nervorum interior seu profundus*.

From the bundles of this network spring many small and large branches, which pass into the canals of the derma previously mentioned; and thus arriving at the looser layer (2), disperse amongst the cutaneous glands, forming the *plexus nervorum superficialis*.

The next question is, "how do the primitive fibres behave in this network, and how do they terminate?"

The latter question remains in abeyance. Formerly, when the undivided character of the new fibril was regarded as ascertained, the question was mainly limited to the alternative of a free looped or a free termination, now it is known that the nerve fibril does divide; but we have no means of deciding whether any or all of its branches end by a free or looped extremity; whether they anastomose with each other, or with twigs of a different fibril. In short, the question is but amplified; the possible terminations are multiplied.

Only direct and careful observation will afford any conclusion, and, hitherto, the difficulties which encompass the subject,—difficulties in part arising from the nature of the substance of the nerves, partly from that of the organs they supply,—have

prevented any solution of the question. Thus, in the electrical organ of the torpedo, in which the most favourable circumstances are present, the last small branches are always traced with indistinct and vanishing outlines, into the basic substance of the organ; and any decision is thus rendered impossible.

In the skin of the frog, the primitive fibrils so rarely take a sufficiently isolated course to be pursued any great distance, that there is even less hope of making out their termination. But they divide, and these divisions occur in considerable number, and at most different parts of the integument. Arriving at the deep plexus, they take part in the formation of several meshes. But although particular fibres were followed for a considerable extent, they were never seen, either to recurve into one or other of the main trunks, or to end with free extremities.

The division of the fibrils, as hitherto seen, is solely dichotomous, although often repeated on the branches. A double type of partition seems to obtain; a fibril either splits into two twigs of equal size, or one of these is much larger than the other. One can scarcely avoid the notion, that in the latter case, the stem fibril gives a single branch, and then pursues its way, while in the former a real bifurcation occurs; somewhat analogous may be observed in the blood vessels.

The angles at which the branches are united to each other and to the stem fibril are worthy of note. They are sometimes obtuse, sometimes acute, some times nearly right angles. Not unseldom one of the branches takes the same direction as the stem; while the smaller of the two, usually breaking off at a nearly right angle, has the appearance of being the single branch. Branches of equal thickness generally form an equal angle with the stem.

The repeated division of the nerve fibres constitutes an unalterable fact, but it may be very differently explained.

Thus, one of the free fibres may be regarded as connected with the central organ, and the others as branches of the first and second rank; or one of the branches with the trunk may be regarded as the ends of a loop, from which a branch arises to bifurcate shortly afterwards; or an anastomosis between two terminal loops may be thus seen.

On further tracing these ramifications some were lost in the deep plexus; others extended through the dermal canals into the looser areolar tissue. One fibril bifurcated five times.

Supposing the sensitive nerves to act as conductors, and to transmit the irritation towards the centre, a solitary conductor will refer it to a *point*, a branched one to a *surface*. In the first case, the sensation is more limited and precise; in the second it is more vague. And if the two branches of one fibril or conductor were irritated by two locally separated bodies, but one impression would result; so, if branches of different nerves overlaid each other, but one impression would result.

Applying this to the integument of the frog, it would appear that an impression is only doubled when it irritates two places supplied by peripheric branches of nerves, which do not interfere with each other, or cover each other. It seems probable that an application of this to man would explain Weber's well known experiments.

Thus, sharpness of feeling and sensibility, are two different things. The skin of the back is sensitive, but is void of discriminating feeling; that by the side of the elbow joint is neither sensitive nor discriminating; that of the lips is both.

The conditions of these qualities appear twofold —the structure of the organ, the mode of division of the nerves.

The *sensibility* of a portion of skin depends—firstly, on the delicacy of the layer which covers the nerves; secondly, on the absolute number of the nerves. Whether this results from a great number of primitive fibrils, or from the splitting and separation of a few, since either of these conditions would result in a lively re-action of the sensitive surface from a slight irritation.

The *fineness* of feeling depends upon the local separation of similar irritations in the sensation. Here all that is necessary in the organ itself is space for the distribution of nerves; while the relative number of primitive fibrils constitutes the most important condition. The more of these present, so as to give separate impressions of different parts of a surface, the finer the perception of the organ. The existence of a substratum of solid consistence beneath these nerves materially assists fine feeling, by affording an object for pressure. The tongue, as contrasted with the finger, may exemplify this.

The nerves are usually constricted at the point of bifurcation, but this condition, like that of the varicose fibres of the brain, is probably abnormal, since in the air-bladder of the pike, examined in a fresh state, nothing of the kind was present; while decomposition increased the constrictions to downright separation.—(Abstract of a Paper by Johann. N. Czermak, in *Muller's Archiv.*, No. III., pp. 251—271.)

THE MEDICAL TIMES.

SATURDAY, DECEMBER 15, 1849.

SECRET place-hunters, who have tried various bye-paths to Hospital appointments, and who have no hope of advancement but in a cringing subserviency to the Sanhedrim in Lincoln's-inn-fields, have been covering this august body with eulogies for their generosity and their wisdom. They have, at the same time, artfully taken care, to whistle the mocking-bird's note of Reform, that the abject selfishness of their adulation might not be discovered. The Council are described as being "shielded by the armour of truth and justice." *Mirabile dictu!*—their opponents, as "corrupt, mercenary, and ignorant assailants;" and the Ajax of the Council as the "laudable, energetic, and persevering" Mr. Guthrie. This charming triplication of adjectives is the essence and the strength of a good style; and far be it from us "to hint a fault, or hesitate dislike," when this learned Theban has evidently taken so much pains to hammer conviction into his readers by culling promiscuously from Walker and Mrs. Malaprop, the highest authorities upon language recognized in this country.

If, however, we are to believe all we read, we must conclude, that a great reform will, at last, be accomplished; and upon the principle that the vilest sinners always make the most devoted saints, the Council of the College have become the paragons—the shining lights of a new reformation. We have always been hard of faith, and have but little confidence in sudden conversions.

The Council, we are told, are about to confer a twenty years' franchise as a boon upon the Members; and we are further informed that this vast concession ought to be received by them with a paroxysm—an actual epilepsy of delight. Poor Members! we can imagine the horrible contortions of joy into which your frames will be thrown by the reception of this astounding intelligence! A godsend does not come very often, but when it does come, let gratitude have its saturnalia! We should be sorry to play the cynic at so jubilant a festival.

In the first place, then, the College will grant the Fellowship, and therewith the franchise, to Members of twenty years' standing. Can this restriction,—or concession, if you please,—possibly give satisfaction to the General Practitioners of Medicine and Surgery? What superior wisdom does a man of forty-five possess over a man of thirty-five, that can so eminently qualify him to elect a Member of Council? Is it not insulting to suppose that an educated surgeon,—a man with information, sense, and judgment enough to cure disease, and to save lives, is yet too ignorant to be able to choose the man best qualified to guard his interest and spend his money until he has been twenty years, or more, on the Register? This is the liberality of the Council of the College, which we are called upon to admire and to confirm.

Again, how many of the Members, even of twenty years' standing, will enjoy this distinguished privilege? Rumour says, that it is intended that none shall be admitted to the Fellowship, but those who can obtain a testimonial of moral character or fitness from at least *six Fellows!* A modest requisition, truly! Do our readers think that one Member in ten will be on sufficiently intimate terms with half-a-dozen of the Fellows, to ask from them a certificate of character; and, if he were, is it to be supposed that he could condescend to such a humiliating act? Let every country Practitioner figure to himself this position.

The list of Fellows will, by this cunningly-devised restriction, be necessarily kept small—contracted, in fact, to its narrowest limits; and, as for any real advantage that is likely to accrue to the Profession at large from the alteration, we have not the sagacity to perceive it. Will the rapacity of quacks be checked? will Surgeons be able to claim in law? will the educational question be advanced one step? or, will any one great question be brought nearer to a settlement?

Let us narrow the question, however, to the mere claims of the members of the College, and of those in particular who were members antecedent to the great iniquity of 1843. It has been demanded, as a right, that all those gentlemen should be admitted to the Fellowship, on the simple ground of their membership alone. This was a just and reasonable claim. It had its foundation in common honesty, and the Council, by their own Act, have admitted the equity of its principle. "But," say they, "although we recognize the justice of your demands, we cannot humble ourselves to a full acknowledgment of our own errors, and we, therefore, determine that only men of twenty years' standing shall be invested with the fellowship, and not even they, unless they can procure a testimonial from six Fellows and are willing to pay ten guineas for the honour." Members of the College! the insulted of 1843! have you so far forgotten your old wrongs that you can tamely submit to new insults? Can you, who have demanded the free restitution of that original equality, which, as Members of the College, all enjoyed, be content to submit to the new indignity of hawking a begging testi-

monial from door to door, and to supplicate for that position as *a favour* which is yours by an *indefeasible right*? Can you, who have already *purchased* equality of privileges in the College, by paying the same sum as any of the selected Fellows, or any of the privileged Council themselves, be induced, by any artifice, to *buy over again* your unquestionable rights, or suffer an unjust and unmerited exclusion? What are the benefits that the Council propose to confer upon you? *Perpetual exclusion* on the one side, or HUMILIATION and TAXATION on the other! Have you anything to be thankful for? A canine docility is not yours, and you will not caress the hand that smites you.

Well, then, Gentlemen, you shall have the Fellowship, if, upon these terms, you have the spirit that will accept it; and what advantage, after all, will the Profession obtain? Will a Fellow acquire an eligibility for the Council, or for a seat at the Examining Board? Do not be deceived. If he practise as a General Practitioner,—if his hands be polluted with the scent of rhubarb or rose-water, or his sleeve defiled by the examinating gush from a mother's womb,—he will lose his title to the higher offices and distinctions of his College. His humanity will be a blot upon his escutcheon,—his operative skill a disqualification for surgical honours,—his science a bar to his advancement,—and his usefulness a derogation from the dignity of his calling. He will be an outcast from the precincts of purism. Be ignorant of all you ought to know, and you shall be exalted to high places. If you cannot detect Epsom salt from oxalic acid, or describe the difference between a pair of midwifery forceps and a tailor's scissors,—if you can display a certificate, that, in consequence of your ignorance, you had guiltily permitted a woman in labour to perish in her trial, when the aid of surgical science would have saved her life, you will have shown your best and almost your only title to a seat in the Council of the College of Surgeons.

Are these anomalies to continue? Whilst such scandals as these are unredressed, shall we toss our caps in a frenzy of enthusiasm at the liberality of a reforming Council? We say, that nothing has been conceded that has not been forced, and that you will get nothing, either in fact or promise, without contending for it with all the energy of your own stout manhood. There is more common sense, more honesty, and more independence abroad, than some persons give the Profession the credit of possessing. We have never found these great qualities wanting; for, accustomed always to confide in our own principles and instincts, we have fearlessly appealed to yours, and have never been disappointed. We have never consented to folly or wrong because it has been the fashion or the wickedness to praise either, and have generally found, that men, upon questioning themselves, have been of our opinion.

What, then, do we advise you to do? Reject nothing that is an improvement upon your present position: but remove all absurd and oppressive restrictions, protest against unnecessary taxation, and strive to open the franchise much wider than is now contemplated. More than this, you must co-operate to obtain a sound and comprehensive reform for the whole Profession.

MR. BOTTOMLEY'S EXPLANATION.

It appears that the mis-statements of the proceedings at the Hanover-square Conference have not terminated with our exposure of them. The doings of Mr. Bottomley called forth the authoritative notice of Mr. Clifton the Chairman of the meeting, who required that the statements contained in the letter to a contemporary Journal, as they were utterly at variance with the truth, should be corrected. This was, of course, a very awkward demand, and very awkwardly has it been answered;—if answered it can even yet be said to be.

Mr. Bottomley, it seems, attempted, in his usual lucid way, to make some explanation in expiation of his offence, and published, in another journal, what he was pleased to call his "correspondence" with Mr. Clifton, in which a letter was introduced which that gentleman never received. This letter is, of course, intended as an answer to Mr. Clifton's charge of publishing incorrect statements, but we cannot pity the incoherence of its arguments more than we do the want of courtesy and the ignorance of good manners which could permit Mr. Bottomley to act in a mode so inconsistent with the ordinary usages of society as that which has marked his conduct throughout the whole of these transactions.

THE FREE HOSPITAL.

The publicity which the daily papers have afforded to the late trial (a) in the Court of Queen's Bench, renders it unnecessary for us to give more than a very brief abstract of the proceedings.

A child of twelve years fractures its thigh bone in the upper third: it is taken to a Hospital, and, one month after, is attacked with scarlet fever. From such a combination of disorders the reparative process is suspended, and the protracted recovery is only completed at another Hospital. The father of the patient, the grateful recipient of all this priceless kindness, heaps a series of libels and insults on one of his benefactors, and at length mulcts him of a large sum of money, by dragging him into a court of law on a charge of malapraxis.

The main constituents of this general charge are, a want of due surgical skill, both in setting the bone and retaining it in apposition; and neglect by the subordinate nurses. The latter was alleged to have resulted not only in a privation of cleanliness, but in the addition of a venereal disease to the previously existing maladies. The plaintiff backed his case, by recounting some attempts to obtain condonation of these injuries by the defendant and his father.

Every one of these statements appears to have been amply disproved. High surgical authority was adduced to show, that there was nothing in the condition of the child for which the circumstances above mentioned would not amply account. The want of cleanliness was shewn not to have resulted from want of attention. The statement of the venereal disease, denied or disbelieved by the plaintiff's counsel, was not substantiated by any evidence. And, finally, the alleged attempt at compromise and concealment, even had it been really made, would prove nothing; the desire to protect reputation is common to innocence and guilt.

We congratulate the defendant and the Profession generally on the result of this trial. If the ignorant and the malicious are to pry into the details, and criticise the machinery, of a science with which they are utterly unacquainted; if their brutal stupidity is to misconstrue every circumstance into a crime, and reproach the medical attendant with all the phenomena of disease,' who would be found foolish or impious enough to accept medical functions, and thus render himself personally responsible for the speedy recovery of every patient entrusted to his care? Such a monstrous proposition, and such a patient, could only be answered in the words of the King of Israel, "Am I God to kill and to make alive? Consider, I pray you, and see how he seeketh a quarrel against me."

(a) *In forma pauperis*. Quelch *v*. Wakley, *Times* of December 11.

PROGRESS OF CIVILIZATION.

We are happy to see that, for the first time we believe for many hundred years, the remains of an English Sovereign have been permitted to pass to the common resting-place of frail humanity, without being subjected to the barbarous ceremonies with which we are accustomed to *dignify* the funerals of our rulers. Why, when the body has finished its task of furnishing a mansion to the soul, we should attempt to arrest its natural decay, and preserve the material—as if, without the spiritual body, it were more than a mass of dust—we could never determine. It might be very well for the mighty Pharaohs, who thought themselves of finer clay than the slaves who surrounded them, to build pyramids, and to cause their dead bodies to be embalmed in the vain attempt to preserve, even after death, those privileges which separated them from the common herd. But that one who knows that between the peasant and monarch there is no real interval,—that each alike comes of the earth and returns to the earth,—should yet attempt to make a difference between the royal and the plebeian dead, is, to say the least, marvellously inconsistent. It is a proof of the puerility with which men cling to, and attempt the perpetuation of distinctions between man and man, which, nevertheless, the last sob of life inevitably destroys.

So, also, the process of "lying in state,"—which had a real meaning in ancient times, when it was necessary to satisfy the peers that their feudal chief was really dead, and that his successor had, therefore, a just right to their homage,—has lost all utility in these days, when we do not suspect Sir Robert Peel or Lord John Russell of forcibly imprisoning Queen Victoria, or of unjustifiably spreading a report of the death of the Prince of Wales! There is no fear now of any injury being inflicted on a Sovereign which "lying in state" can possibly remedy. The absurd ceremony serves only for the gratification of a puerile curiosity, or for the amusement of idle pleasure-seekers. We have ceased to stick the heads of our criminals on Temple-bar; it will not be long before we shall.

class in the same category of barbarisms of the olden time, the exposure of Royal Dust to the gaze of vulgar loungers.

It is a step in the right direction that the mortal remains of the lamented Queen Dowager have been allowed quietly to pass to their resting-place, without being disturbed by indecent manipulations and senseless ceremonial.

ARCHITECTURAL EXPENDITURE OF THE NAVY AND ITS MEDICAL STAFF.

WHOEVER has read the letter of Sir Charles Napier lately published in the *Times* Newspaper, on the subject of Naval Architecture, will probably agree with us, in wondering at the contrast between the ninety millions of money spent within a few years in building ships and then pulling them to pieces, and the niggardly pay and pertinacious discomfort awarded by the same authorities to the Surgeons and Assistant-Surgeons of the Navy. The ungracious arrangements for their comfort, stand out in bold and prominent contrast with the lavish outlay in the building, and seeming indifference to the demolition of vessels costing such an enormous amount of money. If even a small part of this vast sum had been appropriated to the fair remuneration and adequate accommodation of those of our medical brethren "whose lot is cast upon the waters," it would have been a boon to the service, and would have removed one of those evils to which we have so often alluded, and under which our naval surgeons and assistant-surgeons have so long suffered. The voice of the public will soon be heard with a preventive effect in the ship-building experiments, and then will be the time for this ill-treated but meretorious portion of our Profession energetically to insist upon a just consideration of their claims. We shall be happy to receive communications on the subject, and give all the aid in our power to so good a cause.

REPORTS OF SOCIETIES.

WESTMINSTER MEDICAL SOCIETY.

Nov. 24, 1849.

F. HIRD, Esq., President, in the Chair.

ULCERATION OF THE TONSILS; SECONDARY HÆMORRHAGE, AND LIGATURE OF THE COMMON CAROTID.—OVARIAN DISEASE.

Dr. Daniell spoke of a case of enlarged scrofulous glands in the neck, which he had lately seen in the Middlesex Hospital, under the care of Mr. de Morgan. An abscess had formed and burst. After the patient had been in the Hospital some time, and the ulcer following the abscess was partly healed, the patient complained of sore-throat, the left tonsil being enlarged and inflamed. This continued for a few days, and then ulceration commenced, and made progress. Arterial hæmorrhage, to the extent of two pints, took place from the ulcerated surface, and it was deemed necessary to tie the common carotid, which operation was performed by Mr. de Morgan. There has not been any return of the hæmorrhage since. He (Dr. Daniell) had seen the patient twice since, and found that he was going on well. The centre of the incision which had been made was through a diseased gland; and that part had sloughed; the dead part, however, had separated, and the structures beneath looked healthy. It was difficult, he said, to determine the artery whence the hæmorrhage had issued. The case, in his opinion, was a rare one for hæmorrhage to arise from such a cause.

Mr. I. B. Brown read a paper on the diagnosis of Ovarian Dropsy. Mr. Brown began by observing, that the importance of this subject can scarcely be exaggerated; for, whatever be the treatment, a knowledge, not only of the presence of ovarian disease, but of the precise nature of the disease, is of the greatest moment. Mr. Brown did not on this occasion intend to dwell on ovariotomy, nor to allude to the many cases where the abdominal cavity had been opened, and no ovarian disease whatever had been found to exist. He intended to mention some cases of error in diagnosis which had come under his own personal observation, but before giving these cases, he briefly narrated the general and special signs of ovarian dropsy, both unilocular and multilocular.

The General Signs of Ovarian Dropsy.—Amongst these we must place emaciation of the neck and shoulders, expression of the countenance peculiar, indicating, in a marked manner, the presence of this disease. The face is elongated, thin, and partially shrivelled; anxiety and care are strongly depicted on it. The angles of the nose are drawn downwards, the lips are thinned, the mouth loses its curves—the angle being drawn downwards; the cheeks are furrowed, the eyes are remarkably defined, owing often to the sunken space between the eyelids and the bony margin of the orbit; the skin is thin and pale—in short, the whole of the cellular tissue of the face is atrophied; but, unless the disease be malignant, the skin has not the peculiar aspect which it acquires in malignant disease. The extremities are seldom swollen, as in ascites, and consequently the patient can walk about with comparative ease. There is generally also but little disturbance to digestion, and usually adequate action of the liver. Respiration, and the action of the heart are less disturbed than in ascites, but the heart's action is feeble, owing to the diminution in the whole mass of the blood.

The *special* signs are—First. We can generally trace the commencement of this disease from one of the ovaries deep down in the iliac fossa. A tumour between the rectum and vagina may be felt, either through the walls of the vagina or the rectum; not excessively painful, but elastic. On firmly pressing it, especially at the commencement of the formation of the tumour, you can get it between the thumb in the rectum and the middle finger in the vagina; but you can also frequently feel an egg-like enlargement around the ovary, through the abdominal parietes, especially if the thighs are flexed on the abdomen so as to relax the muscles. This tumour gradually and definitely increases, still maintaining a rounded outline, ascends from the pelvic cavity to the abdominal, rises in front of the bowels, distending the abdominal parietes, and sometimes reaching the ensiform cartilage, pressing up the liver, stomach, pancreas, and spleen, so as to elevate the diaphragm, and thus contract very considerably the thoracic space. This tumour, which, as it ascends, becomes more fluctuating, occupies the side from which it originates; but, whilst it throughout retains a preponderance towards that side, it gradually extends to the opposite. The veins of the abdomen are generally much increased in number and size. The sac containing the fluid being circumscribed, the indications afforded by percussion are circumscribed also, and the sounds on percussion are, of course, dull over the sac, and resonant over the surrounding intestines. On examination per vaginam, fluctuation can be generally felt through its walls, and the vagina itself is elongated and drawn up, sometimes even under the arch of the pubes; the uterus is also either drawn up or pressed back on the rectum. The cyst is generally round and smooth on feeling it through the parietes of the abdomen, and moveable from side to side, and is not materially altered by change of position, either recumbent or upright. These special signs apply more particularly to unilocular ovarian dropsy. In multilocular we almost invariably have an uneven and irregular surface of the cyst, and generally one or more solid tumours which appear inelastic and without fluid; but, in very many cases, these tumours will be found to be additional cysts containing fluid; they are tense, owing to the pressure of the fluid in the larger one. He had frequently found this to be the case, and it is proved by evacuating the contents of the larger cyst, and again introducing the trocar through the canula still in the opening, thrusting it into the apparently solid tumour, and finding immediately an escape of fluid. On examining a multilocular cyst, fluctuation is not distinct if you examine the entire cyst; but, if you tap over any one of the sacs, fluctuation is apparent, but only over that one, not being at all communicated to the adjoining cyst or cysts, where, however, the fluid is gelatinous or albuminous, fluctuation cannot be so readily felt. The same observation applies to the cysts which contain thick cheesy matter, mixed with pus, and somtimes also with hair. He lately met with a case where fluctuation was only perceptible at one spot externally, and at one other spot, through the walls of the vagina. This case, which his friend Mr. Nunn saw with him, as well as Dr. Locock, proved, on tapping, to be filled with a thick cheesy matter, mixed with pus and hair, which escaped with great difficulty through the canula. But, there are also distinct solid tumours in connexion with these fluid ones, and then there is no sense of fluctuation. This observation applies both before and after evacuting the contents of the fluid cysts. Having ascertained the nature of the tumour so far as to say whether it is unilocular or multilocular, the next important subject is, as to the presence of adhesions. In examining for adhesions, Mr. B. directs the patient to be laid in the horizontal posture, and to have the thighs flexed on the abdomen, so as to relax the abdominal parietes. He then moves the cyst from side to side. If this be readily done, there are no adhesions. Again, he place his hand firmly on the relaxed parietes, and moves them over the cyst. If they move readily, he knows there are no adhesions on the upper and lateral surfaces of the cyst. Again, as the parietes are thin in this disease, he grasps and puckers them up and then moves them over the cyst, and also sees if they gather up readily without raising the cyst itself. If he finds these three indications, he determines that there are no adhesions. Another plan, for which he is indebted to his friend Dr. Sibson, is based on the extent to which the contents of the abdomen are forced downwards during a deep inspiration, by the descent of the diaphragm. If there be no adhesions in front, the upper boundary of the ovarian tumour descends to the extent of an inch during a deep inspiration, the place previously occupied by the tumour being taken up by the intestines, consequently, if you percuss over the upper part of the tumour, a dull sound is elicited during ordinary respiration, but when the patient takes a deep inspiration, an intestinal resonance is there perceptible.

Mr. Brown then alluded to those diseases which may be mistaken for ovarian dropsy, and slightly remarked on their peculiar signs, viz.—1st, retroflexion and retroversion of the uterus; 2nd, tumours of the uterus; 3rd, ascites; 4th, pregnancy; 5th, cystic tumours of the abdomen; 6th, distended bladder; 7th, accumulation of air in the intestines, especially if there have been chronic peritonitis, leaving some ascitic fluid; 8th, enlargement of the solid viscera of the abdomen, the liver, spleen, and kidneys; 9th, accumulation of fæces in the intestines. Mr. Brown dwelt on the leading characteristic signs of these different diseases, and showed how they differed, not only from each other, but more especially from ovarian dropsy.

He then narrated the case of a lady who was supposed to suffer from ovarian dropsy, on whom an experimental incision was made through the parietes, to ascertain if extirpation could be effected, when it was ascertained that no cystic tumour existed, but a solid, firmly adherent one attached to the ovaries, with a roughened upper surface, which, rubbing against the peritonæum, caused the secretion of fluid.

The second case was one of ascites, depending on diseased liver, in which twenty London medical men had been consulted; eighteen pronounced it ovarian dropsy, and one proposed extirpation as the only remedy; this patient is now convalescent, after a year's medical treatment directed to the liver and kidneys.

The third was the case of a young lady fourteen years of age, who was supposed to labour under ovarian dropsy, and who was proved, by a *post-mortem* examination, to have suffered from chronic peritonitis, complicated with impacted fæces in the intestines, and some ascitic fluid in the cavity of the peritonæum.

Mr. Travers, jun., inquired of Mr. Brown, whether he had seen or heard of a tumour resulting from retained menstrual fluid from imperforate hymen, being mistaken for ovarian disease? There was such a case, many years ago, in St. Thomas'

Hospital, under the late Dr. Williams. Examination *per vaginam* detected a fluctuating tumour, which was freely opened with an abscess lancet, and a large wash-hand basin was filled with the retained menstrual fluid. The patient was in bad health, and presented general symptoms which led to the belief that the tumour was ovarian. Such a case Mr. Travers thought might again be mistaken for ovarian dropsy.

Mr. Hunt said, that few medical men had not met with cases of enlarged abdomen which had been mistaken for ovarian disease. He had had two such cases himself. One occurred in a middle-aged woman, who complained of spasmodic pain in the abdomen; there was a tumour which occupied chiefly the position of the left kidney, but extended from the ribs to the pubes; it was irregular, nodulated, and firm, and gave no sensation of fluctuation. A physician, who was consulted about the case, looked upon it as ovarian. His own impression was, that it was a collection of fæcal matter, and, with the view of removing it, he injected three or four pints of warm water, with salt, through O'Beirne's tube. There were not much fæces discharged in consequence, nor was there any diminution of the tumour. The injection was repeated on several occasions, with a similar result. Iodiine was then used externally, and arsenic given internally, but without any improvement, and at last all medicines were discontinued. The tumour remained stationary for some time. He was one day sent for, and, on examination, found that all traces of the tumour had disappeared, never to return. She had passed a large quantity of water, slightly tinged with blood, during the previous twenty-four hours. The other case occurred in the person of a married woman, who had a tumour at the lower part of the abdomen, also said to be ovarian. He was called in to see her, on the supposition that she was in labour; the pains resembled those of parturition, but an examination *per vaginam* showed that she was not even pregnant. The uterus was of the usual size, and the vagina small. An old woman, who was present, said she could see and feel the child, and stripped her to show it him. An opiate removed the pain, and she went several miles to see a physician, who said she was in the family way. By free purgation, with repeated doses of aloes, all signs of the tumour were removed.

Mr. Druitt related a case in which ovarian disease had been mistaken for pregnancy, and every preparation made for labour; the pains occurring, were regarded as indicative of approaching parturition. A sound resembling that of the fœtal heart was heard in the tumour. The pains afterwards went off, and, after lingering some time, the unfortunate patient, who had been violated, sunk. An examination of the body showed that the disease was ovarian. [As this case has been published by Mr. Challice, the surgeon in attendance, we do not think it necessary to give the details as fully as Mr. Druitt did to the Society.]

Dr. Murphy had met with cases of large cysts, or tumours, in the abdomen, resembling the pregnant uterus, and accompanied by sounds imitating those of the fœtal heart. He believed that the pulsation was caused by the beating of the patient's heart, and might be discovered to be so, by comparing the pulse of the patient with the supposed fœtal pulsations. He wished to hear from Mr. Brown, how he ascertained the existence of adhesions posteriorly; he thought they could not be recognised readily; he had seen one case in which they existed. With reference to one of the cases mentioned by Mr. Brown, in which Mr. Lane had been consulted, both having made a very careful examination, he could not understand how such a mistake had been made as to treat it as ovarian, when it was simply ascitic. It was very true, that when ovarian tumours and ascites existed together, the diagnosis was very difficult.

Dr. Tilt alluded to the difficulty of diagnosis in ovarian tumours, which, he said, was confirmed by daily experience. The distinction between pregnancy and ovarian disease was one of the most important. Sometimes patients intentionally lead us astray. He remembered the case of a single woman, twenty years of age, under Rayer, at La Charité, with a very voluminous abdomen. Velpeau and others saw her. Some said she had ovarian dropsy, and others, fibrous tumour of the uterus. She was examined daily, but no satisfactory opinion was arrived at. One morning she was delivered of a child. Such cases are not infrequent. Other cases may offer great difficulty in the diagnosis. Ladies who have not borne children for many years, and who are supposed to be past the child-bearing age, may consult a practitioner for a gradually increasing tumour of the abdomen, which may be regarded as ovarian or as some other disease, but which, after all, may prove to be pregnancy. These cases are far from being uncommon. A case in point was that of a lady in the country, who, under such circumstances, and from the opinion that was given her, thought herself in such danger, that she made her will. She was ultimately delivered of an infant. In another case, also supposed to be ovarian disease, the lady was ultimately confined, and the child was still-born—killed (Dr. Tilt said,) by the treatment adopted to cure the supposed disease. It was important to know how to avoid such mistakes. We find under the microscope in the fluid contained in ovarian cysts, blood globules, epithelial scales, false membranes of various degrees of consistence, &c. All these, however, may be found in every kind of cyst. There are, beside these, certain appearances which are met with only in ovarian cysts; namely, a peculiar cell-like appearance, with granular bodies, which seem to separate from the cells, and swim in the circumambient fluid. They have been discovered not only in the ropy or tar-like fluid, but also in the diaphanous or serous contents, the difference being, that in the latter they are very scarce, and far between, and in the other they are very abundant. Their existence has been proved by Quekett and Bennett of Edinburgh and others. As yet, however, they have been found in twelve or fifteen cases only,—not a sufficient number to build a law upon. If it should prove that these bodies exist in the ovarian fluid in every case, we might then, in doubtful instances, by an exploratory puncture procure some of the fluid, and from the presence or absence of these bodies deduce the nature of the disease. This, indeed, has already been done by Dr. Bennett of Edinburgh, who determined a tumour to be ovarian, from the results of such an examination of the contained fluid. Until our diagnosis of ovarian cysts be better founded than it is at present, he (Dr. T.) thought that we are not justified in performing such a serious operation, as that of the removal of the diseased growth. It might happen, as it has already, that the operation might be commenced, and yet no tumour be in existence.

Dr. Sibson commended Mr. Brown's paper, with respect to the diagnosis of adhesions with ovarian cysts, and then referred to the resonance which takes place above the tumour, on taking a deep inspiration, which he attributed to the presence of some of the hollow intestines, pushed downwards by the descending diaphragm during the inspiration. This he regarded as a valuable symptom in diagnosis, showing that adhesions do not exist; at all events, not in front. Dr. Sibson mentioned cases in which he had applied this test, and he believed that the correctness of the diagnosis was verified afterwards in each case.

Dr. Ogier Ward stated, that a woman, past the child-bearing age, had consulted him for an abdominal tumour, which commenced on the left side. Not being able to make out its character, he used the exploring needle, and drew off a quantity of fluid containing epithelial scales, which the microscope showed to resemble those found in the white matter on newly born children. The examination *per vaginam* showed elongation of the uterine neck, the anterior lip of the os being pointed. After death the uterus was found to be full of this peculiar matter, containing, besides a tooth and some hair. He (Dr. Ward) was convinced, he had pierced the uterine cavity with the needle, but no evidence of subsequent inflammation could be discovered.

Mr. H. Smith alluded to two cases illustrating the difficulty of diagnosing the existence of adhesions. In one, the tumour being very large, the presence of extensive adhesions was predicted, and the operation considered to be inadmissible; but it was afterwards ascertained that none existed. In the next case he was requested to assist a surgeon in the removal of an ovarian tumour; the incision was made, when the tumour was found to be adherent in every direction, so that its extirpation could not be practised. The incision was sewn up, and the patient recovered from the effects of the operation.

Dr. Daniell was of opinion that in some cases it is better to be ignorant of the nature of a tumour, than to explore its contents with a needle, when it is doubtful whether it contains fluid. A person is nearer the truth who knows nothing, than he who believes what is false. The diagnosis between ovarian dropsy and ascites was difficult, but it might be aided by bearing in mind that there was less difficulty of breathing in the former than in the latter, and that by placing the patient on her side in the former disease, the fluid would gravitate to that side.

Mr. Brown remarked, in answer to the different speakers, that he had not seen such a case as that mentioned by Mr. Travers, jun., but would make a note of it. It was important. Mr. Hunt's case was probably one of obstruction of the ureter, causing distention of the pelvis of the kidney of that side. Fœtal pulsation alone was not a reliable sign of pregnancy. With respect to adhesions of the tumour posteriorly, he had not met with any such cases. Adhesions chiefly occurred in the upper and lateral parts of the tumour; whatever treatment was adopted, the existence of adhesions posteriorly, was a matter of little practical importance. Mr. Lane's case he did not see more than once, and was not present when the exploratory incision was made. He had seen four or five cases of ovarian cysts, complicated with pregnancy, but had not alluded to them for want of time. The observations made by Dr. Tilt, on the microscopic investigation of the contained fluid in ovarian tumours, he regarded as of great importance. He had himself been occupied in the prosecution of that study for the last two years, with certain results, but his cases were as yet too few to draw any practical conclusions from them.

Death from Chloroform.—Another death from the exhibition of chloroform has occurred at Shrewsbury. The patient was a poor Welch girl named Jones, under the care of Mr. Clements, who administered chloroform to her, prior to the extirpation of the eye-ball. It is said, that only one-third (ʒj) of the usual quantity was given. Death was almost instantaneous. Apoplexy was said to be the cause. We trust Mr. Clements will publish the particulars of the case, with the *post-mortem* appearances. Judging from the disease for which the operation was to have been performed, and the alleged cause of death, we presume that the brain was more or less unhealthy.

HEALTH OF LONDON DURING THE WEEK ENDING DEC. 8.

The Registrar's Weekly Return appears this week, for the first time since June 1848, without a death occurring under the head Cholera. Simultaneously, however, with this fact, we have an increase from typhus over the average of five autumns, but a remarkable decrease on other zymotic diseases.

The total of deaths registered (1053) exceeds those of last week by 122, but are less than the average of five years by 109. A gradual increase has taken place in the last four weeks, when the deaths respectively have been 878, 892, 931, and 1053, and the Registrar states that "the causes of the increase may be discovered in the fact, that whereas deaths from epidemic diseases in these four weeks were respectively 204, 178, 173, and 203, those caused by diseases of the respiratory organs (chiefly bronchitis and pneumonia) were 134, 170, 194, and 203, showing a gradual rise towards the average, which is 214." Influenza appears to be on the increase as to former weeks. A man is reported to have died in Norwood of glanders, caught from a diseased horse.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Dec. 8, 1849.

Causes of Death.	Total.	Average of Five Autumns.
All Causes	1058	1162
Specified Causes	1049	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	203	307
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	61	49
Tubercular Diseases	170	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	120	135
Diseases of the Heart and Blood vessels	50	40
Diseases of the Lungs, and of the other Organs of Respiration	203	214
Diseases of the Stomach, Liver, and other Organs of Digestion	61	65
Diseases of the Kidneys, &c.	11	11
Childbirth, Diseases of the Uterus, &c.	12	10
Rheumatism, Diseases of the Bones, Joints &c.	9	8
Diseases of the Skin, Cellular Tissue, &c.	2	1
Malformations	...	4
Premature Birth and Debility	25	23
Atrophy	18	18
Age	54	67
Sudden	8	12
Violence, Privation, Cold, and Intemperance	36	36
Causes not Specified	4	4

The following is the number of Deaths occurring from some of the more important special causes:—

Apoplexy......	22	Heart	46	Phthisis	135
Bronchitis ...	86	Hooping cough	18	Pneumonia ...	68
Cholera.........	...	Hydrocephalus	24	Scarlatina	32
Childbirth.....	9	Influenza	9	Small-pox	5
Convulsions...	40	Liver	13	Stomach	8
Diarrhœa.......	17	Lungs	10	Teething	8
Dropsy.........	25	Measles	29	Typhus	51
Erysipelas ...	11	Paralysis	25	Uterus	3

BIRTHS AND DEATHS.

	Births.	Deaths.	Births over Deaths.
Males	710	589	121
Females	628	514	114
Total......	1338	1103	235

METEOROLOGY OF THE WEEK.

Day.	Mean of Barometer.	Mean of Thermometer. Dry.	Ditto. Dew Point.	Difference between the Mean Temperature of the day and the same day on an average of 7 years.	General Direction of Wind. A.M.	General Direction of Wind. P.M.	Amount of Horizontal Movement of the Air. Miles	Rain in Inches.	Electricity.*
Sunday	29·458	47·9	45·9	+ 4·9	S	S. & S.E	120	0·40	Negative electricity with strong tension was exhibited for the most part throughout the morning of Wednesday during rain. Positive with moderate tension was shown at about noon on Thursday; and positive with strong tension on Saturday at 9 p.m., nothing shown at any other time during the week.
Monday......	29·360	39·6	37·9	− 2·7	S.E. & E.N.E.	N.E	125	0·41

MEDICAL NEWS.

Royal College of Surgeons.—The following gentlemen, all members of the College, having undergone the necessary examinations, were admitted Fellows of the College, at the meeting of the Council, on the 7th instant:—Messrs. Walter Goodyer Barker, Worthing, Diploma dated Oct. 25, 1839; Frederick John Butler, Winchester, May 8, 1840; George Washbourne Charleton, Gloucester, July 3, 1835; William Druitt, Wimborne Minster, Dorsetshire, July 30, 1841; Nathaniel John Dampier, Woburn-place, Russell-square, May 24, 1844; Sharp Mountain Girdlestone, Lincoln's-inn-fields, Jan. 3, 1845; George William Hind, Alfred-place, Bedford-square, Nov. 3, 1827; Raymond Levi Haynes, Holloway, March 5, 1841; Richard Hodges, Rochford, Essex, July 31, 1843; Edward Charles Hulme, Maisonette, Totness, Devon, April 12, 1844; Robert George Mager, Highgate, May 15, 1829; Edwin Morris, Spalding, Lincolnshire, April 22, 1839; John Marshall, Crescent-place, Mornington-crescent, Aug. 9, 1844; William Potts, South Audley-street, May 8, 1839; Augustin Prichard, Red Lodge, Bristol, Oct. 30, 1840; Edward Ray, Dulwich, Surrey, April 5, 1839; Ebenezer Smith, Billiter-square, March 18, 1831; George Carrick Steel, Chadwell-street, Islington, July 3, 1840; Henry Smith, Caroline-street, Bedford-square, April 24, 1846; John Wiblin, Southampton, June 2, 1837; and Thomas Henry Wakley, Guildford-street, Russell-square, July 25, 1845. We understand, that out of the twenty-two gentlemen who presented themselves for examination only one was rejected.

Obituary.—Last week, Mr. Scuddamore, Surgeon, of Prescot. The unfortunate gentleman was killed by the accidental discharge of a loaded pistol, as he was drawing it from his pocket. The contents entered the groin. Medical assistance was sought, but he died almost immediately. At his residence, 16, Park-walk, Chelsea, Matthew Heir, Esq., late Surgeon to the 66th Foot, aged 78. At Abbey Holme, Cumberland, on the 24th ult., of cholera, C. Maling, Esq., Surgeon, aged 34. At Barbadoes, on the 22nd October, Thomas Whitelaw, Esq., Surgeon, Royal Artillery. On the 20th of October, at Waltair, East Indies, E. L. J. Gaine, Esq., surgeon, H. E. I. C. S. At North Egremont, Cheshire, Mr. John Cheesbrough, Surgeon. On Saturday, the 1st instant, at Llangollen, aged 73, Chas. Worthington, Esq., Surgeon.

War Office.—3rd West India Reg.—Staff Assist.-Surg. Thomas Manners to be Assist.-Surg., vice Deakins, who exchanges.—Hospital Staff.—Assist.-Surg. R. T. Deakins, from the 3rd W. I. Reg., to be Assist.-Surg. to the Forces, vice Manners, who exchanges.

Ordnance Medical Department.—Surgeon J. E. Williams to be Senior Surgeon, *vice* Whitelaw, deceased; Assistant Surgeon J. S. Little, to be Surgeon, *vice* Williams; Temporary Assisting Surgeon W. Perry to be Assistant Surgeon, *vice* Little.

Naval Appointments.—Surgeon Charles W. White (1841) to the Phaeton, fifty-gun frigate, at Sheerness; Assist.-Surg. W. Gruggen (1841) to the Phaeton. Robert J. B. Chambers, to be Surgeon to the Castor, at the Cape of Good Hope.

Indian Appointments.—Surgeon J. Boyd appointed Surgeon, *vice* Doig, and posted to the Presidency division. Surgeon R. R. Rooke, to officiate as Superintending Surgeon, in the absence of Superintending Surgeon Streaker, and to be attached to the Southern division. The last-named officer had been posted to the Southern, and Superintending Surgeon Edwards to the Poonah division. Surgeon Hamilton has been confirmed in the medical charge of the marine battalion, *vice* Boyd. Surgeon B. White to be Medical Storekeeper at the Presidency, *vice* Dr. Boyd. Surgeon Bun is to proceed to Sholapore, and take charge of the 3rd cavalry. This last report is doubted.

The Cholera.—A letter from Gray, in the department of the Upper Saone, states that cholera has broken out with extraordinary intensity in that town.

Baths and Washhouses in London.—The Court of the Common Council of the City of London have recently discussed the propriety of erecting baths and washhouses. The utility and profit of such erections were strongly insisted on, and a resolution was adopted, referring the further consideration of the matter to the Improvement Committee. There is, therefore, reason to hope that London will soon be provided with this inestimable benefit to the poorer classes. Cleanliness is next to godliness.

TO CORRESPONDENTS.

We are sorry that the letters referred to by Dr. Inglis escaped our observation. The many newspapers we receive weekly must plead our excuse. If at any time our correspondents desire to draw our attention to a particular article in a paper, we should esteem it a favour if they would, at the same time, write to us on the subject. A disclaimer on our part of the doctrines to which Dr. Inglis refers, is quite unnecessary. To ask a man to declare he is speaking the truth, is to suppose him capable of telling a lie. We are sure Dr. Inglis does not wish to insult us. He must remember, that the only parts of a journal for which an Editor is responsible, and which, consequently, alone speak the policy and the opinions of the journal itself, are the leading articles, reviews of books, and notices to correspondents. For an accurate transcript of the statements made at Societies we are obliged to trust to our reporter. Dr. Inglis would not wish us to leave out any part of such report because it might seem, to a jaundiced eye, to tell for, or against any man or set of men. We beg to assure Dr. Inglis, however, that we shall not forget a certain trashy publication, the organ of lies and quackery. We hope, in the early numbers of our next volume, to expose the folly of the system and the weakness of its supporters, as well as the devices to which some of its unprincipled advocates have had recourse to bolster up its credit. We have for some little while had the idea of undertaking the task, and have no doubt we shall satisfy our correspondent. To be of use to the Profession, the exposure must be full and complete. A tirade against individuals—a calling of hard names never yet overthrew the weakest cause; nay, such a proceeding adds somewhat of weight to the arguments adduced in its favour by those who seek to dupe the ignorant but good-natured of mankind.

Dr. Milroy's obliging communication has been received.

Mr. Yearsley promises us an early paper upon "False Tympana."

"Mr. Braid, Manchester."—We beg to acknowledge the receipt of a letter, and offer our best thanks for the kind suggestions.

"Mr. W. H. Boresham, Haverhill."—The communication "On the application of Creasote to Burns and Chilblains," shall appear as soon as our space will permit.

"Mr. Samuel Gibbons, Congleton, Cheshire," "On the Microscopic structure of Bone and Cartilage," received.

"Mr. A. C. Lee, Southwark."—Received, and not forgotten.

"A Victim of Misplaced Confidence."—The article on Dr. Simpson's Air tractor has been received.

"Four Eyes," says, that the University College miasma is at work again. The under-scullery maid at the Hospital has given warning, in consequence of the kitchen stuff of late getting small by degrees and beautifully less.

We have great pleasure in announcing that we shall publish in an early Number a communication from Professor Graham, "On a New Property of Gases."

"An Assistant."—1. No. 2. Not so much as in England, in consequence of the great competition.

"Dr. George W. Balfour, Cramond."—Communication received.

Mr. Macilwain shall receive a private communication.

"Mr. Thomas Watson, Chatham."—We will endeavour to comply with the suggestion of our correspondent, but many circumstances are constantly occurring which render it almost impossible.

We have received a reprint from the "Morning Chronicle," headed "Gutta Percha and its Uses." We willingly testify to the fact of the great utility of this article, but have not room for the communication sent.

"Non-Medicus."—We know nothing of the person referred to, any further than that he is both a Member of the College and a quack.

"Mr. T. Davis, Tickenham, near Bristol."—Received.

A Correspondent has forwarded to us the following handbill:—"Messrs. Graham and Armstrong beg to inform the inhabitants of the parish of Farlam, and surrounding neighbourhood, that they have engaged Mr. James Lyon, surgeon, a gentleman of experience and ability, as their assistant in the above district. Mr. Lyon will reside at Hall bank-gate, and his charges for attendance on the workmen and their families, will be on the most moderate scale:—The fee for Midwifery cases will be 10s. for cases within a mile of Hall-bank gate; 12s. 6d. for cases above one and under three miles; and 15s. for cases beyond that distance. Messrs. G. and A. hope the workmen will appreciate the great advantage which will result to themselves and families from having a respectable and properly qualified Medical Practitioner residing among them, and trust they will not fail to patronise him according to his merits.—Brampton, Oct. 22nd, 1849." We regret that such means should be followed by members of the Medical Profession to increase their practice.

"Anti-Humbug."—Received.

The desire of completing Mr. Wardrop's Work obliges us to postpone the publication of many valuable papers. Our Correspondents must accept this apology for any delay which may occur.

Mr. Walton's Lectures will be immediately resumed.

Our Article on Public Hygiene is in type.

Dieffenbach's Work will be continued in an early Number.

"Anti Quack."—In the Act of the 44th of George III., regulating the stamp duties on patent medicines, the City of Edinburgh was not inserted in the column entitled "Scotland;" an amendment to the Act passed in 1812, however, has remedied the defect, and persons in the Scottish capital selling patent medicines, must now take out a license annually, for which they have to pay £2.

"J. L., Birmingham."—"Will Cantharides act as a poison when applied to a wound?" Yes; it has been also known to produce death when applied over a large surface of the body without abrasion of the cuticle.

ORIGINAL LECTURES.

CLINICAL LECTURE ON SOME DISEASES OF THE TESTIS.(a) DELIVERED AT UNIVERSITY COLLEGE HOSPITAL,

By R. QUAIN, F.R.S.,
Professor of Clinical Surgery in University College, and Surgeon to University College Hospital.

[Reported by EDMUND CARVER, M.R.C.S., lately House Surgeon to the Hospital.]

(Continued from page 469.)

SYPHILITIC DISEASE OF THE TESTIS.

A case which is now under treatment among the out-patients, may be usefully placed in juxta-position with the foregoing. The history is briefly this:—

William S——, aged 71, applied 5th February last. He states, that in the preceding March, eleven months before, venereal sores appeared on the penis, for the cure of which, after neglecting to adopt any treatment during six weeks, he took mercury under the direction of a medical gentleman, and was fully salivated. After two months' treatment he was considered to be cured. Subsequently, however, an eruption appeared on the skin, and it was accompanied with sore throat. He now took pills again, and his mouth became a second time very sore.

When this patient came to the hospital, the remains of an eruption, apparently a papular syphilitic one, were distinguishable on his face. Both his eyes were affected with conjunctival inflammation, and the right one with also well marked iritis. The sight of this eye was so dim that only the light could be distinguished with it. The disease yielded steadily to the use of calomel and opium in small doses, administered after some blood had been taken from the temple by means of cupping glasses. He was dismissed cured in March.

In September following, the right testis became swollen and painful, and the enlargement went on very rapidly, the body of the gland and the epididymis being both involved.

In October, while the swelling on the right side was fast subsiding, the left testis became enlarged, but without pain or other indication of any degree of inflammatory action.

Both the glands have improved steadily under the use of mild mercurial medicine, in the form of blue pill, combined with iodide of potassium and sarsaparilla.

Now, what was the exciting cause of this disease? When the right testis became swollen, the redness of the scrotum, the tenderness and the rapid swelling corresponded exactly with a mild attack of inflammation of the gland which arises from gonorrhœa. There was, however, no disease of the urethra; and, no local cause of any kind being discoverable, we had to turn to the disease which had lately been, if it were not still, in a degree, pervading the system. Here the question arises, whether the enlargement of the testes may fairly be numbered among the sequelæ of syphilis? The number of cases in which these organs are affected, in comparison with the number of persons who suffer from syphilitic disease, is so small, that it is not easy to determine whether the morbid condition of the glands be accidental or the direct consequence of the specific disease. Writers upon the subject, however, invariably, I believe, place the testes among the organs which are liable to be involved in the disease in question. In a practical point of view the question is of little importance, because there is no appreciable difference between the enlargement of the gland arising in such circumstances, and that which occurs in a person entirely free from every trace of venereal disease; and, moreover, the most successful treatment of the one and the other is the same, viz., the use of a mercurial preparation, except where the administration of this medicine is contra indicated by the condition of the patient's health.

SCROFULOUS DISEASE AND CHOLESTEOTOMA.

The third case differs altogether from those already noticed; and it presents some points of peculiar interest.

Joseph C., aged 30; admitted Feb. 16; married; a fishmonger by trade; native of London. He is of spare habit of body, of fair complexion, with very thin, delicate skin; but has never had any enlargement of the lymphatic glands about the neck or elsewhere. Had gonorrhœa eleven years ago. States that his father died of erysipelas and scrofula.

It appears that, about a year and a half ago, matter formed in the right testis, and the abscess was opened after the lapse of three months. He then slowly recovered; but some swelling still remained where the abscess had formed. Subsequently, he suffered much from pain, especially about the hips and back, and a swelling again appeared at the lower part of the scrotum. This, likewise, was opened, and matter was evacuated.

At present, this patient's health is much impaired from continued pain and discharge of matter, though this is but in small quantity. The pain darts from the right testis, along the groin, and down to the back of the leg. When he moves, he suffers from pain in the lumbar region. There is slight tenderness on pressure, over the gluteal region, more particularly on the right side. His chief suffering is occasioned by the pain in this part.

The right testis is enlarged to about the size of a hen's egg, and it is firm and hard to the feel. The epididymis is indurated, and the cord is somewhat thickened. There has for some time been occasional difficulty in passing water, and there has also been a slight puriform discharge from the urethra. By means of bougie No 7, a stricture was discovered; but the instrument was passed with little obstruction. The scrotum, at its lower end and on the right side, is indurated, and a thin discharge issues through a small ulcerated opening. Higher up, the scrotum is adherent to the testis. With the upper end of the epididymis of the left side is connected a small cartilaginous or fibro-cartilaginous nodule, larger than a pea. When this body is pressed, the same kind of pain is felt over the left side of the pelvis (the gluteal region) as that noticed on the right side. It is, however, less severe, and does not extend to the thigh.

Observations.—In our inquiry into the nature of this case, we proceed directly to the testis and the epididymis, the outline of both these parts being at once distinguishable by the touch. If the tunica vaginalis contained fluid (the usual product of disease affecting it) in any quantity, the gland and its appendage would be shut out as it were from examination. The testis itself is said to be enlarged, while the epididymis is indurated as well as augmented in size; but, considering the length of time the morbid condition has existed (a year and a half), the alteration of the size is not considerable. In the same space of time, either of the two diseases mentioned in a former part of the lecture, namely, the "chronic enlargement" and the "encephaloid disease," which, apart from the acute inflammation arising in connexion with gonorrhœa, are the diseases most frequently met with in the organ, would have attained a much greater size, and would have altered the gland in a greater degree. Passing away, then, from any more detailed reference to those diseases, I may state at once that the history of the case corresponds in many respects with that of the scrofulous deposit in the testis. The epididymis was first and chiefly affected: a small abscess formed in that part, and was discharged through an ulcerated opening in the skin. One such abscess being healed, another and another formed, and followed the same course. The progress of the morbid action has thus been altogether very slow. Such is in fact the general course of events in scrofulous disease. And with the progress and character of the local disorder must be associated the general condition and appearance of the patient, which were those of a person likely to suffer from scrofulous or tuberculous disease.

In the treatment, the first objects sought to be attained were the improvement of the patient's general condition and the enlargement of the urethra. With a view to the former of these objects, he took at different times, besides being allowed a nutritious diet, liquor. potassæ, quinine, and a preparation of steel. Under this treatment the health was decidedly ameliorated, at the same time that the condition of the urethra was much improved by the use of bougies. Still the disease in the scrotum and the pain over the hip and along the thigh continued, with little or no abatement. In order now to decide upon the course to be adopted, with a view to afford permanent relief, we must inquire if there be any connexion between the actual diseases, as well as between these and the great source of the patient's suffering. And first: Did the condition of the urethra give rise to the disease of the testis? To this I would answer, that the kind of this disease was not that which results from stricture of the urinary canal; and, at all events, it has been seen, that the restoration of the urethra to a healthy state was not attended with corresponding amelioration of the disorder in the scrotum.

Again, What is the cause of the extreme pain in the limb? The following facts bear upon the question:—Where the pain was most sensibly felt there was no disease; and the pain was not generally augmented by pressure. It was accidentally found, that pain of the same kind, and in a corresponding situation, though less severe and less extensive, was produced upon the left side by compressing the small fibro-cartilaginous body connected with the epididymis of that side. Again, in most cases of hernia humoralis, pain is felt beneath the ribs, and even upon the hip; but the suffering from this cause is usually not considerable, at least when compared with that experienced by our present patient. Still I have observed even more severe. I have just now under my care a gentleman suffering from that complication of gonorrhœa, in whom the pain has extended over the loins, the pelvis, the thigh, and along the leg, even to the great toe; and it has been on two occasions so acute, (first from one testis being inflamed, and then the other,) that fits of what might be named hysterical sobbing have come on in consequence of the severity of the suffering. This patient is a person of very nervous temperament, and he is so by inheritance. He was, it may be mentioned, completely relieved of each neuralgic attack by a dose of liquor opii sedativus. These considerations lead us to the conclusion, that the diseased condition of the testis and scrotum was the original cause of the pain on the posterior aspect of the limb, the nervous connexions serving in this, as in some other cases, to explain the phenomenon.

As to the treatment: if the patient had been able to follow, his occupations without much suffering, (as it generally happens with a like amount of apparent disease,) I would have advised only a tonic and palliative plan of treatment, in the expectation that in this, as in other similar instances, the local disease would subside, leaving the testis, very probably, in a state of atrophy. But the poor man had already endured great pain for a protracted period, being thereby debarred from supporting himself or his family, and it was not possible t afford him a well grounded assurance, that, by following any plan of remedial treatment, his suffering would soon terminate. He desired, then, that the testis should be removed, and I thought its removal the wisest course for him.

After the operation the wound quickly healed, and the patient speedily left the Hospital much improved in every way, and entirely free from pain.

Examination of the Testis.—It is larger, and somewhat firmer than natural. A longitudinal section being made, it is found that the rete testis and the greater part of the epididymis (all except its globus minor) are wanting. The place of the seminal tubes that belong to these parts is occupied with dense fibro-cellular substance; and in this structure are two detached masses of soft opaque yellow matter, to all appearance scrofulous. The skin of the scrotum is firmly adherent over this part.

The body of the gland and the small remaining part of the epididymis are thickly studded throughout with minute rounded bodies which are white, opaque, and may be said to be pearly in appearance

These corpuscles resemble particles of very clear white wax or spermaceti, but they are not brittle like the latter substance. They separate entire from the seminal tubes.

From the statement respecting the testis and its appendage, it is obvious that the restoration of the organ to a healthy state was impossible, the glandular structure being wholly separated from the excretory duct.

The morbid deposit, which in the upper part of the epididymis was probably associated with the scrofulous disease, but was elsewhere independent of it, seems to correspond with the description of a substance well described by Professor Cruveilhier (" *Anatomie Pathologique,*" livr. II. and V.) and Professor Müller (" *On Cancer,*" *translated by Dr. West*, p. 155), and named by the latter observer cholesteotoma. It is a peculiar fatty matter; and, when chemically examined, has been found to consist of cholesterine and stearine. Under the microscope, with a high power, it is seen to be composed of irregular cells.

The preparation before you and the drawings, which were made for me under the kind superintendence of Mr. Quecket, illustrate the facts I have enumerated. One of the drawings represents cells filled with granular matter—magnified 400 diameters. A portion of a healthy seminal tube, and another piece enlarged in consequence of proximity to the disease, are delineated in these two figures, both being magnified 170 diameters.

Cholesteotoma has been met with in masses of of various sizes (some very large) and in many parts of the body, but most frequently in the brain. It has been found associated with other diseased formations, even with cancer; but it is not at all a malignant substance, seeming to act injuriously on the organ in which it is deposited, only by its mass. The corpuscles, in the case before us, caused by their pressure a varicose condition of the seminal tubes. In time, and by its increase, the deposit would probably have led to the entire absorption of the gland.—For a succinct account of all that has been hitherto ascertained about this substance, see Dr. Walshe's Essay, entitled, "Products (Adventitious,)" in Dr. Todd's "Cyclopædia of Anatomy and Physiology," Vol. III., p. 98.

After he left the Hospital, this patient had a return of the old pain upon the pelvis and the thigh, but I have ascertained that, in consequence of some imprudence, the cicatrix had re opened at the time and had assumed a somewhat angry appearance.

More recently (October 27) he has come to the Hospital to be examined, and the following report has been taken. Now nine months since the operation was performed, the wound is firmly cicatrised, and there is no pain whatever about the scrotum. But he states, that when the weather is warm the pain from which he formerly suffered becomes troublesome, though he is quite free from it while the temperature is cool. The uneasy feeling is not in the slightest degree augmented by pressure of any kind, whether light or hard. The urethra admits the bougies Nos. 9 and 10 easily. The kidneys and the urinary bladder give no indication of disease. He is ordered to take a preparation of steel continuously and in gradually augmented doses.

Nov. 27.—To day the patient reports that he has experienced much relief from pain, insomuch that he has been able to walk a long distance without inconvenience, since he has taken medicine prescribed ten days ago, viz., ferri sesqui-oxidi, ʒss in treacle three times daily. And he adds, that being without the medicine for two days, while in the country, there was a recurrence of his suffering during that time.—The dose to be augmented.

The first return of the pain over the pelvis seems to be attributable, in conformity with the facts and reasoning in a previous part of the lecture, to the condition of the cicatrix at the time. But how are we to explain the recurrence of it, which is said by the patient to have been owing to changes of temperature, seeing that the scrotum is firmly healed, and that no irritation or uneasiness is present in this part? It may be that the physical alteration, which though inappreciable to our senses, probably accompanies the long-continued presence of pain in a part, is re-excited under the influence of atmospheric changes acting upon a person of feeble constitution. Be this, however, as it may, there is every probability that our patient is now about to be permanently relieved of his suffering, for the preparation of steel (a medicine which, before the operation, failed to afford him any relief) has speedily produced a very beneficial effect.

ORIGINAL CONTRIBUTIONS.

CASE OF POPLITEAL ANEURISM CURED BY COMPRESSION.

By HENRY THOMPSON, M D., Surgeon to the Tyrone Infirmary.

John Hughes, aged 30, unmarried, of florid, healthy appearance, though somewhat emaciated, hitherto free from disease, with the exception of primary symptoms of syphilis, which left a cicatrix in the right groin, and for which he had been successfully treated with mercury about three years before, was admitted into the Tyrone Infirmary on the 22nd of September, 1849. His occupation was that of a canal boatman; in the exercise of which he was subject to violent exertions of the lower limbs in tracking boats, carrying heavy burthens, and leaping across wide drains. He had just travelled a distance of twenty-one miles on a cart, and was suffering great pain and distress from a tumour, which filled the right popliteal space, and extended downwards into the upper third of the calf of the leg, increasing the circumference of the limb, at the tubercle of the tibia, to the extent of 4½ inches beyond that of the opposite side, the measurements being—round tubercle, 15¼ inches; an inch lower down, the largest part, 15¾ inches. The tumour was of a somewhat globular form and regular outline, not clearly defined to the eye, in consequence of the swelling and congestion of the leg which accompanied it; but its limits easily ascertained by the touch, from its tense and elastic firmness and the bursting sensation, caused by a diastolic pulsation, communicated by each throb of the heart to every point of its surface. This pulsation, accompanied by a rushing bellows murmur, was easily commanded, but without any diminution in the size of the tumour. The appearance of the integuments did not differ from that of the rest of the limb, except in one spot, corresponding to the centre of the popliteal space, where, to the extent of a penny, an evident elevation, a distinct softness, a dusky redness, and a tenderness, indicated this as the position in which the opening was to be expected, and in which the process of thinning had already made considerable progress. The knee was flexed to a right angle, and could not be extended in the least. The foot was swollen to nearly double its natural thickness, but did not pit. The cutaneous veins of the leg were full, the integuments of purplish red shade, the whole leg hotter than natural, and swollen so as to be an inch thicker than the other immediately above the ankle, the superficial glands in the groin enlarged and tender. He complained of a numbness of feeling, with a tingling sensation in the foot and outside of the leg. He had just taken a glass of spirits, and his face was flushed, skin hot, pulse 120, tongue foul, bowels confined.

About four months ago he first perceived a small swelling, which he describes as "a welt with a beating in it" running across his ham. It was preceded by some feeling of numbness and weakness in the limb, which obliged him to confine himself to the boat, and give up walking about. Two months ago, in consequence of the increase of the swelling, he became unable to extend the limb, and was forced to confine himself to bed until he was seen by a Medical man, who advised him to go into hospital to have the operation performed. He presented no symptom of any other lesion of the circulating system.

He was placed in bed, with a pillow supporting the outside of the limb. Ordered low diet and the following medicine:—

℞ Hyd. submur. v. gr.; pulv. jal. c. ʒss.; ditto, zingib. gr. i. in pulv. statim sumend.; and after about two hours, when he had become somewhat tranquillised, one of Read's thigh clamps was so applied as to command the pulsation in the tumour. It returned, however, after about half an hour, and it was found impossible, from the pain and distress it occasioned, to continue it longer than three hours, when it was removed, and a wet cloth laid over the limb.

23rd.—Had some sleep, and feels somewhat easier; bowels freely opened. The pressure was again attempted, but caused such pain at the point of pressure, starting of the limb, and venous congestion, that it was not kept up for more than three hours, and that very imperfectly; but still so as to moderate very considerably the pulsation.

24th.—Suffered a great deal of pain in the tumour last night, with increased numbness in the leg and foot, the swelling of which is also increased; it now pits on pressure; pulsation in tumour as vigorous as ever; face flushed, and skin hot; pulse 100, full and strong Venesectio ad ℥xvi.

A quarter grain tartar emetic in solution every third hour; pressure discontinued.

Evening.—Nauseated all day; limb much easier.

25.—I had pressure kept up for six hours last night by relays of assistants using their fingers; but even this he could not bear on the same point for more than half an hour at a time, and described the pain it occasioned as even less supportable than the clamp. Size of tumour rather increased, pulsation undiminished, and appearance of pointing in the ham decidedly more evident. Discouraged by the apparent impracticability of persevering in the pressure, I made up my mind to tie the artery, and was actually about to proceed to the operation, when closely examining the foot, which presented a livid blush over the ball of the great toe and inside of instep, I perceived that these parts had lost their sensibility, and the cuticle had a loosened, shrivelled look, as if just about to vesicate. A thermometer, held between the toes, indicated a temperature four degrees above that of the opposite side. Regarding these symptoms as conclusive indications against the ligature. I represented to the man, that amputation would be a preferable proceeding, to this he reluctantly agreed; but as there was no immediate necessity for this last alternative, I continued the tartar emetic and the cold application, and added ten drops of Battley's sedative at night.

26th.—He passed a good night, quite free from pain, and I found the limb much improved; swelling and congestion less; pulse 84; bowels confined. Stopped tartar emetic. Ordered haust. misturæ purgantis; continue cold application to limb.

27th.—Appearances unchanged; strong pulsation in tumour; feels no pain, except femoral artery is compressed, when the burning feeling in the foot becomes insupportable. I found, however, that by changing the compressing force to a point immediately below Poupart's ligament, this pain was rendered so much less that he could bear it. I therefore arranged a clamp in such a manner, that it kept up a degree of compression upon this point sufficient to arrest the circulation in the tumour. I commenced this at half-past nine, a.m., placing a pupil to watch and screw down the pad whenever pulsation should return. The enlarged glands in the groin greatly interfere with the application of the pressure in this situation. However, by slightly varying the point it was kept up, though very imperfectly, the pulsation never entirely absent for more than three quarters of an hour at a time, until six p.m., when the clamps were removed for the night. At the commencement of the pressure this morning he got a draught containing ten drops of Battley's sedative, and is taking the following mixture:—

℞ Tincturæ digitalis, ʒi.; aquæ lauro cerasi, ʒiij.; mist. camphoræ, ℥vss.; cap. ℥i. Quaque tertia horâ.

At nine p.m. had another draught of ten drops of Battley's sedative.

28th.—Very easy night; quite free from pain; pulsation as strong, as diastolic, and as superficial as ever, particularly posteriorly, where, however,

the appearance of pointing is not increased. The congestion of the limb caused by the pressure yesterday has entirely subsided, leaving the original œdema as before. There is a diminution in the circumference of the tumour to the extent of three-eighths of an inch. He is tranquil and easy. Pulse 90; face still florid, and circulation vigorous. Read's pelvic clamp was fitted better to-day, a pad of chamois leather having been placed over the vessel as it crosses the ramus of the pubis, and the compressing force made to bear accurately and perpendicularly on it, so as completely to command the pulsation. The congested appearance of the limb immediately ensued, but he felt much less uneasiness from the pressure. An anastomosing branch as large as the temporal has made its appearance along the inside of the knee, pulsating strongly whenever the pressure is removed.

10 p.m.—The pressure has been kept up with little intermission for the last twelve hours, varying the point to the extent of about two inches, by means of a second clamp placed lower down on the limb, and latterly by merely changing the moveable arm of the pelvic one. The pulsation returns generally at the end of each hour or so, and requires some change to get it under control again; but it is now evidently becoming feebler, less diastolic, and commanded by a much slighter force; the man bears it better, too, and only complains of the point pressed, no longer of the foot and leg, which, though much swollen, are less congested, and have recovered their natural sensibility, but lose their heat during compression to the extent of about four degrees. The patient is in good spirits, and does all he can to assist the treatment. The Digitalis mixture is continued, with a sedative draught at night.

11½ p.m.—The pressure of the apparatus became so painful, that I removed it, and found the force of the pulsation much lessened, and its diastolic character gone, except between two points, the centre of the ham, and a little below the head of the fibula; in every other part it had ceased.

Sept. 29th.—Had a good night; tumour more solid. The pulsations which remains can scarcely be called diastolic, and is so defined and linear, that it is quite doubtful if it be not in two anastomosing vessels. No bruit now; dimensions of tumour unaltered. Clamps re-applied.

Sept. 30th, 1 a.m.—The compression was kept up with little intermission the whole of yesterday, and the pulsation perfectly commanded, except for a few seconds, during the changing of the pads, which was necessary, at intervals of from three quarters of an hour to an hour and a half. Pulse 70; small and feeble; spirits good. Finding him much fatigued, I removed the apparatus, and found the pulsation very feeble, and confined to a line in the centre of the ham, where the appearance of pointing had been most manifest.

Haust. Lq. opii sed. gtt. xxv. Misturæ purgantis, ℨij., sum. mane.

Half-past 10 a.m.—A remote and indistinct return of pulsation on the outside, that posteriorly somewhat stronger and over a larger space. Pressure re-applied.

October 1st.—The pressure was discontinued at four p.m., yesterday. The pulsation, which remains posteriorly and on the outside, assumes more and more the character of an enlarging vessel. Tumour becoming more circumscribed by the subsidence of the surrounding œdema; now feels very solid, has had no pain in it latterly. Pressure discontinued altogether.

Evening.—Since the middle of the day he perceived a considerable increase in the temperature of ... is entirely gone; sensibility perfect; considerable œdema remains. Anastomosing vessels round knee perceptibly enlarging, so that the pulsation of one which follows the course of saphenus nerve is quite visible, and the femoral cannot be traced beyond the origin of this branch about the opening in the triceps. Neither of the tibial arteries can be felt, though remarkably large, and easily detected in the opposite limb; œdema of limb much diminished, and boundaries of tumour becoming very defined; it feels solid, and quite free from pulsation. He is perfectly tranquil, free from any uneasiness, and can now extend the leg to an angle of 45. Pulse 72. Applied a bandage from toes up lightly, compressing the limb and tumour. Omit digitalis mixture.

Oct. 3rd.—All going on well; circumference round turbercle of tibia 14¼; round largest part 14¾; œdema of foot much less. Ordered 12oz. of bread, a pint of milk, and a pint of tea in the day. He has been on low diet; half a pound of bread, and a quart of whey, until to-day.

5th.—Round tubercle 14; below 14½; bandage continued.

7th.—Bandage caused pain from its tightness; no change in measurements. Omit bandage; friction, with soap liniment.

11th.—Round tubercle 13¾, below 14. Can extend the limb so as to touch the ground with his toes; when he stands erect all œdema gone, except about heel and toes. He has been up these two days, moving about on a crutch, the limb firmly bandaged. General health excellent; allowed full diet.

20th.—No change in dimensions of tumour; can extend the limb so as to put the heel within an inch of the ground when he stands erect. No pulsation, but a remote and indistinct click is heard, synchronous with the pulse, on applying the stethoscope posteriorly. I re-applied the clamp, and kept up the pressure tolerably perfectly for twelve hours.

21st.—Applied a tight bandage after friction, with turpentine liniment.

Nov. 10th.—Has been using the liniment ever since; now walks about without much lameness, extending the limb completely; there is still, however, considerable enlargement at the upper part of the calf of the leg, beneath the femoral origins of the gastrocnemius. The tumour has greatly diminished in its vertical diameter, though not much in its circumference. Pulsation in anastomosing vessels much less evident than when they first began to enlarge.

14th.—Circumference round tubercle 13 in., an inch lower, 13½; tumour gradually but steadily diminishing; no return of pulsation in tibial arteries; use of limb becoming more perfect every day.

Tyrone Infirmary, Nov. 11, 1849.

[We congratulate our Correspondent on the result of this interesting case,—an additional unit to the list made out by his countryman, Dr. Bellingham. We would have used the *double* clamp, perhaps, from the beginning—gradually, but steadily. We have seen the best effects from it. And, towards the latter end of the case, electricity has proved a valuable adjunct. The case is in every way worthy of Dr. Thompson's skill and assiduity.—Ed.]

HOSPITAL REPORTS.

KING'S COLLEGE HOSPITAL.

The most interesting class of tumours the Surgeon has to deal with are those situated in the region of the neck. A formidable looking growth of thirty years' standing, was removed by Mr. Fergusson from the region of the parotid gland, on Saturday last. The morbid mass was seated on the right side, and was firmly adherent to the fascia, in consequence of inflammatory action, which had of late been going on, accompanied with much pain. The patient had obstinately refused any attempt for its removal, as until lately he had suffered no material inconvenience from it; but latterly he had urgently wished an operation, as he felt so much pain in the tumour. The mass extended considerably over the face, and involved the textures behind the neck of the jaw, and, although it was free and moveable in the former direction, its connexions appeared to be firm, and deeply seated behind.

Mr. Fergusson commenced the operation by making an incision about an inch and a half from the corner of the mouth, continuing it across the tumour to the outer side of the sterno-mastoid muscle. This was crossed by another cut, commencing just below the ear, and carried downwards over the mass. The flaps of skin were then cautiously dissected back, particularly over the posterior part of the tumour. And after some careful manipulation the whole of the mass was removed. The bleeding was by no means extensive; seven small vessels required a ligature.

Mr. Fergusson endeavoured to avoid dividing the portio dura, but, from the appearance of the patient before he left the theatre, he considered it doubtful as to whether he had not done so. The flaps were stitched together, and a compress of lint, and a bandage was applied.

On a section of the tumour it was found to consist partly of a fibro-gelatinous tissue, partly of a cerebriform nature, and in the upper portion of it was a cyst.

Mr. Fergusson was of opinion, that the tumour was originally of a non-malignant nature, but that it might latterly have degenerated into a malignant growth. He should have it thoroughly examined, and would report to the students the result of such examination.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

TREATMENT OF HYDROCEPHALUS.

Every one is acquainted with the difficulty of finding any effectual treatment for this disease, especially for that most dangerous form known as "tubercular meningitis." M. Hahn, physician to the hospital at Aix, recommends strongly the following method, in cases where the disease has already made some progress before the medical attendant has been called in. Dr. Hahn's method consists in employing tartar emetic ointment in friction on the scalp, which is previously shaved. The ointment is rubbed in for ten minutes at a time, and a piece of linen besmeared with it is then placed on the head. The frictions are renewed every two hours, until the pustules begin to appear. The effects are, of course, very severe. The whole scalp becomes inflamed, and numerous small ulcers are formed, which heal with difficulty, and generally destroy the points of the scalp in which they were situate. The author affirms that he has employed this severe, but absolutely necessary mode of treatment, with success for the last twenty years, having thereby saved more than a dozen children, whose lives would have been inevitably sacrificed but for it.

GUTTA PERCHA BOUGIES.

From some cases published in the *Medical Gazette*, it would appear that the use of these bougies has been followed at St. George's Hospital by unpleasant consequences, the bougies having unrolled and a portion remained in the bladder. M. Civiale, in a short conversation on this subject, mentioned to me that the accident probably depended on the manner in which the gutta percha bougies are manufactured in England. They are made by rolling a band or strip of the substance round a stylet, and then applying heat. Hence, they are subject to unroll. In France, the line of puncture runs along the whole length of the bougie, and accidents of the kind mentioned by Mr. Hawkins never occur. M. Civiale states also, that, so far from having observed any irritation produced by the contact of gutta purcha bougies with the mucous membrane, he has found that they remain in the urethra a much longer time without inconvenience than those of Indian rubber.

PRESERVATION OF LEECHES.

The increasing price of leeches, and the great difficulty of procuring them, almost at any price, render it a matter of great importance to discover the best method of preserving them. Leeches kept in the ordinary manner secrete a quantity of gelatinous matter, which becomes attached to their bodies, and soon kills them. M. Dominé has observed that nothing enables leeches better to get rid of this gelatinous matter than moss. This must be selected as green as possible, washed and perfectly cleaned, then placed in a bottle (a quart one for 100 leeches). During the heat of summer it will

be well to place a little water in the bottle. During winter they need not be changed often; but in summer the moss must be changed every second day, and the leeches kept in a cool cellar. Following these simple rules, M. Dominé has been able to preserve his leeches in perfect vigour, and with very moderate loss, considering the numbers preserved.

CONTRACTION CURED BY VAPOUR.

A curious case of this kind occurred a short time back at the Hôtel Dieu, in the practice of M. Jobert. Worthy of notice, rather from the simplicity of the means employed to relieve, than from the nature or symptoms of the malady. A young girl had pricked the palm of the hand with a needle. Soon after this slight accident contraction of the flexor muscles set in, and after three months had arrived at such a pitch, that the nails seemed as if they would be driven through the skin. Almost every imaginable remedy had been tried without success, when M. Jobert thought of trying the effects of a vapour douche. The first application gave relief, and after the second one, the power of extension was so complete, that the patient appeared to be completely cured.

CHOLERA HONOURS.

M. Louis Lucien Bonaparte, cousin of the President, has received the decoration of the Legion of Honour, "for the services which he has rendered to practical chemistry during his long exile; for his experiments and publications; for his persevering efforts to make France loved and respected in Italy, by publishing in that country the discoveries of the French school." So the Gazette informs us, obeying a wise law recently enacted, to the effect, "that the titles to the honour of decoration shall be published with each appointment." To the Medical Profession M. Louis Lucien Bonaparte is favourably known as the discoverer of the valerianate of zinc, and many other pharmaceutical improvements.

SCOTLAND.

[From our Edinburgh Correspondent.]

The second meeting of the Edinburgh Medico-Chirurgical Society took place on Wednesday, December 5th, Mr. Syme, the President, in the chair.

Dr. Andrew read an account of a singular case, which had been partly under his care, partly under that of Dr. William Robertson, in the Royal Infirmary last autumn. The patient was a soldier's wife, who had been for a few days under treatment in Edinburgh Castle, before being brought to the Infirmary. The chief symptoms had the appearance of being referrible to malignant disease of the pelvis, there being at the same time some indications, though by no means unequivocal, of the existence of pregnancy. From the first there was considerable swelling of the right labium, and enlargement of the left side of the abdomen, latterly reaching as high as the left hypochondrium. The os uteri could not be detected. There was a distinct areola round the nipple, but the mammæ were flaccid. The stethoscope discovered what seemed a placental bruit, but no sound like that of the fœtal heart could be made out. When one hand was applied to the right side, and the other previously made cold was placed over the swelling on the left side, motions were imparted to the hand like those of a living fœtus. After the patient had been some time in the Infirmary, a fluctuating tumor was felt through the parietes of the vagina, which it was proposed to evacuate, but the rapid failure of her strength prevented this proceeding. During the six weeks she was in the Infirmary before her death, various changes took place, but nothing occurred to elucidate the real nature of the case. Just before death her strength was wholly exhausted, the emaciation was extreme, the abdomen was enlarged to a degree beyond what occurs in women before delivery at the full time, the tumour encroached on the right femoral region, and the right lower extremity was much enlarged as compared with the left.

Even the dissection left some points of the case in obscurity. The external surface of the abdomen presented the wrinkled appearance belonging to women who have born children. The head was not examined. The organs in the thorax were healthy. When the abdomen was opened, the bowels were found pushed very much upwards; its lower part and the whole pelvis were quite filled, there being on the right side a large tumour, and the left being occupied by the distended uterus. The tumour on the right side pushed the peritonæum upwards and forwards, extending in the vertical direction to the kidney. The contents of the tumour were bloody coagula and a dark grumous fluid. While in the attempt to remove it entire, it burst. In its structure there was an appearance of imperfect cells. Portions of the fluid subjected to the microscope showed blood-corpuscles in various conditions. On the right side,—that is, on the same side with the tumour,—the bones, entering into the sacro-iliac synchondrosis, were separated to such an extent as to admit between them the extremity of a finger, the only union preserved between them being by a few connecting bands. The adjacent large blood-vessels were entire and normal. It had been remarked during life that the subcutaneous veins on the right side of the trunk were much developed. The uterus was pushed over to the left side, and, on being opened, was found to contain a fœtus of the sixth month, with the cuticle desquamating. There was no liquor amnii; and, as the nurse some days before the woman's death had reported that her bed had become wet, it was concluded that the membranes had given way at that time.

The husband was present at the *post-mortem* examination, and, on being questioned if his wife had been recently exposed to any violence, he said that, about a month before she began to complain, (that is, nearly three months before her death,) she had been accidentally squeezed so violently by a door being shut upon her, as she was carrying some clothes into a room, that she fainted. This led to a belief that the separation of the bones might be a species of fracture in which the bloody tumour might have originated. But many difficulties interfere with this view of the case. In the short discussion which followed the reading of the paper, Mr. Syme expressed himself decidedly opposed to the idea of the separation of the bones being of the nature of fracture.

Dr. William Gairdner then read an account of a case of sudden death from aneurism of the superior mesenteric artery. The case was that of a female who died suddenly in the street, her body being brought to the Infirmary. On dissection, the chest was found generally sound, the left ventricle being strongly contracted, and the aorta being small in the chest,—as also in the abdomen. In the cavity of the peritonæum clots of blood were found to the amount of two pounds and a half; in the peritonæum, between the pancreas and duodenum, there was a ragged opening; and, on further examination, an aneurism of the superior mesenteric artery was discovered, from which a probe passed into the aperture in the peritonæum. Close to the aneurism, on its right side, lay the biliary ducts. The upper surface of the liver adhered to the diaphragm. The stomach was quite free from disease; but, on the mucous surface of the duodenum, was observed an imperfectly cicatrised ulcer, from which could be squeezed a few drops of blood, manifestly derived from the aneurism.

The body was recognised as that of a female servant, 26 or 27 years of age, who had been twice in the Infirmary within the last two years. In the beginning of 1848 she had been there about a month under the care of Dr. Halliday Douglas, on account of hematemesis, accompanied with pain of the epigastrium and jaundice. A short time before admission she had begun to vomit blood in considerable quantities—generally after meals—and sometimes watery fluid was discharged; and, for some time after she was received into the Infirmary, the vomiting of blood continued. On careful examination, no sign of abdominal disease could be detected beyond some degree of resistance below the situation of the liver, and a defect of the usual resonance in the same region. The case was managed on a simple plan, by a regulated diet and mild treatment, on the idea that the hæmorrhage might depend on ulcer of the stomach. At the end of a month, as the symptoms had subsided, she was allowed to go out. Some time after this she was treated in the surgical quarter of the Infirmary for a weak ulcer of the leg, but her former complaints do not appear to have attracted attention on this occasion.

Dr. Gairdner entered, at some length, on the connexion between the history of the case and the *post-mortem* appearances, and there seemed no reason to doubt that the original hematemesis had depended on the communication of the ulcer in the duodenum with the aneurism, and that the jaundice which had accompanied the vomiting of blood had arisen from the proximity of the biliary ducts to the aneurismal tumour.

An interesting conversation then ensued regarding cases illustrative of the long periods during which patients may sometimes live after hæmorrhage has commenced from an aneurism, and Mr. Dick, Lecturer on Veterinary Medicine, who was present, showed some remarkable preparations proving the frequency in the lower animals of abdominal aneurisms, connected in particular with the existence of the worms termed strongyli, as in the horse and ass.

IRELAND.

[From our Dublin Correspondent.]

The opening of the new Colleges, with their chances of success, has been the chief theme of conversation in Dublin for some time. At the Surgical Society, some highly interesting matters have been brought under discussion, while at the schools, the Professors are trying to console one another as best they may, for the late diversion *not* in their favour in the provinces. Some of the medical favourites at the Vice Regal Lodge have been "starring" it in the south and west; but, on the whole, the medical faculties have come out with considerable *éclât*. Within the walls of the old University nothing very novel presents itself, the ancient mysteries are still unriddled in the dubious vicinity of Park-street, while in the hospitals there is a fair sprinkling of ambitious-looking students, and the old never-ending cases and case-takers. The Belfast College opens on the 20th.

The Surgical Society opened its long looked-for sittings on the 17th ult., with an excellent address from Mr. Ellis,—an *eloge* on the late much-lamented Richard Carmichael, to whom the Profession in Ireland is so deeply indebted, and whose name is so favourably known also in the sister kingdom, as one of the most persevering innovators on the old and barbarous custom of salivation in syphilis. Few men have been so respected, both in and out of the Profession, and perhaps since the time of Sir Patrick Dun, who was President of the College in 1693, not many have been so munificent.

After the address, which was most cordially received, Mr. Banon read a paper on the cure of Popliteal Aneurism by Pressure, and furnished the details of a highly interesting case. (a) Mr. Bellingham spoke of some failures which took place in England, from allowing the apparatus to be interfered with. Mr. Adams, whose experience has been so extensive, recommended the new mode of proceeding in the strongest terms; the general sense of the Society going with the latter speaker. Much stress was laid on proper attention to *keeping up the pressure*—the only thing, indeed, needed to effect the cure.

At a subsequent meeting of this Society, the subject of the adulteration of drugs was brought under notice; and, among other things, a specimen of ordinary *Flor. sulphuris* produced, which was shown to contain 47 per cent. of sulphate of lime! It was mentioned, also, that our ordinary Muriatic acid now contains Arsenic. The sources of these impurities are, of course, quite obvious. We should not be the less on our guard; indeed, practical subjects of this kind are, perhaps, too often neglected for matters of mere theoretic interest. Dr. Bellingham related three cases of a somewhat

(a) We feel pleasure in adding another case to Mr Banon's in our present Number.—Ed. *Medical Times*.

rare injury—rupture of the long head of the Biceps—the subjects of external injury. The appearance of each of the patients was distinct and peculiar; each supported the elbow with the opposite hand, felt total powerlessness of the arm, pain on motion, pain along the biceps, pain on separating the arm from the side. Mr. Key, at the opposite side of the Channel, was, perhaps, the first that told us the reticular tissue between the fibres of this tendon was the part chiefly engaged in these injuries. In the discussion that ensued in the Society, one of the speakers seemed to think that in all such accidents the tendon was diseased, broken down into this kind of mesh-work, not snapped across. We can scarcely conceive a force, indeed, to tear across a tendon. As to the mechanism of the accident, so to speak, the Society did not seem clear. Dr. Jacob appeared to think, that in complete dislocation, the tendon was not put on the stretch at all, but rather the reverse, while Mr. Adams alluded to a variety of the accident—partial dislocation, of course—which he had seen in museums, where rupture had certainly taken place. Both were, perhaps, right. A tearing of the tendon of the subscapularis is, however, more frequent than either. The capsular ligament, of course, shares the same fate, and the case is of some five or six weeks' anxiety to the practitioner. The accident is of interest from the fact of John Hunter and Munroe having suffered it, being quite as vulnerable in another tendon as the hero of antiquity from which it gets its name.

At the Royal Irish Academy a somewhat interesting announcement, as regards the fauna of Ireland has been recently made—namely, the existence at one time of the black bear of Northern Europe in these latitudes, taken in connexion with the Irish elk, so peculiar to this country, and so well known, the discovery is considered one of great moment. Mr. Ball, it is said, has had communication with Professor Owen as to the identity of the bones with those of the animal named, and the able and learned successor of Hunter in England has given an opinion quite in accordance with that of the Academy. The crania were found between seven and eight feet under the surface. The black bear is now met very rarely, even on the Alps; in America, however, it is more common. It is not to be confounded, of course, with the white bear of the Polar circle. The black bear, unlike the brown, is not carnivorous, so that more than ordinary care is necessary to decide the question. At the Academy it seemed settled.

And, talking of crania, perhaps it may be mentioned that a very learned discussion has been going on in Dublin of late on this question—"Who are the Celts?" Dr. Wilde contending he can decide by some crania in his possession, his opponents placing greater confidence in historic records, and the analogy of tongues. At the English side of the water the question is pretty well understood, the old piece of superfluity—putting a candle in the sun—to open it up at all. Perhaps the Colleges would decide it; for they seem in a something of a perplexity to know who their Celtic pupils are to be, the allowance already being a pupil and a quarter to each Professor; some malicious people saying only eight pupils to sixteen lecturers. In Galway very peculiar inducements, too, have been held out to the gentlemen of the Claddagh by Dr. Croker King, who opened the College there, that, whereas in the metropolitan schools, a degree of M.D. costs somewhere about 150*l*., he would let them have it at "tremendous sacrifice," &c., for the sum of 47*l*. 13*s*.! Sir Robert Lane, in Cork, too, who purposes, he says, to walk in the steps of St. Finbar, he that gentleman more or less a follower of Liebig and the alembics of Giessen, proffers similar inducements—nay, more, sixteen scholarships in science, of the value of 30*l*. each, are held out as a bait, and a botanic garden has since been added to complete the arrangements.

The opening lectures have been excellent, more especially that of the indefatigable assistant at the Rotunda, Dr. Doherty, on "Midwifery." After making the Galway folk particularly happy on the erection of their College, and excusing, *selon les regles*, his unaccustomedness, &c., to public speaking, the Lecturer entered on the peculiar subject of his course. A case of questionable pregnancy was supposed, with the paramount necessity of the Practitioner knowing his business, as on it the character, nay, very existence, of his patient depended. A case of neglected hæmorrhage and death of a young mother were enlarged on, with the absolute necessity of men being fitted for this department of Medical practice; the Lecturer very happily illustrating the matter by the old comparison of the table with different-shaped holes, with a plug for each; but, somehow "the round man getting ever and anon into the three-cornered hole." The necessity of general Medical education, including Surgery, Chemistry, Botany, &c., was also placed before his auditory,—Midwifery, of course, in particular, the history of which was traced from Hippocrates and Galen down; the latter, it seems, recommended "version," and the origin of the speculum was traced to Paulus Egineta. The modern French school of Boivin and Duges, Dr. Doherty alluded to in high terms; the Copenhagen Lying-in Hospital, he stated, was the best, perhaps, in Europe; thirty-six women were taught as midwives there every year, and sent into the country at the expense of the Government. In Norway, too, 400 women had been educated, the Storthing finding the funds; and in the Dutchy of Baden, under Naegele, the same obtained.

The recommendation of Professor Doherty for Ireland was, a set of "*Lying in cottages*" in preference to an Hospital, to prevent puerperal contagion and fever.

The stethoscopic labours of young Naegele were alluded to; but our own Evory Kennedy has done, perhaps, as much; the discourse winding up with the honoured labours of Simpson, Montgomery, and Murphy.

The Lecture of Professor Brown on Surgery was also one of no inconsiderable merit. After some general remarks, and others, consisting of a history of Surgery from its more immediate origin in Egypt, the Lecturer alluded to Larrey's account of the surgical basso-relievos at Luxor, curiously enough turning up now again through the labours of Layard. The history of Surgery in Greece was dwelt on. Opium and venæsection, the Lecturer stated, were known as early as Homer; the dark ages—the fourteenth century, when Pitard made the first College—were next passed in review, with sundry other matters.

The Inaugural Lecture on Materia Medica proved also chiefly historical. The use of anesthetics was traced to the 16th century, when a peculiar preparation, (chanvre) possibly Indian hemp, was used by the Chinese for the same purpose we use chloroform. The endless subject of pure Physicians and pure Surgeons was dwelt on at considerable length,—the former manipulating at the dissecting table in kid gloves and lavender water, (it must assuredly be in Connemara,) were rather roughly handled. The "Lady Bountifuls" of the west next came in for a touch of the lecturer's quality, and a flood of hard words let loose on them. The real subject in hand was next glanced at—the poisonings and *ignorance* (?) of English Practitioners. He should have spoken of Jupiter's satellites, rounding some fine periods, and bringing up the peroration. The Colleges are now fairly afloat; the results to Medical literature and Medicine in Ireland, is one of no inconsiderable anxiety. Whether the School in Dublin, which has so long maintained its character, can bear such Government competition, remains to be proved.

The Surgical Society has had another of its highly interesting meetings, and a point mooted by Dr. Kennedy, has created no small degree of discussion,—Whether, in fatty degeneration of the heart, in other words, in weak-acting hearts, we are right in recommending strict quietness and rest, as is usually done, in preference to exercise, the normal condition of this muscle. From a statistical summary of over fifty cases, the speaker was inclined to believe, that in all such cases the valves were healthy; that stillness but increases the disposition to disorganisation; and from the analogy of other muscular structures, we were not perhaps warranted in the ordinary practice. The discussion that ensued was much to the point; the old practical men, it must be confessed, leaned rather heavily on the author; but, for the present, the matter seems anything but decided.

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, WM. S. ORR AND CO.

THE MEDICAL TIMES.

SATURDAY, DECEMBER 22, 1849.

ON the 10th of June, 1847, a member of the Medical Profession, Dr. Richard King, thus addressed the Right Hon. Earl Grey:—"My Lord,—One hundred and twenty-six men (a) are at this moment in imminent danger of perishing from famine—Sir John Franklin's expedition to the North Pole in 1845, as far as we know, has never been heard of from the moment it sailed." Who was Dr. Richard King? from whence proceeded the voice of warning which thus foreshadowed the two years and a half of most painful suspense which have passed since that time? Dr. Richard King, in 1833, volunteered his services to accompany Commander Back, in a land expedition in search of the two Rosses—the uncle and nephew—who had made a voyage in search of a North-west passage, and for the safety of whom apprehensions were entertained. Of the energy of character, boldness and prudence displayed by Dr. King, there has never been, so far as we know, but one, and that a most favourable, opinion; further, there are many like ourselves, who believe that quite as much of the guidance, safety, and general welfare of that expedition was due to its Surgeon as to its Commander. Dr. King is thus spoken of by Sir John Barrow, when alluding to the researches in natural history as some of the fruits of the expedition:—"It is impossible not to bestow the highest degree of praise on Mr. King, who, with great exertion and diligence in collecting, and careful attention in preserving them (the collected objects), must have undergone much labour and constant anxiety." Upon the same gentleman does Sir John Richardson pass the following encomium:—"These specimens were all carefully prepared by Mr. Richard King, surgeon to the expedition, who deserves the thanks of zoologists for devoting so much time and labour to the promotion of science." Sir John Ross thus honourably alludes to one of those who went in search of him:—"I must, in the first place, do justice to the humane and praiseworthy intentions of Dr. King, and, in the grateful remembrance of his noble conduct in volunteering, with the gallant Back, to effect my rescue, the proposition which he has now made is only what I might have expected. Were the expedition which he proposes necessary, there is certainly no person in every re-

(a) According to Sir John Barrow 138 men—Erebus 70; Terror 68.

spect so eminently qualified to conduct that service as this enterprising individual."

A Contemporary (the *Athenæum*) thus writes also, "Dr. King has for years been urging through our columns and elsewhere geographical views, which the progress of discovery has now confirmed, as well as practical opinions on the best means by which Arctic discovery was to be pursued, that have been singularly justified by the series of events. It is incumbent on us now to direct attention to the confirmation which his views have already received, and the right which that circumstance unquestionably gives him to a hearing, whenever the measures best adapted for the recovery of Sir John Franklin and his band of adventurers have to be discussed."

Dr. King, then, *appears* to have been a person qualified to have commanded the attention of the Admiralty, and to ask the right to be listened to by Arctic geographers. It might have been that he would have done so, and have been attended to, had not his name at the same time been associated with—to some persons—most disagreeable and troublesome recollections. According to the *Athenæum*, "we believe it is a fact, that, on the return of the expedition in search of Sir J. Ross, Dr. King differed materially from Captain Back in regard to the survey which that gallant officer had made. He maintained that Cape Hay was not, as Captain Back had drawn it, the northern extreme of the western boundary of the great Fish River Estuary—that the Polar Sea to the north of Lake Garry formed a great bay, and that North Somerset was a peninsula. All these opinions have now been established as truths. The verification of these important features entitles Dr. King, as we have said, to a high position as a scientific geographer." [No. 1046.] Besides these things, which have placed Dr. King in the peculiar position in which he stands with the Admiralty, &c., *unfortunately* his last effort with regard to the expedition in the Terror, under Sir G. Back, closed with these words—"That those who were sanguine as to the success of that enterprise would be grievously mistaken; and should that insane portion of the instructions—the crossing the isthmus dividing the waters of Wager Bay from Regent Inlet—be attempted, the most disastrous results might be expected." How far Dr. King was correct, the Government had sad proof.

Unfortunate Dr. King! Thy rewards have followed too surely thy foresight. As you yourself say, your "services in search of Sir John Ross not having been even acknowledged by the Colonial or Admiralty Board," and that you "have pleaded nine years in vain." Is it not true, too, that your Communication on the subject of a North-west Passage, addressed to the Geographical Society in 1836, was neither acknowledged to yourself nor to its communicator, nor was it read before that Society, nor published in its Journal, though communications on the same subject, and at the same time, were both read and published from Ross, Franklin, Barrow, Richardson, and Beaufort? (*Vide Athen.*, 1016). Are we not also right in affirming, that when "the Admiralty consulted almost every officer in their service and within their reach, who was employed in the Northern Expeditions," and which, we are told, it did "on the highest official authority," you, Dr. King, were neglected and passed over? Are we far wrong in asserting, that there was something peculiar in the manner in which the Board of Admiralty met your offer to administer medical relief to the suffering crew of the steamer Eclair, and in the suppression of your name in the return made to the House of Commons, on the motion of Admiral Dundas, and ordered to be printed, of officers and men who volunteered to serve on that occasion? But, we forget—our readers by this time will have had enough information as to the nature of the source from whence sprung the warning given to the Admiralty two years and a half ago,—a source not unyielding of its recommendations, pregnant with truthful prophecy, even more than two years before that period; for we were told by Dr. King in 1847, that "it is greatly to be regretted that Lord Stanley did not entertain the plan which I proposed for acting by land in concert with Sir John Franklin's expedition by sea. It is scarcely possible that the two services could have missed each other; therefore, there would not have been that anxiety for the fate of Sir John Franklin which *now* exists, nor the necessity, which is *now* paramount, for the most active and energetic exertions for his rescue." The plan alluded to was suggested by Dr. King in February, 1845. No sooner had Dr. King, in June 1847, asserted the probable danger of the Erebus and Terror, and recommended immediate efforts for their succour, than we were informed, in a dogmatic *bulletin* dated from Somerset-house, and said to be constituted of "facts which may be relied on as having the highest official authority;" that the not having heard from Sir John was to be looked upon more as an earnest of success than of failure; that there was no cause for flying to his rescue; in fact, that there did not exist then more reason for apprehension than there was when the expedition sailed; finally, that it was clear that there were no grounds whatever for the assertion, that 126 men were at that moment in danger of perishing from starvation, seeing that Sir John Franklin was provisioned for the summer of 1848. The public became apprised, at the same time, that it would not be before the spring of 1848 that a company, headed by Sir John Richardson, would proceed from the Mackenzie River, in the event of a doubt still hanging over the fate of the Arctic voyagers.

Assuming that Sir John Franklin was provisioned for the summer of 1818, no doubt can exist but that Dr. King's assertion, that the expedition was in danger of *starving* in June 1847, was wrong. But this has little to do after all, with the truth of the spirit contained in all of Dr. King's warnings—viz., that of imminent danger and probable failure in all respects of Franklin's expedition — warnings which were asserted to have not had a shadow of truth in them, even though they were couched in such terms as the following:—"If Sir John Franklin has attempted to make a short cut westward, instead of sailing southward along the western land of North Somerset, and wrecked himself on Banks and Wollostan Land, he has run headlong into that danger of which I expressly warned him." (1847)

Two years and a half have now passed since Dr. King's warning, and no one knows whether the crews of the Erebus and Terror have been starved, or wrecked, or what has become of them. To the truth of their danger, whatever that may be or have been, Dr. King was then a witness, as he was to the fact of the geographical mistakes and useless purposes of preceding Arctic sea expeditions. It was stated (*Athenæum*, Nov. 24, 1849), that the Council of the Royal Society had memorialised the Admiralty as to the expediency of summoning all the Arctic naval officers to its councils, with the view of learning from them the best course to be pursued in resuming the interrupted search for Sir John Franklin. May *we* urge, not *now* the *justice*, but the *expediency*, of its not having forgotten Dr. King amongst the number of those consulted. We shall probably again recur to this subject.

DR. R. JAMIESON'S INTRODUCTORY LECTURE AT ABERDEEN.

A FRIEND kindly forwarded to us a copy of an Aberdeen newspaper, and in it we read a Lecture by Dr. R. Jamieson, introductory to the Medical Courses delivered in King's College, Aberdeen. The Lecture contains no small share of good sense, well expressed, and, in general, excellently adapted for the information of the student at the outset of his studies. The Lecturer's mode of handling his subject brings forth a great deal of illustrative imagery, so to speak, and his style is highly figurative. As these qualities are well sustained, we shall not venture to call them defects; nay, we are rather disposed to admit,—though they rather exceed in amount what good taste dictates, and certainly would not have commanded the approbation of Dr. Gerard, the Aberdeen authority on Taste in the last century,—that they contribute to render the Lecture, which is on a somewhat dry subject, more attractive to the young student. We can imagine, however, that Dr. Gerard's work is not read in King's College, to which Dr. Jamieson belongs, as we find, on examining our Biographical Dictionary, that the author of the Essay on Taste was a Professor of Marischal College. And this touches the point in Dr. Jamieson's Lecture which we think most open to criticism, namely, a fierce attack on the rival Institution of Marischal College, mixed up with like invectives against the senate of the University of Edinburgh, on account of some real or supposed injustice, committed jointly by the two bodies against Dr. Jamieson's "Alma Mater," King's College. It may be, that we do not understand the precise ground of offence; but we are quite sure that Dr. Jamieson has violated all propriety, by introducing into a discourse, expressly designed to exhibit to Tyro's in the Profession the true character of medical education, and a just model of what the Student's after life should be; in short, into a Discourse which should have breathed throughout the very spirit of Medical Ethics—a series of invectives, prompted by that personal jealousy which, though now fortunately lessening every day, has so long proved the bane of the Medical Profession.

Most of the readers of the *Medical Times* probably require to be reminded that, besides Aberdeen, the chief town of the county of that name, there is, at a short distance, the remnant of an ancient city, commonly called Old Aberdeen, which, though hardly more than a village in size, is the seat of King's College and University, founded at the end of the fifteenth century; and that in the modern city of Aberdeen, sometimes called New Aberdeen, though that name appears to date nearly from the period when the University was founded in the old city, there is another seminary, Marischal College and University, founded about a century later. Marischal College possesses four Medical chairs; namely, those of Medicine, of Chemistry, of Anatomy, and of Surgery. King's College, in the old city, has only one Medical chair, namely that of Chemistry and Medicine conjoined. But both Universities eke out their curriculum of Medical education by lectureships established by the senate of each. Dr. Jamieson is Lecturer on Medical Jurisprudence in King's College; and, as far as we can judge, the source of his indignation in the passages of the lecture referred to is, that the University of Edinburgh admits attendance on the four Professors of Marischal College, two in each of two years, as a part of its curriculum for the degree of Doctor; while it acknowledges no part of the Medical education at King's College, because the attendance on the one Professor there does not constitute an "Annus medicus." "Hinc illæ lacrymæ!" The University of Edinburgh, we presume, acts on a general rule. It must refuse the courses given by the lecturers in Marischal College as well as in King's College, as it refuses the lectures given by those who are not University Professors all over the world. Yet Dr. Jamieson, addressing inexperienced students, describes the conduct of the Senate of the University of Edinburgh as "selfish, impertinent, illiberal, and unjust," and all the while so colours his statement, as if this kind of conduct were directed in particular against King's College, and in a special manner to support the rival Marischal College, which, in his indignation, he calls a falling school, refusing to it the name of a University, terming it a "Gymnasium;" in short, teaching "the young idea how to shoot" in the most approved vocabulary of spiteful declamation. Our feeling, in regard to this part of Dr. Jamieson's lecture, is more akin to pity than to anger, to see a man of talents and judgment, on an occasion when he should have been particularly on his guard against any sentiment having the remotest appearance of personal pique, giving way to passions which blind his reason, and lead him to conclusions so perverse and alien to the plain facts of the case, that the youngest student who heard him intelligently must have laughed in his sleeve to see the headlong fury of the late moralist, his teacher, as soon as he encountered a topic which touched his self-love and class-interest.

THE BOARD OF HEALTH AND THE POOR-LAW MEDICAL OFFICERS.

Since the formation of the new Metropolitan Commission of Sewers, and the subsidence of the Cholera, it is difficult to conceive what duties can devolve upon the General Board of Health. We believe that the Board itself is rather puzzled to know how to occupy its time and to furnish a decent excuse for its further continuance. Mr. Chadwick fidgets for a new grievance, and looks dismally unhappy in his morocco chair, because he is not surrounded with piles of reports, experimental suggestions, and statistical tables. Dr. Southwood Smith wanders listlessly through the forsaken halls of Gwydyr House, meditates a new crusade against filth, and practises elocution with the attentive walls for an audience, and for plaudits the echoes of his own periods. As for the titled members of the Board, the Earl of Carlisle cons over the dictionary of rhyming terminations, and writes sonnets in imitation of Petrarch; or elaborates a sentimental address to dignify the inauguration of a wash-house or a model prison. We are sorry to see great talents "waste their sweetness on the desert air;" and we think that we may save these official dignitaries the horrors of a painful dissolution, by suggesting to them the expediency of taking under their especial direction the Union Medical Practice of this country.

The time is now past for exhibiting the evils arising out of the administration of medical relief and general relief by one and the same authority; for it is admitted on all hands, that satisfaction can never be given to the poor, the rate-payers, or to the medical officers, until the administration of medical relief be separated from that of general relief, and the medical officers are rendered independent of Boards of Guardians, and are made responsible to an intelligent, medically-instructed, governing Board. The jealousies and heart-burnings among medical men arising out of competition for office under the present system; the supercilious department of Local Boards, and their unfeeling promptitude to take advantage of professional rivalries, in order to lower the standard of payment, without reference to the competency of individual claimants, or the preferences of the poor recipients of their ungracious charity—the complaints, both deep and loud, of the labouring class themselves, to the effect, that they are tortured by a cruel system, which the humanities of medical science are not permitted to meliorate; and the frequent legal suits between medical men and the Boards of Guardians respecting disputed payments, on which occasions the Boards rarely scruple to plead their own neglect of duty, as in Mr. Tatham's case, to wrong their medical officer;—the undignified quarrels between the Central and the Local Boards in their contest for supremacy and independence, and the unscrupulous compromises, by which they consent to sacrifice their Medical officer as an offering to conciliate a temporary pacification,—all these are notorious evils inherent in the system, and are both irremovable and immitigable whilst the anomalies of the present complicated scheme of administration are in force, and they cry aloud to the Government and the Legislature for an instant and entire change.

The instrument of such a change exists in the General Board of Health, always premising that this Board be composed of a majority of Medical men; for otherwise it is impossible that any satisfaction can be given to the Profession. It is not to be presumed, that in the event of an alteration of system, the Government would introduce a new Board of Admiralty into the Medical Profession. The Union Surgeons have, for a long time, memorialised to be placed under the Government of a Medical Board, because their peculiar duties cannot be understood or appreciated by a mere layman, and cases of alleged malpractice can be decided only by a duly qualified Medical referee. There can be now no practical difficulty to the gratification of their repeatedly expressed wishes, for the present Board of Health, once reconstituted, being subject in all its operations to the laws of hygiene and medical science, would really form the natural head of the service. The subordinate objections arising out of the mode and source of payment of the Medical Officers, could be easily got rid of by a Government effectually disposed to make an organic change in this department; and these objections are now suggested, in our opinion, merely as excuses for delay, and to drive off the moment of action and of responsibility. We do not think that it is a matter of much consequence, whether the Medical Officer of a Union be paid by means of a per-centage on the rates, or from the Consolidated Fund, provided that there be a clearly defined scale of remuneration established. There can be no doubt that the latter is the most essential point for which the Union Surgeons should contend, since no system can work beneficially for them, of which this does not constitute the corner-stone. The mere shifting of allegiance from the Board of Guardians to the Poor-law Commission, and from the Poor-law Commission to the Board of Health, and from the Board of Health, perhaps, to some other Governmental machinery, would be but an idle trifling with the wishes and interests of the Medical Officers; but if, simultaneously with such a change of jurisdiction, powers were given by Act of Parliament to enforce a higher standard of payment for medical relief, this branch of the Profession would receive substantial and permanent benefit.

When we consider that during the season of panic and peril, when thousands were struggling for life under cholera, and tens of thousands were trembling with dread of an attack, the Board of Health usurped an uncontrolled jurisdiction over the Poor-law staff; and, as we may be assured, that, in all cases of similar emergency, it will exert the same paramount authority, we cannot but admit the propriety of investing in this Board the sole jurisdiction over the Medical Staff in respect to ordinary as well as extraordinary duties; and we are persuaded that such an alteration effected on the conditions we have expounded, would be a signal benefit to the Medical Officers, a blessing to the poor, and an enhancement of the dignity and independence of the entire Profession.

THE METROPOLITAN SEWERS COMMISSION.

The proceedings of the Commissioners who have undertaken the Herculean task of ridding

the Metropolis of its noxious sewage matter have lately been diversified by a little episode, involving a question of some importance. It appears that one Mr. Hale, a Civil Engineer, was appointed by the members of the Commission to assist the "Trial Works Committee," in conducting a series of experiments on the discharge of water through pipes, and that an account of some of these experiments appeared in the *Mechanics' Magazine*, in an Article to which the signature of Mr. Hale was appended. At a General Court of Commissioners, held in the course of last week, Lord Ebrington, the Chairman, charged Mr. Hale with having, by the publication of this article, committed "a somewhat singular breach of discipline," evincing "an ignorance of the propriety of behaviour," and not only causing embarrassment to the Court, but "tending to embarrass the public." Now, we are not concerned to give an opinion, whether Mr. Hale was or was not guilty of a "breach of confidence" and "gross irregularity." He has been judged, condemned, and punished by the Court of Commissioners, and it is not our business to dispute the justice of the sentence of suspension pronounced upon him. Neither do we care to inquire how the publication of the result of the experiments could be embarrassing to the Commissioners. We only wish to ascertain whether there is any real ground for Lord Ebrington's fear that it should embarrass the public.

The reason assigned by His Lordship for such a supposition is, that the article in question "purported to impart as authoritative information that which had not been decided on by scientific men." Now, if we rightly apprehend the meaning of their words, we think the reason insufficient. If a series of experiments in connexion with a subject of public importance be conducted at the public expense by a person of competent ability, we do not see why the public should not see a plain narrative of the experiments and their results, even before they have been "decided on" by other "scientific men." It is notorious that scientific men differ very widely on questions which have not been settled by actual experiment, and we consider information derived from practice to be preferable to an opinionn grounded on theory. A deceased lawyer, of great eminence, who had asked the opinion of one of his pupils on a question of law arising out of a given statement of facts, is said to have interrupted the pupil's, "Why, Sir, upon principle"—with the words, "D— your principle: have you got a case?" We confess we do not clearly see how the theories of even scientific men can countervail a case made out by actual experiment; but, if their opinion be requisite, how can it be better obtained than by laying the result of the experiments before the world in the columns of the public journals?

We think that Lord Ebrington is inclined to make the proceedings of the Court over which he presides too mysterious. The day has gone by for keeping the public in the dark as to matters of such importance as the sewage question. If our memory does not deceive us, the facetious H. B. once depicted a Lord Ebrington as Mrs. Partington trying to keep out the Atlantic with a mop. We do not wish to see the caricature repeated. The general history of Commissions has been, that after the appointment of the Commissioners the public has known nothing about their proceedings. It is true that, in the course of years, a tremendous Blue-book makes its appearance; but few or none attempt to read it, and the chief recommendation of its thickness is, that waste paper is sold by weight. The proceedings of all present and future Commissions will, like the sewers, be all the better for a thorough ventilation; and we recommend the concluding sentence of Sir J. Burgoyne's observations to the notice of his colleagues, as admitting the advantage of "establishing a free vent to the open air."

THE DEPUTATION TO THE ROYAL COLLEGE OF SURGEONS.

THE Deputation from the Conference held at the Hanover-square Rooms, had an interview, on Wednesday last, with the President and Vice-Presidents of the Royal College of Surgeons, for the purpose of ascertaining the extent of the alterations proposed to be made in the Charter of the College, and to lay before the Council certain propositions containing the main principles upon which those members of the College who desire to open the College of Surgeons to the whole body of Surgeons, wish to see the College re-constituted. The Deputation were received with great courtesy by the President and Vice-Presidents of the College, who listened with much attention to the representations made by the members of the Conference.

Mr. Clifton, the Vice-President of the National Institute, introduced the Deputation, and explained, that the Council of the National Institute had convened the Conference, in order to secure unity of sentiment and action, and to pave the way for a definitive and satisfactory settlement of the medical question. He stated, that there were many Members of the College who were opposed to the establishment of a new College of General Practitioners, on the ground, that the College of Surgeons ought to be converted into such an Institution, and might be made such if suitable efforts were directed to that end. To ascertain the disposition of the Council of the College in this respect, and to give the gentlemen who held those opinions an opportunity of expressing them to the Officers of the College, the National Institute had convened the Conference, and sought for the present interview; and he hoped that there would be, on all sides, a candid interchange of opinions upon this important matter.

A series of propositions was then read by Mr. Bottomly. These propositions were stated by that gentleman to imbody the views of those Members of the College who were also Members of the Society of Associated Surgeons. They contemplated, generally, the establishment of two grades in the College; the one that of Members under ten years' standing, and the other that of Fellows above that status, together with an order of Fellows by examination. It was proposed, that the Members should elect, by means of voting papers, the Fellows of the College, and the Fellows the Council, whilst the Council should have the privilege of nominating the Examiners.

Other propositions provided for the Institution of examinations in Medicine, Midwifery, and Pharmacy, and advised that Members of the College practising medicine and midwifery should be entitled to a seat on the Council; but, that the majority of the Council should be what is denominated, "pure surgeons."

The President, having received the propositions, stated, that he was unable to express an opinion upon them, as the Council had not yet seen them, but that he would submit them to the Council, and return a reply in conformity with their decision.

The resolution of the Council of the College, by which they had agreed to apply to the Crown for an alteration of the Charter, upon certain principles specified in the resolution, and which are the same as those referred to in our leading article of last week, was read to the Deputation. After a short discussion upon the various topics brought under review, the Deputation withdrew.

PUBLIC HYGIENE.

DRAINAGE: AS IT AFFECTS THE HEALTH, WEALTH, AND MORALITY OF SOCIETY.

No. II.

Cleanliness of Person and Abode enforced.—Ignorance and Indifference of Builders, Landlords, and Tenants.—Mechanical Exposition of the Main Features of the Old and Present System of Drainage.—Its Evils affecting all Classes of the Community.

A certain tyrant wishing to justify his cruelty to his slaves, declared that they were not to be regarded in a different light from the lower animals, —in proof of which he tried the wicked and invidious experiment of ordering a slave to lie chained to a dog kennel, and made to lead the life of a dog for a month. "Now," said he, "there is the man, and there is the dog, and the lengths of their chains are equal. Which is the most revolting to the senses?"

The dog was in his natural state; but the man was a hideous object, dying of filth and fever.

From this act of a wretch, who thus outraged the self-evident ordinances, both of God and man, it is possible, nevertheless, to extract a most important lesson. Cleanliness of person and of abode, by every care and consideration that belong to a decent and sensible mind, are shown to be a pre-eminent duty in man, from the repulsive, if not fatal consequences, which attach to their disregard. "A cottage with a cess-pool at the back, or beneath the floor,—a mass of stagnant household slush before the door,—a ditch, or open drain, running close beneath the windows,—how many hundreds of such abodes are, at this very time, to be found in almost every city, town, and village throughout England! In how small a degree do these cottages and hovels differ from the dog-kennel just described,—a kennel to which such countless numbers of men are, at the present time, chained by poverty, cruelty, and ignorance, with all their consequences of filth and vice, disease and death,—carrying with them their natural vengeance upon society in pestilence and devastation.

Without considering the ultimate injury to health, one would have thought, abstractedly speaking, that the very fact of a constant appeal to the senses, in the shape of annoyance or disgust, would have induced attention to the question

house-drainage at a very early period of civilization. But all experience has, unfortunately, shown, that this has by no means been the case. Whether, by habit, the sense has become blunted, or that the annoyance has been supposed a thing beyond remedy, and one of the necessary evils of life which everybody must endure, nothing is more certain than that a marvellous insensibility, or at least an indifference, has characterised all classes in this respect, not excepting the majority of the highest, as we sufficiently displayed in our Paper of Dec. 1. If tenants have been thus indifferent, it is no wonder that landlords and builders have been slow to learn.

Since tenants, knowing no better, have been in the habit, from time immemorial, of putting up with almost any house-nuisance that might be inflicted upon them, as though they were "born to it," a system of drainage of the worst kind, for the best class of houses, has been regularly adopted; while, by no very finely graduated scale of descent to houses of low rent, this worst system arrived at an evasion of drainage of any kind whatever; an open gutter conducting everything to a cesspool.

The old, which is, in almost all cases, the *present* system, may be thus briefly described:—

Materials and Structure.—The materials for the construction of house-drains are brick, usually of the commonest kind, (being out of sight); they are generally permeable, and laid together at the bottom without cement or mortar. Hence they are soon soaked through, and become filth-filters, penetrating and saturating the soil beneath them, thus generating their own decay, while they continually cause foul exhalations which "nobody can account for,"—find their way into cellars, to the abomination of the "coals" and the horror of the "wine," or make their insidious way into the well of the pump, to the profit of the plumber, whose efforts to cure the stench of the water are invariably baffled by his total ignorance of the cause.

Form.—The house-drains are always built in circles, octagons, or squares. Of the first, which are far better than the others, (though by no means the best forms for house drains,) we will merely say, at present, that they are far less numerous than the others. The objections to the octagon and the square are, on account of the angles they present for accumulations of all kinds, independent of the obvious fact, that their form is very unfavourable to the free and regular flow of the sewage. Hence they have a constant tendency to be partially choked up, and often they are entirely so; either circumstance causing very great annoyance and inconvenience, besides the expense attending the digging down to, and breaking into the drain for cleansing and repair, after vain attempts to effect the former by flushing.

Dimensions.—Our dimensions of house-drains are all on a false principle. They are generally too large by half, or two-thirds, often by three fourths; not unfrequently, they are five times beyond the proper dimensions. The consequence of this is, the regular accumulation of all manner of sediment, deposits, and obstructions, which the largest amount of water that occasionally flows through the drain is quite unequal to displace and carry onwards, because of the large surface over which its flow is distributed.

Construction.—House-drains are commonly built without a due calculation for their decline and fall; very often, indeed, they run upon a dead level, (so that the flow has to wait for rain or other flush of water;) and, sometimes, they absolutely incline the wrong way, and the sewage, met and driven back by the surface water, accumulates in a huge cess pool, which continues to swell in its pestilent bed till some day there comes a great ingress of storm-water, and the monster-nuisance rises of itself, and seeks its own relief, to the temporary disgust and ultimate joy of the innocent tenant, who had never thought of helping it to effect its escape.

In the construction of branch-drains there is also the common evil of joining them with main, or larger drains, at right angles,—a gross engineering blunder, as this must encourage all sorts of deposits, accumulations, and impediments.

Traps.—The traps usually employed in houses are the bell-traps. These are, *of course*, (we were about to say,) the worst sort of traps. They are always too small, so that the water they hold soon becomes impregnated with the bad odour it is meant to govern, making the remedy the same thing as the disease. Besides this, they are too easily displaced.

Cesspools.—But not only are the drains built of the worst materials, and constructed in the worst way, but very often the houses themselves are built so as to favour this evil to the utmost, if not even to prevent all chance of improvement. In localities that lie low, the houses often have the kitchen or basement floor at a lower level than the main sewer, as though the intelligent builder had intended the main sewer to have its outfall in these new houses, and make a series of cesspools of all the kitchens. Other houses (we do not speak of the poorest class) have no main sewers near them into which their drains can be carried; so that, if the tenant had a "bright thought" of getting rid of his pestilent accumulations, and if even his landlord were a man who could see some sense, at least in keeping down and moderating the aspirations of a cesspool, there is still no hope for him,—the enjoyment of drainage into the common sewer, and the blessing of a sweet house, are for ever denied him.

Of the prevalence of cesspools, we may simply say, in the most general terms, that not only has the practice of having a cesspool been common to every house of every description, from the lowest up to the highest, but the consideration and perception of the importance to health of getting rid of them, has only been enforced upon the public mind within this last year or two, at the utmost; and even now the builders, landlords, and the tenants themselves, are slow to awake and believe in the advantages of a total abolition of these sinks for the generation of fever.

If pump-wells, and wells of all kinds in contiguity with the common sort of brick-drains and sewers, are frequently tainted by the saturation of the intervening earth with the sewage, how much worse must this be in cases where a cesspool, or a series of them, lie within a few yards of the brick-work of the wells?

Independent of the constant nuisance and danger to health and life in the presence of these cesspools, the expense they entail (without reckoning the apothecary's and undertaker's bills) is very great, in all houses where it is considered wise to have them occasionally emptied.

And this question of emptying and cleansing out of filthy sinks and cesspools brings us to the dwellings of the working classes and the poor, who live in over-crowded courts, and lanes, and alleys, and cellars,—whose degradation, sufferings, and death, are out of sight and unknown. With them there is no such thing as drainage,—that is, no under ground or covered drainage. Every refuse of animal life, and of every other kind, is thrown into the cesspool or into the gutter which runs beneath their windows, the effluvia of which is the only air they breathe. The running gutter and the stagnant pools may be seen, and these are now and then cleared away by necessity, by parish authority, or by the blessed advent of a storm of rain. But the cesspool is never emptied, or rarely, if they can avoid it. They dread the expense. When full, it is covered over with boards, earth, rubbish, in the best way they can, and another is dug as near it as possible. As many as seven cesspools have been found in this way, lying festering in darkness, and in horrible proximity. While such abominations are fermenting within half a yard beneath their feet, and beneath their beds, it is no wonder that cholera and typhus break out in those localities where so many thousands of our fellow-creatures lead their miserable lives, unable to help themselves, and eventually becoming indifferent, vicious, and despairing.

Let us look to it in time. The dreadful warnings of the last visitation of cholera, which spared no favoured class, are fresh in the memories of all, so that we may profit by them if we will. That we should do so, is obvious for every reason. Besides our duty, as members of a Christian community, let us not be blind to the fact, that the misery and vice we permit to be generated by the filth of the poorest and most helpless, avenge themselves upon us in their *consequences*, which expand and ramify themselves throughout all classes of society.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

DECEMBER 11, 1849.

Dr. BURROWS in the chair.

ON THE IDENTITY OR NON-IDENTITY OF THE SPECIFIC CAUSES OF TYPHOID FEVER, TYPHUS FEVER, AND RELAPSING FEVER.

By W. JENNER, M.D., London,
Professor of Pathological Anatomy in University College, London, and Assistant Physician to University College Hospital.

(Communicated by Dr. SHARPEY.)

The author, at the commencement of his paper, remarks, that for many years small pox, measles, and scarlet fever were confounded under one name, and that it was only after the publication of Dr. Withering's essay, that measles and scarlet fever were regarded as distinct affections, *i. e.*, distinct as to their course, their symptoms, their lesions, and their causes. Typhus fever, typhoid fever, and relapsing fever, are yet, by many, looked on but as varieties of one disease; but the writings of Dr. Gerhard, M. Valleix, and Dr. A. P. Stewart, have rendered it highly probable that typhoid fever and typhus fever are absolutely distinct from each other—two species of disease, and not varieties of one affection. In the *Monthly Journal of Medicine* of the present year, the author has analysed the course, symptoms, and lesions of structure found after death in a certain number of cases of fever, and this analysis, he thinks, proves that, as regards their course, symptoms, and lesions, no two diseases can be more distinct than typhus and typhoid fever. But small-pox, measles, and scarlet fever differ also in respect to their exciting cause, which, in the case of each of these diseases, is specific. In like manner typhoid fever, typhus fever, and relapsing fever must require for their production the application of distinct specific causes if they be distinct diseases. To inquire whether the specific cause of each of these diseases is distinct, or whether the cause of all these is the same, is the author's object in the present paper. He first describes the peculiarities of the course and symptoms of relapsing fever, and of the skin eruption of typhoid fever, and of that of typhus fever, on which the diagnosis of these diseases rests. He then gives three tables, showing all the instances in which two or more cases of fever were admitted from one house into the London Fever Hospital in the years 1847, 1848, and 1849; the age, sex, and degree of intimacy of the individuals, as well as the nature of the disease under which they laboured;

and for the years 1848 and 1849, the number of all cases of fever admitted into the Fever Hospital during the separate months, with the rash of typhoid fever and that of typhus fever respectively. The results exhibited in these tables are—1st. That in 1847 there were five instances of the admission of two or more cases of typhus fever from the same house, two instances of the admission of two cases of typhoid fever from the same house, and five instances of the admission of two cases of relapsing fever from the same house, and not a single instance of cases of the three diseases, or even of two of them, coming from the same locality. 2nd. That in 1848 two or more cases of typhus fever were admitted from each of thirty-three houses; and two cases of typhoid fever from each of four houses; while there was only one instance of a case of typhus and one of typhoid fever being admitted from one house; and in this exceptional instance there is reason to believe the patients received their diseases from different sources. 3rd. That in 1849, two or more cases of typhus fever were admitted from each of eighteen separate localities; and two or more cases of typhoid fever from each of four localities; while in not a single instance was a case of typhoid fever and a case of typhus fever admitted from the same house. 4th. That in 1847, the relapsing fever, typhoid fever, and typhus fever, and in 1848 and 1849, the typhus and typhoid fevers, prevailed simultaneously in the metropolis; nevertheless, that the cases of these several diseases came to the hospital from distinct localities. In 1848, there were received into the fever hospital 118 cases of fever with the rash of typhoid fever, and 390 with the rash of typhus fever; in 1849, 118 with the rash of typhoid fever, and 143 with the rash of typhus fever. As, therefore, about one-fourth of all the cases of fever admitted in 1848, and nearly half of those admitted in 1849, were cases of typhoid fever, the author argues, that in the numerous instances in which two or more cases were admitted from one locality, cases of typhoid fever ought to have been mingled indifferently with cases of typhus fever, in about their proportion in the two years, if the cause of the two diseases were identical; while, as has been shown, from all the localities which yielded cases of typhus, there came but one case of typhoid fever. He remarks, moreover, that an increase of the epidemic prevalence of one of these kinds of fevers had no influence in increasing or diminishing the absolute number of cases of the other kind of fever; that no transition-cases were observed, marking the passage of one epidemic constitution into another; that the rash of typhoid fever and that of typhus fever were not modified in their characters by variations in the prevalence of other kinds of fever; and that the absence or presence of lesion of Peyer's patches and the mesenteric glands always corresponded with the symptoms of the particular cases during life, and did not depend on the epidemic constitution. The author then adduces some particular instances, in which a succession of cases, coming from the same locality, or apparently arising from the same cause, all presented the same characters. And in conclusion, he remarks, that the facts contained in this paper appear to him to prove incontestably, that the specific causes of typhus and typhoid fevers are absolutely different from each other; and to render it in the highest degree probable, that the specific cause of relapsing fever is different from that of either of the two former.

Very beautiful and accurate wax models of the eruptions in the two diseases were exhibited; the work of Mr. Treson, modeller to University College, from casts taken by Dr. Jenner, from patients labouring under typhus and typhoid fevers.

Dr. Barclay inquired of Dr. Jenner, whether he regarded all cases of fever, in which there was not any eruption, as instances of relapsing fever; and further, whether cases of continued fever, without an eruption, were or were not liable to relapse?

Dr. Jenner replied in the affirmative, relative to the occurrence of continued fever without eruption. About one-fourth of the cases under fifteen years of age were unattended with spots; and also 3 out of 21 from that age to the 22nd; after that age the eruption showed itself in all cases. There was not any eruption in one-fourth of Louis' cases.

Dr. Stewart could not but feel gratified, that the views he had ventured to lay before the medical world nine years ago on the subject which this evening occupied the attention of the Society, had been so fully borne out by the interesting researches of Dr. Jenner. He felt assured, when he published those views, that time and observation would thoroughly establish the fact;—for it was a *fact*, and not a theory,—that the eruptions of typhus and typhoid fevers were essentially and invariably distinct, and never passed the one into the other. One point to which he had directed attention in the paper alluded to, and which he thought had not yet been sufficiently investigated, was the frequent occurrence of true relapses in typhoid fever. By this, he meant that, not unfrequently, after the disease seemed to have run its course, and convalescence was almost established, a new attack was ushered in with fresh rigors, followed by febrile excitement, fresh rose-coloured exanthem on the skin, a repetition of all the previous symptoms, and, as might be proved by dissection in the event of death, which sometimes takes place after a second and even a third attack, with fresh intestinal lesion, and the development, amid the cicatrices of former ulcers, of new, highly swollen and elevated glands, both aggregated and solitary. Such a phenomenon as this was never met with in typhus. There might be sequelæ in typhus, but never true relapse. There was another point of great importance, of which he was lately reminded by his friend Dr. Gueneau de Mussy. The common answer of those who held the identity of the two diseases to those who showed them the intestines in typhus uniformly free from ulceration, and even from anything that could be called disease, was, that the malady had run too rapid a course for the characteristic appearances to be developed. The fact being, that the peculiar lesion of typhoid fever attained its maximum of development about the third or fourth day, from which time the process of disintegration seems to commence. The more rapid, therefore, the course of the disease, the more fully developed ought the glands to be. The inquiries instituted by Dr. Jenner, and detailed in his paper, regarding the localities from which the cases came, were certainly of deep interest; and he (Dr. Stewart) apprehended, that the most important question now demanding investigation, and the decision of which would go far to settle the controversy, was, whether an attack of the one disease generally protected those who had had it from the other, or whether, on the contrary, there were well authenticated cases of both fevers having attacked the same individuals. It was not strictly correct to affirm, that one attack of exanthematic typhus uniformly protected against another, for there was a considerable number of instances to the contrary. A very noted one, he believed, was Dr. Christison, who had had three or four attacks of true typhus, and was now obliged to refuse attendance on cases of that disease, as each succeeding attack was more severe than the preceding.

Dr. Barclay was not satisfied with the answer he had received respecting the occurrence of fever without spots. His own experience showed that that state of the skin was very common in fever, and the appearance of an eruption in fever was rare. Out of 111 cases that had occurred during one year, at St. George's Hospital, there were only 59 of all kinds of eruption. He himself found considerable difficulty in distinguishing between the different kinds of eruption attendant on, and said to characterise typhoid and typhus fevers, as, in some cases, he had noticed the rose-coloured eruption become of a dark hue, while in others no such change took place. He could diagnose between typhus and typhoid fevers, by the condition of the glands in the intestinal canal, and by the state of the tongue and of the abdomen, the excretions, &c., but not by the appearance of the patient's skin. The conclusion he drew respecting the eruptions was, that when the spots were dark-coloured, it was much less common to meet with intestinal ulceration. He had ascertained, by the examination of bodies after death, that when the rose-coloured eruption existed, there is always ulceration of the intestinal canal; in the dark-coloured eruptions that condition is always absent.

Mr. Sankey remarked, that when he first became connected with the London Fever Hospital, he held the same opinions as Dr. Barclay. His ideas were confused, and he did not know when he should and when he should not find abdominal lesions. He had found the same degree of confusion respecting these eruptions in the latest works on medicine. Watson, in speaking of the rashes, evidently confounded the two forms which appear in typhoid and typhus fevers. His description is that of the typhus eruption; but he mentions one symptom which belongs solely to the typhoid. This state of mental confusion was removed by the perusal of the last edition of Louis' work on "Fever," to which his attention had been directed by Dr. Jenner. He did not hesitate to say, that when the distinguishing characters of the two rashes are clearly understood, (and they may require some well-marked cases placed side by side to elucidate them,) there will never again be the least chance of their being confounded together; indeed, he added, the nurses of the hospital had learned to diagnose between the two forms of fever from the characters of the eruptions. So accurately can the diagnosis be made when either of these kinds of spots is present, that out of from 200 to 300 autopsies, there has not been a single error in the diagnosis, as to the existence or absence of disease in Peyer's glands. As stated in the paper, for two or three years past, the majority of cases at the Fever Hospital were instances of typhus; there were not, in fact, any cases of typhoid fever, and, consequently, ulceration of the intestines was not met with. While typhus was thus raging in London, the parish authorities of St. Margaret's, Westminster, their own infirmary being crowded, sent many cases to the hospital, chiefly of the newly-arrived Irish; these cases were all typhus. Before the epidemic was on the decline, fever broke out in the Westminster-school, and in the precincts of the Abbey. Two domestic servants of one of the prebendaries were admitted into the hospital, and their cases were clearly typhoid fever. It was supposed, at first, that the epidemic had spread to the precincts, but he (Mr. Sankey) stated to Dr. S. Smith, who had been directed to investigate its characters, that it must have arisen from some other cause than contagion, as it was essentially different from the cases previously under treatment from that neighbourhood, and, in all probability, was connected with some local cause. This proved to be the case, as a foul and obstructed drain was discovered passing at the rear of all the houses in which fever had broken out. He (Mr. Sankey) could corroborate Dr. Stewart's remarks as to the early occurrence of intestinal ulceration in typhoid fever, for he had seen, a few years ago, a case of extensive intestinal disease in a woman who was working on the Friday, and died of typhoid fever the succeeding Monday. The solitary and agminate glands were perfectly hypertrophied on that, the fourth day of the fever. He could readily conceive that confusion with respect to the eruption might arise, unless several cases, from twenty to twenty-five, were seen and examined at the same time. A number of cases were sent into the hospital as instances of fever, which in reality were not such, but cases of bronchitis, pneumonia, &c., with febrile disturbance. In fact, a disease has often been named fever, because it cannot be clearly made out to be anything else—by a process of reasoning by exclusion. If the disease be not (or, what is the same thing, be not discovered to be) inflammation of this or that organ, then it has ever been taught that such disease should be called fever; so that the word fever has been, as it were, a shelf on which to deposit those cases which do not readily fit any place in the nosological system.

Dr. Baly remarked that if the assumed fact Dr. Jenner had related, of the connexion of certain eruptions with certain forms of fever, be admitted as proved, then the additional fact, that cases of typhoid and typhus fever were rarely sent to the hospital from the same house, became very important, and would seem to show that they depend on different causes. They had had 117 cases of fever in the Milbank prison, while typhus and typhoid fever were prevalent without. Of these 117, about twenty cases ended fatally. In all these, there was great mischief in Peyer's patches and in the mesenteric glands. The cases in the prison were well-marked instances of typhoid fever. He

(Dr. Baly) was not very intimately acquainted with the characters of the eruption in typhoid fever, so as to be able to distinguish it from that of typhus, but from his general knowledge he was quite sure that a large number of cases may occur without any eruption at all.

Dr. West observed, that one form of fever which had not as yet been alluded to, the infantile remittent of children, had been considered by Barthez as identical with the typhoid of Louis, and in that opinion, he (Dr. West) agreed. It presented the same characters during life, and the same changes after death, as the typhoid described by Louis. The characteristic rash was, however, often absent. Among the poorer classes of society this form of fever is often very severe and even fatal. In no instance could he recollect seeing a case of infantile remittent when there was a case of typhus fever in the house, nor, on the other hand, could he recollect a case of typhus occurring when infantile remittent already existed in a house. These facts were, as far as they went, confirmatory of Dr. Jenner's views.

Dr. Webster inquired of Mr. Sankey if he meant to imply that medical men sent cases of pneumonia and bronchitis into the Fever Hospital, under the mistaken idea that they were cases of pure fever?

Mr. Sankey wished it to be understood, that in making these remarks, he meant other diseases than those the author of the paper and himself would call true fever. For, indeed, if every member of the Profession were agreed as to what cases were fever, and what were not; if the point were not an open question, there would be no discussion. The rules of the hospital expressly provide for the admission of all cases of febrile disturbance of a contagious nature, or likely to become such. In fact, cases of small-pox, acute rheumatism, pneumonia, bronchitis, &c., had been admitted even lately.

Dr. Heale was old enough to recollect the time when fever was said not to exist unless some acute lesion of an internal organ were present. He did not think it, therefore, very disparaging to mistake instances of bronchitis, pneumonia, &c., for cases of fever, especially when there was much febrile excitement. It was more likely to occur among the sick poor, the parochial surgeon being anxious to get rid of the charge of a case of complicated illness.

Dr. Webster inquired whether the author of the paper considered typhoid and typhus fevers at all contagious? It might be produced by other causes; and he instanced a case of eight people living in one room, all of whom were taken to the hospital with fever.

Dr. Barclay had tabularized the respective ages of patients in St. George's Hospital, labouring under fever, in whom the two different forms of eruption had appeared. From the age of 10 to 20, there were 5 rose-coloured and 3 dark-coloured; from 20 to 30, 7 rose, and 3 dark; 30 to 40, 5 rose and 3 dark; and from 40 to 50, 4 rose and 5 dark. The age of the patient influenced the duskiness of the eruption, the occurrence of which he considered to be casual, and depending on other causes than the peculiar character of the fever.

Dr. Merwyn Crawford thought that the difference of opinion between the physician to the Fever Hospital and that of St. George's, was owing to the fact that in the former hospital the patients were congregated together, and exposed to the influence of a virulent fever poison, and in the other the patients were disseminated throughout the wards, and the poison was much milder in consequence. He himself, like Dr. Barclay, was unable to recognise the exanthem. He believed the eruption was an accidental circumstance, dependent on an unhealthy locality and want of ventilation.

Dr. Jenner replied, that in common with all writers on typhoid fever, he had seen cases of that disease in which there was no eruption, and referred, in confirmation, to the analysis of cases he had published during the present year in the "Monthly Journal of Medical Sciences," (Edinburgh,) and that in the last week's *Medical Times* he had also shown, that the eruption was frequently absent in cases of typhus in children; that the paper he that evening had the honour of laying before the Society only spoke of the eruptions as diagnostic *when they were present*. Dr. Jenner then adverted to the fact, that the skin eruption was sometimes absent in scarlet fever and in measles, and to the bearing of this fact, as showing the invalidity of any arguments by which it was attempted to associate typhus and typhoid fevers, because the eruption was occasionally absent in these two diseases, and then stated, that in many cases the mulberry rash of typhus, on its first appearance, so closely resembled the rose-spots of typhoid fever, that, to one unused to observe them closely, they might appear, in rare cases, identical; but that his experience, grounded on notes of about 2000 cases of fever, made on the patients' admission into the hospital, and repeated on the subsequent days of their stay, warranted him in asserting, that if any spots, the characters of which were doubtful when seen on or about the eighth day of disease, presented at a later period the characters assigned in his paper, and figured in the wax model as those diagnostic of typhus, then if the patient died, no lesion of Peyer's patches would be found. With reference to the cases alluded to by Dr. Baly, Dr. Jenner remarked, that to be of value in determining the question on which the discussion had turned, *i. e.*, the diagnostic value of the eruption, it was absolutely necessary to confine the remarks to fatal cases examined after death. Dr. Baly had not stated whether such examination had been made with respect to the cases he had seen. With reference to Dr. Crawford's opinion, that the impure nature of the atmosphere of a hospital in which so many cases of fever were accumulated, might account for the dusky nature of the rash in the cases of typhus, and that, probably, difference in the locality in which St. George's and Middlesex Hospitals and the London Fever Hospital were situated, might also aid in accounting for the discrepancy in the opinions of Dr. Jenner and others, he (Dr. Jenner) observed that the latter institution received patients from all localities indiscriminately; from almost every parish in and around London, from Bethnal-green, Holborn, St. Pancras, Marylebone, Kensington, and Fulham; from Greenwich, Clapham, Wandsworth, and Harrow; and that, consequently, locality could not account for the peculiarities observed in the disease; and, moreover, that he (Dr. J.) had visited the houses of the people in very different localities, and could not observe any difference in the hygienic conditions of their inhabitants. As to impurity of atmosphere, those who had visited the fever hospital could not attribute anything to that cause, but those who had not must detect how little force the supposed impurity could have exerted, when they remembered that it was in that hospital, the air of which was *fancied* by Dr. Crawford to be so impure as to convert the rose rash into the mulberry, that such conversion was averred by Dr. Jenner *never* to take place. Dr. Jenner stated, that his observations fully confirmed those of Dr. West, that the ordinary remittent fever of children was really typhoid fever; and that, although several children in the same house occasionally suffered from that disease at the same time, or soon after each other, he (Dr. Jenner) had never seen it give rise in such houses to typhus fever. Dr. Jenner reminded Dr. Stewart, that, in the papers before referred to, he had himself mentioned a fatal case of typhoid fever, in which there was a distinct relapse, accompanied by a second crop of eruption. Dr. Jenner did not consider Dr. Christison having suffered from fever three or four times was any proof that typhus fever recurred in the same individual more frequently than typhoid fever, because that gentleman might have had typhus fever, typhoid fever, and relapsing fever, and as he drew no distinction between them, he would call them all continued fever, and thus might be said to have had fever several times. Dr. Jenner dwelt on the importance of the agreement in the observations of Dr. Gerhard, in America, in 1837; Dr. Shutruck, in London, in 1839; Dr. Stewart, in Glasgow, 1840; and his own in 1849, and referred to Dr. Bartlett's recently published work, in which that author states, that he had seen cases of typhus and typhoid fever lying in Dr. Gerhard's wards in 1847, side by side, each disease marked by its own peculiarities, and added, that the preservation of its own peculiarities by each disease, when side by side in the same ward, was of frequent occurrence, on a large scale, in the London Fever Hospital.

Dr. Stewart begged to be allowed two remarks, notwithstanding the lateness of the hour, in reference to what had fallen from Dr. Crawford. That the peculiar symptoms referred to were not attributable, as Dr. Crawford suggested, to the concentration of the malignant virus was plain, from the experience obtained at the Edinburgh Infirmary. Along with his much lamented friend, Dr. John Reid, who had kindly furnished him with some interesting data for his paper in 1840, he had frequently visited the wards of that hospital, where the fever patients were distributed, as in the Middlesex Hospital, among those labouring under other complaints, and yet precisely the same symptoms presented themselves there as in the Fever Hospital, where, if Dr. Crawford would look in, the next time he was at Islington, he would find as pure air, and as well-aired wards, as in any hospital in London. But there was one observation of Dr. Crawford's that was of the utmost moment—that we should consider fevers not only with regard to time, but with regard to place. Dr. Crawford stated, that he had found no typhus at Munich, but he (Dr. Stewart) when he visited the Hospital at Stuttgart along with Dr. Kiess, found both it and typhoid fever in the wards. At Paris, as Dr. Crawford mentioned, there was never a case to be met with, and when Dr Shuttruck's cases were published in 1840 (only half a dozen), they made quite a sensation in the medical world. And now, there could be no doubt that there was a growing conviction in Paris, that the diseases were essentially distinct. In London, again, there were peculiar facilities for the careful study of this important subject; for, in no two great cities in the world were the numbers of the patients affected with each complaint so nearly equal.

WESTMINSTER MEDICAL SOCIETY.

Dec. 1, 1849.

F. Hird, Esq., President, in the Chair.

ULCERATION AND SLOUGHING OF THE RECTUM.—CONCRETION IN, AND ULCERATION OF THE APPENDIX VERMIFORMIS.—RUPTURE OF THE RIGHT AURICLE OF THE HEART.—ULCERATION OF THE TONGUE, GLOTTIS, AND TRACHEA.—PHTHISIS AND FOREIGN BODY IN THE TRACHEA.—FALLING IN OF THE WALLS OF THE CHEST IN LUNG DISEASES AND HEART AFFECTIONS.

Mr. Canton described the case of an old man, who had recently died in St. Martin's workhouse, exhausted by hæmorrhage. He was of intemperate habits, and, when drunk, used to eat largely of fish, of which he was very fond, and which he used rather to bolt than to eat. Since last February he had repeatedly suffered from hæmorrhage, which was supposed to depend on internal piles, and was treated accordingly. A few days before his decease, a person who was washing him perceived a small dark spicula protruding from the anus, which, on the surgeon's notice being drawn to it, was extracted, and proved to be a fish-bone. Several more were afterwards passed, and at last, the hæmorrhage continuing, the gut was examined by the finger, and more of these fish-bones were removed. The man sunk at last, exhausted by hæmorrhage. After death, a collection of fish-bones was discovered in different parts of the intestinal canal, some buried in fœcal matter, and some sticking in the coats of the intestine. They were of a very dark colour, and were supposed to have been thus deeply tinged by the bile. The rectum was ulcerated to a considerable extent, and sloughing in parts; in two or three places it was completely perforated, and the hæmorrhoidal artery was opened by ulceration. This was supposed to be the source of the hæmorrhage. Mr. Canton considered the case to be one of great rarity

Mr. Marshall exhibited an ulcerated appendix vermiformis, which had caused death by peritonitis.

His patient was a girl about twelve years of age, who had had an attack of vomiting and purging, from which she recovered in two days. A few days afterwards she complained of pain in the abdomen, with bilious vomiting, but no tenderness on pressure. In the evening there was pain in the right iliac region, increased on turning in bed, with tenderness on pressure. Leeches were applied, and relief followed; but the next day the pain had increased, and was general over the abdomen; there was not any anxiety of countenance; pulse accelerated, 100. Twelve leeches were applied, and bled freely; the pain and other symptoms being alleviated in consequence. Turpentine embrocations to the abdomen were also ordered, and Dover's powder, with calomel, given every three hours. The signs of inflammation, however, recurred and continued to increase; the abdomen became tympanitic, and the case ended fatally. The body was examined twenty-six hours after death. The usual results of acute peritonitis were found; the intestines adhering together. On examining the appendix vermiformis, an ulceration was discovered in it, about an inch and a half from the cœcum, large enough to admit a moderate-sized bougie. The opening was jagged and irregular. In the appendix there was found a hard concretion, the size of a hazel-nut, chiefly consisting of fæculent matter, arranged in concentric layers. Mr. Marshall stated, that this was the second case of the same nature he had met with in the last few months. In the other instance, there was also a tumour in the upper part of the thigh.

Mr. Hancock inquired whether there had been any particular hardness in the right iliac fossa?

Mr. Marshall, in reply, stated, that there was neither especial hardness, nor any fulness in that part.

Mr. Hancock had asked the question, because he thought the case somewhat resembled one which he had brought before the Medical Society of London some time ago. He had performed an operation in that instance, and had evacuated the fæcal matter from the abdomen, the patient recovering. He believed it was the only case on record in which such an operation had been performed with success.

Dr. Lankester then brought before the Society the heart of a man, whose case he thus described. He was a carpenter by trade, thirty-four years of age. Had long suffered from palpitations of the heart, and from nervous symptoms, resembling hysteria. He had been a patient in the Pimlico Dispensary. On Saturday night week, while drawing a truck, he suddenly fell down dead. When the body was examined after death, all the viscera of the body were found to be healthy, except the heart, the right side of which was greatly attenuated, so that on being held up against a candle, the light shone through it. There was a rupture in the right auricle to the extent of a shilling in size. According to the history of the case, there had not been any previous inflammatory action, nor was there any atheromatous deposit, nor any indication of ulceration. The rupture, therefore, must have depended on the state of atrophy, in consequence of which, the auricle was unable to resist the action of the heart, its parietes being very thin, and they accordingly gave way. On examining the fibres of the heart under the microscope, no preponderance of fat globules could be detected; but there was evidently a fatty deposit on the external surface of the right ventricle. The muscular fibres of the auricles were less in size than those of the ventricles. He (Dr. L.) had no means of comparing them with the fibres of a healthy human heart, but still he believed that a difference in this respect really existed.

Dr. Ogier Ward mentioned a case which he had seen only a few days before death occurred. The man had been suffering for some time from cough, debility, hoarseness of voice, inability to swallow, &c. There was no striking sign of disease about the chest. The respiration was bronchial in the upper part, vesicular in the lower. On percussion it sounded well. The expectoration was sometimes merely frothy, at others yellow, and like pus. It had ceased when Dr. Ward saw the patient. The man was then apparently dying from inanition and could not swallow even a little water. A strong solution of nitrate of silver was applied to the parts by means of the probang, after which he swallowed some water with facility, and took some nourishment equally well. This was practised on three separate occasions, with similar success, but it was too late; the man sunk. The examination of the body showed an extensive ulcer on the base and root of the tongue, the base of the epiglottis being also involved, thus explaining the severe pain felt in attempts to swallow, as during that process, those parts would be dragged down. The larynx and trachea were also ulcerated, and the lungs were universally affected with tubercle; none of them, however, of any size, being softened. The left lung was emphysematous.

Dr. Routh brought forward a case somewhat resembling the last. The patient was in the third stage of phthisis. A week before death there was difficulty in swallowing, causing violent cough. The patient complained also of a sensation as if there were ball in the throat. After death, there were found great thickening and enlargement of the glottis, with traces of ulceration. One inch down the trachea there was a projection in its paries, which proved to be a piece of bone (since lost), which had caused ulceration and absorption of the cartilage at the part where it rested. How it got there he could not well tell, but it had, in all probability, been swallowed about two years ago. It was about the size of a small pea, and of a jagged appearance.

Dr. Sibson then made the following communication:—

ON THE FALLING IN OF THE WALLS OF THE CHEST DURING INSPIRATION IN SOME DISEASES OF THE CHEST.

Dr. Sibson observed the remarkable phenomena in question for the first time in 1843. A young man aged 34, was admitted into the Nottingham Hospital, under the care of Dr. Hutchinson and Mr. White, labouring under extreme difficulty of breathing. The fauces and glottis were so much narrowed by disease, that only a very small portion indeed of air could enter at each inspiration. The countenance was pale and shrunk, and expressive of distress, anxiety, and starvation. He could only, with difficulty, swallow liquids. The whole chest was narrow and flat, the abdomen prominent. The lungs, though narrow, were much elongated, their inferior margin being more than an inch lower than usual. During each inspiration, all the respiratory efforts were laborious and powerful, but the whole of the sternum, the costal cartilages and ribs, instead of advancing, were actually forced backwards, to the extent, at the lower end of the sternum, of half an inch. At the same time, while the chest shrank inwards, the abdomen protruded considerably and forcibly. Mr. White performed laryngotomy. The air entered freely and the movements of inspiration, so singularly altered, immediately resumed their healthy play. The walls of the chest, instead of yielding inwards, advanced during inspiration; and the respiratory efforts, instead of being ineffectual and laborious, became effectual and easy. At the same time, the chest, formerly narrow and flat, became rounded and full; the lower margins of the lungs, which had been dragged downwards, ascended and resumed their normal position; the countenance, once pallid, shrunk, and anxious, was now ruddy, full, and placid; and the pulse, formerly almost imperceptible, became full and regular. The cause of the remarkable deviation of the respiratory movements in this case was readily apparent. Air could only enter the lungs scantily, and with difficulty; the muscular efforts at respiration were laborious; the diaphragm, acting on the base of each lung, descended forcibly, and lengthened the lungs from above downwards; the lengthened lungs, being inadequately supplied with air became narrower sideways, and the walls of the chest were forced inwards by atmospheric pressure. If a bladder, two-thirds filled with air, be lengthened, its sides collapse, and a piece of wood, resting on the bladder, will fall backwards; if we shorten the bladder, its sides bulge outwards, and the piece of wood supported by them will be pushed forwards. So with the lungs; if they be lengthened when air can scarcely enter them, during the efforts at inspiration their sides collapse, and the walls of the chest in front of them must fall backwards; on the other hand, if they be shortened during the attempts at expiration, their sides will bulge outwards, and the walls of the chest will be forced forwards. Such was the condition and such the chain of phenomena in the case just related,—a case which, in its respiratory conditions, may be readily imitated by any one on his own person. Pass a tape round the chest, close the glottis, and attempt to breathe by the diaphragm; the abdomen will protrude, the circumference of the chest will be narrowed, and its walls will be forced backwards. The action of the diaphragm overbalances the action of the muscles acting on the ribs, not because of the superior strength of that muscle; on the contrary, it is broad and sheet-like, while they are many of them strong and fleshy; nor yet because it acts directly, while they act obliquely; on the contrary, for the fibres of the diaphragm are bent upon themselves in an oblique convexity; their first action is to flatten the convexity, and then, when the fibres are bent almost at a right angle, they draw downwards the floor of the muscle, and so lengthen the lungs. The diaphragm overbalanced the costal muscles and ribs in the case in question, because of the ease with which the lungs can be lengthened from above downwards, gliding, as they each do, freely in an oval cylinder, composed of the costal walls; and, because of the comparative difficulty with which the whole of the walls of the oval cylinder in question can be simultaneously expanded sideways. The point is illustrated by the facility with which the piston of a syringe is raised, even when the mouth of that syringe is closed, and by the complete obstacle which is offered to the elastic expansion of a strong, empty, and closed india-rubber bottle. Since Dr. Sibson observed the case just related, he had noticed the same phenomenon in many cases in which there was obstruction to the entrance of air into the lungs through the large air-passages. He had observed it in cases of croup, of obstruction in the larynx, fauces, and nostrils. The appearance was not alone observed in cases where the obstruction was due to local disease; it was also to be observed, and in an extreme degree in every case in which there was convulsive closure, or great narrowing of the glottis during the struggling effort at inspiration, as in laryngismus stridulus, the first stage of hiccough, the whoop of whooping cough, and the inspiratory convulsions of hysteria. Dr. Sibson had not observed the walls of the chest to be forced backwards during inspiration, under the influence of obstruction in the outer air passages, to so great an extent in any other case as in that just related, and which he brought forward as a type of the phenomenon in question. The extent to which the respiratory movements of the walls of the chest are reversed in such cases is regulated by the amount of obstruction and the flexibility of the costal cartilages. If the obstruction be very great, the whole of the anterior thoracic parietes may be forced backwards during inspiration, the reversed movement being greater at the lower end of the sternum, and less at its upper end. If the obstruction be comparatively slight, the lower end only of the sternum, and the adjoining sixth costal cartilages will yield during inspiration, while the rest of the walls of the chest will, like those of the abdomen, move outwards. If the obstruction to inspiration increase in a case of croup, for instance, the extent to which the respiratory movements are reversed will proportionally increase, and, on the other hand, the extent will diminish as the obstruction to respiration diminishes. An exact measure is thus afforded, by close examination, from time to time, of the phenomenon in question, of the increase or diminution of the obstruction to respiration. If the entrance of air into one of the large bronchi be completely obstructed by the presence of a foreign body, then the walls of the chest will fall in, during inspiration, over that portion of lung supplied with air through the obstructed bronchus. If there be great obstruction to respiration in the smaller bronchial tubes, as in bronchitis, emphysema, and whooping cough, the same effect on the respiratory movements is produced as in cases where the obstruction is in the larger bronchial tube; the walls of the chest fall in. to a greater or less extent, in proportion to the degree of obstruction, and the flexibility of the costal cartilages. The extent to which the respiratory movements are reversed, is in no instance so great, in the cases where the small bronchi are obstructed, as it may be in those where the obstruction is seated in the outer air passages. In emphysema and bronchitis, while the abdomen protrudes, the upper part of the chest invariably expands during inspiration; while the lower end of the sternum, and the adjoining fourth, fifth, sixth, seventh, and eighth ribs may be forced backwards. In cases in which the obstruction is great, all those cartilages, as well as the lower end of the sternum, may fall in during inspiration; but in slighter cases, the yielding may be confined to the

lower end of the sternum. If bronchitis, or any disease in which there is obstruction to respiration in the smaller bronchi, be confined to one lung, or portion of lung, the reversed respiratory movements will be confined to the region of the affected portion of lung. Dr. Sibson had observed the walls of the chest to be forced backwards during inspiration in some cases of effusion into the pleura; the inspiratory descent of the diaphragm in such cases may cause the lengthening, and consequent collapse of the sac containing the fluid. If, in such cases, the effusion be so considerable as to displace the diaphragm to such an extent that it bulges downwards into the abdomen, then, should the diaphragm act, it will be raised, the pleural sac containing the fluid, instead of being lengthened, will be shortened during inspiration, and the walls of the chest, over the seat of the effusion, instead of being forced inwards will be forced outwards. When the whole or a great part of one lung is incapable of expansion, owing to condensation, then the walls of the chest over the affected lung are usually forced inwards during inspiration: in such cases the respiratory movements of the ribs of the opposite side are exaggerated, and the lower end of the sternum is drawn over, at each inspiration, towards the unaffected side; the ribs over the affected lung are in turn drawn over by the sternum, and they consequently fall in during inspiration. In two cases of fracture of the ribs with general emphysema, the side on which the ribs were fractured was indicated by the sinking in of the walls of the chest during each inspiration. When there is extensive effusion into the pericardium, and when the heart is enlarged and adherent, the lower end of the sternum and adjoining left costal cartilages may, in some cases, be forced backwards during inspiration The yielding inwards of the sternum and ribs during inspiration is most marked in those whose cartilages are flexible; it therefore occurs most frequently in children and young persons. Indeed, the inspiratory yielding of the walls of the chest is usually present in healthy infants, especially when they sob; in these the chest flattens during inspiration, the lower end of the sternum receding; but in rickety infants the chest narrows and the sternum protrudes, the parietes being forced inwards at the junction of the ribs to the cartilages. The phenomenon is least marked, or is altogether absent in those whose costal cartilages have become firm or bony; it is consequently seldom observed in the aged. It is very seldom that the four superior or thoracic ribs, or the four inferior or diaphragmatic ribs, fall inwards during inspiration, under the influence of obstructed inspiration; the reversed respiratory movement being usually confined to the lower end of the sternum, and to the fifth, sixth, seventh, and eighth, or intermediate costal cartilages and ribs. When the form of the chest is normal, the lower end of the sternum and the adjoining cartilages present the phenomenon in question, but when the sternum is unusually prominent, the ribs alone are forced inwards, and the sternum protrudes. Dr. Sibson described a case in which, owing to disease of the cervical vertebræ, involving the phrenic nerves, the diaphragm was paralyzed, and in which, while the thoracic parietes advanced, the abdominal parietes shrunk inwards during inspiration; and concluded by referring to the observations of the phenomenon in different instances, made by Haller and Lower; by Dr. Stokes and Dr. Williams in emphysema; and by Dr. G. A. Rees, Dr. Snow, and Mr. Hird in children; and by pointing out the practical value of the sign in question as an auxiliary in the diagnosis of diseases of the chest.

The discussion that followed comprised merely a few questions which were put to Dr. Sibson, the answers to which are embodied in the Report.

CORRESPONDENCE.

THE GENERAL MEDICAL ANNUITY AND RELIEF FUND SOCIETY.

[To the Editor of the Medical Times.]

SIR,—I read with feelings of regret and disappointment the leading article in your Journal of Dec. 1st, on the meeting of the subscribers to Mr. Daniell's Medical Annuity and Relief Fund; and your remarks on the Report of the Committee appointed at a former General Meeting "to inquire into the principles of the Society; to consider the rules and other questions relating to the matter of enrolment; to consult an actuary, if they deem it advisable, and to report to another meeting."

As one of six gentlemen appointed a Sub-committee for these purposes, I trust you will kindly afford me a little space to notice your remarks, which I confess have taken me by surprise, for I did not think that any medical journalist could have been opposed to the *only safe and secure plan* for carrying out a society of so philanthropic and sacred a character. Indeed, I can scarcely believe that the article could have been written by yourself, but by some disappointed person, whose vanity and self-love must have been wounded by the unanimous adoption of a report and plan which so strongly recommended themselves to the whole body of subscribers to whom the document was sent by post, that seventy-six fully approved of it, and only two offered any sort of objection; while at the General Meeting Mr. G. Ross was the sole opposer.

In the leading article Mr. Ross is mentioned as having made "an argumentative speech," and showed that the Report contained *numerous inaccuracies* and *mis-statements*. As to the argumentativeness of the speech, that is quite a matter of opinion; but, judging it by its effects, it seemed to fall powerless on its hearers, and was several times interrupted by the Chairman as very irrelevant. I am not aware of any inaccuracies contained in the Report, though some may have inadvertently crept in, for *humanum est errare*; but to assert that there are *mis-statements* is altogether untrue. Mr. Ross stood alone at the General Meeting, in contending for an institution which should be partly supported by an annual payment of one guinea, and partly by the *charity* of the public, and the richer members of the Profession. Mr. Daniell *has tried* this scheme, and supported it with all the ardour, energy, and disinterestedness for which he is so distinguished, and he has found it wanting. It has utterly failed; for how could a guinea subscription from any number of gentlemen support a superannuation fund for themselves, and supply annuities for their widows and orphans, even though aided by donations, which are always precarious? If Mr. Daniell has failed in his philanthropic and kindly intentioned plan, what other member of our Profession could hope to succeed upon the same principle, except, perhaps, Mr. Ross? Mr. Daniell, with rare magnanimity and singleness of purpose, has abandoned his scheme, which experience has taught him to be *impracticable*, and he has warmly recommended to his friends and subscribers the plan of the Sub-committee. Mr. Ross, with Quixotic chivalry, but doubtless with perfect sincerity and good faith, endeavours to resuscitate a defunct Society, which is repudiated by its founder and the Profession. Why, this is trying to out-Daniell Daniell! Surely a hopeless task.

Was it necessary, then, seriously to combat arguments which every one felt to be useless, irrelevant, and out of date? But, several gentlemen *did reply* to them, and that to the satisfaction of the meeting, though your reporter has been pleased not to notice their speeches. You, however, with the free and easy off-hand editorial style, "presume that these errors and misrepresentations were indefensible!" and you *naively*, but authoritatively add, "that another such Report would ruin the Society." If you mean the old Society, it is ruined already; if you mean the proposed new one, I so entirely differ with you, that I boldly say, (and I have had some experience in these matters,) another such Report and the Society will be firmly established on a sure and solid foundation!

As I cannot suppose that you have read the Report of the Sub-committee, I enclose a copy for your perusal. When you have dispassionately considered it and the excellent letter of Mr. Daniell prefixed, I shall be willing to abide by your own decision as to the course which has been recommended, viz., the abandonment of the old, and the formation of a new and much more extended Society, which shall be founded on sure and safe principles and data—such as can be approved by the most eminent actuaries.

You must remember, that the *outlines* only of a plan have been indicated, out of several which have been considered. Among others, Mr. Hawtayne's, of which and its author you have spoken, I regret to say, unjustly. Mr. Hawtayne has most liberally placed his plan, which must have cost him much time and labour, at the entire disposal of the Committee, and has given much information, which will greatly assist the new Sub-committee, in filling up details, and forming a working scheme, which will, I trust, not only be worthy of, but will receive the support of the whole Profession. I will only further add, at present, that the Sub-committee will gratefully receive any suggestions which may kindly be offered them, whether by the Medical Press, by the subscribers to Mr. Daniell's fund, or by the members of the Profession at large, as the sole object is to form as perfect and as useful an Institution as possible.

I remain, Sir, your obedient humble servant,
Dulwich, 12th Dec., 1849. GEO. WEBSTER.

[There are two or three points in the above letter which we think it necessary to notice. Although exceptions may be taken to the very questionable taste which it evinces, we shall leave that matter to be settled between Dr. Webster and our readers, and we shall limit ourselves to a few remarks on the charges it brings against us in our Editorial capacity. In the first place, we are not opposed to a "safe and secure plan" for carrying out the benevolent object designed by the Committee of the Medical Annuity Society—this would be absurd; but we must wholly dissent from the gratuitous assumption, that the plan adopted is the *only* safe and secure one. This is asking too much from the confidence of the Profession. The plan proposed may be both safe and secure, but will it supply the necessities of those members of the Profession whom we more especially desire to see benefited? Will it, in short, realise Mr. Daniell's original intention? This gentleman himself has expressed his serious doubts upon the matter, and surely we may be permitted, without offence, to doubt also.

Again, Dr. Webster admits that there may be "inaccuracies" in the Report, but denies that there are mis-statements. This appears to us to be a distinction without a difference. An inaccurate statement on a point of fact is a mis-statement; and, although we admitted, that it might be unintentional, that admission does not invalidate the appropriateness of the phrase. In the Report forwarded to us, which was much fuller than that published, we certainly observed, in an exposition of the speech made by Mr. Ross, errors of a very grave character, which, however, from feelings of delicacy, we deemed it advisable not to publish. Dr. Webster has challenged inquiry, and, we think, without much discretion. In all these matters we are resolved to pursue an independent and unbiassed course, and to express our opinions frankly, as they may appear to us to be grounded in truth. Such conduct is more necessary upon this question than almost any other, as it involves pecuniary transactions, and affects our most valued social interests. The policy of the Sub-committee, therefore, is fairly open to criticism, and, for the sake of truth, demands it; and it does not appear to us that it can be satisfactorily defended by incriminations of private individuals. Our zeal in this matter shall not slacken; nay, we are prepared to agitate the subject widely, and to sacrifice much time and labour rather than the cause should fail; but we hold that the first guarantee of success will consist in the appointment of proper persons to responsible duties. The high character of Dr. Forbes, of Mr. Daniell, of Mr. Propert, and other gentlemen, affords the best security that can be desired; but the practical evils will originate in the practical duties of the Society, and here it is that practical men must be found. As we are not aware that any appointments have yet been made, we cannot be considered as unduly reflecting upon any individuals. We hope that such reprehension will never become our duty.—ED. *Medical Times*.]

THE CHOLERA AT TORPOINT.

To the Editor of the Medical Times.

SIR,—As a subscriber of some years' standing to the *Medical Times*, you will, I think, grant me the privilege of a short space in your valuable Journal, more particularly as I know you are ready, at all times, as far as in you lies, to do justice to all parties; and as the subject with which I desire to occupy your columns is one involving justice to others as well as myself, I feel assured you will not refuse my application.

In the *Medical Times* for the 15th December, appeared as an original contribution, and certainly it is an original production—The Cholera—Torpoint, Devon (Cornwall it should be.) It is on Mr. McClure's paper I desire to make a few observations. In the first place, with reference to the sanitary state of the

town, as the resident medical Practitioner, I must say that the picture is overdrawn, and more particularly with regard to the supply and quality of the water, on which much stress is laid. Mr. McClure says, "it is with difficulty that they can procure enough for culinary purposes, and even this is of a deleterious and unwholesome quality. The reader of this would be inclined to imagine that we are very dirty people in the west, and never drink any water, in consequence of a dearth of that great blessing. I have practised here for some years, and never remember a state of things at all corresponding to that detailed by Mr. McClure. The sanitary state of Torpoint altogether, is, I should say, decidedly superior to that of the majority of small towns, and even many large. As a great advocate of sanitary reform, I have often had occasion to feel that there are more difficulties in carrying out its details than perhaps Mr. McClure can possibly conceive, and, therefore, I think his remarks quite out of place. The special object of my writing is with reference to that portion of the paper which relates to the epidemic outbreak of cholera in this place; and here it is that Mr. McClure has (possibly inadvertently) done the greatest injustice to the other assistants who kindly afforded their aid, as well as to myself. Any one reading the statement therein contained must infer, that up to the period when Mr. McClure came among us we were in a perfectly ignorant state, as to the means proper to be adopted at such a moment. Now, was it likely, with all the warnings we had of the approach of the disease, that any medical man could be careless or lukewarm under such circumstances. However, I am sure I shall be able, from facts, to prove quite the contrary. At the first outset of the cholera I worked alone, but soon required assistance, which was kindly and immediately afforded by Mr. Howard Banks, at present Surgeon of H. M. S. Terrible. This gentleman rendered me most valuable service for about three weeks, when his child being taken very ill he was compelled to leave. I then obtained the assistance of Robert Liddell, surgeon, of Bodmin, also a naval surgeon, who was obliged to leave again in a very few days in consequence of a severe attack of diarrhœa. It was at this time I was granted, through the kindness of Captain Joseph Nicholas, the assistance of Messrs. Burder and McClure, but, as the epidemic had abated in virulence, the former gentleman was recalled after a few days; Mr. McClure remained with me. In one part of the report I am said to be unable to attend to my duties. I am thankful to have it in my power to say, that such was not at any time the case, during the prevalence of cholera in this place. The only occasion on which I took any rest by day was for two or three hours on the very day on which Mr. McClure arrived; but that same evening I saw between fifty and sixty patients, and had been up night and day for three weeks or a month, as also had Mr. Banks. I never relinquished my duties during the whole period of the epidemic. The paper in question also states, that the disease went on steadily progressing until the 2nd of September (the day of Mr. McClure's undertaking his duties), when, *mirabile dictu!* from that period it was perfectly manageable; whereas, the fact is, that the disease reached its *maximum* of intensity about August 27th and 28th, and from that date began steadily but decidedly to decline; so much so, that on September 2, the number of deaths had diminished down to about one a day, having been previously five times that number. This can be proved by a reference to the Registrar's book. Every Medical man is also familiar with the fact, that it is one of the characteristics of cholera to go on steadily increasing to a certain point, and then steadily and gradually to decrease. Scarcely any one, I imagine, will be inclined to attribute the disappearance of the disease to Mr. McClure's appearance among us, as would appear from his Report; for he dates the commencement of a return to a better state of things from the very day on which he came here. I can prove that it was considerably before that eventful period. We are further told, in that gentleman's report, that house to house visitation, houses of refuge, and sanitary measures were entirely, or to a great extent, neglected until his arrival. This I consider the most serious charge against me and the other assistants who had acted with me, inasmuch as I think the neglect of such essentials in the treatment of cholera would be highly culpable; but, in reply, I am happy in being able to say, and can prove, that there was no such neglect, and that all the treatment and precautions, to the value of every one of which I am quite alive, inculcated in his paper, were in active operation long before I had the benefit of his assistance. Mr. McClure goes on to say, that twenty-nine people died before he arrived, and only eight after; and upon that at once argues, that it was in consequence of his treatment; whereas, I can prove that not the slightest change in treatment took place; but he does not appear at all to recognise the fact of the decline of the disease before he came among us.

But, even supposing all that the Report says with regard to the Cholera in my poor little town were true, I still think it would be ungenerous in one Medical man to expose the deficiencies of another, even if, by such means, he could in any way advance himself. I certainly should feel great sorrow and regret, if I did not believe and know, that everything that could be done by human agency was done during the whole of the period in which the cholera raged here. I do not write this from any ill-feeling towards Mr. McClure; on the contrary, I shall always feel thankful to him for the assistance he gave; but, in common justice to myself, and those who assisted me, Messrs. Banks, Liddell, and Burder, I cannot allow such statements as Mr. McClure's to remain unanswered. The inference expressed in the Editor's remarks on the paper, is the very one which would be arrived at on reading it, namely, that Mr. McClure had arrested the cholera at Torpoint. I am afraid that we require a more powerful intellect even than Mr. McClure's to arrest cholera; but certain it is, that the cholera had nearly spent itself in our place on his arrival, and that, perhaps, led him into the error of believing he was the means of freeing us from this dreadful scourge. My reply to Mr. McClure's paper I have made as brief as possible, consistently with the circumstances, which, I think, demand quite as much as I have said on the subject, if not more. I cannot conclude this without thanking Captain Joseph Nicholas, the members of our indefatigable Local Committee, and all who so kindly gave their assistance during the late fearful visitation of Providence, to all of whom too much praise cannot be given. I remain, Sir, yours truly,

Charles William Chubb.

Torpoint, Dec. 17, 1849.

MEDICAL LICENSES IN THE ISLAND OF NASSAU.

[To the Editor of the Medical Times.]

Sir,—I received yesterday a file of newspapers from Nassau, New Providence, the chief of the Bahama Islands, of which colony my brother, H. E. John Gregory, Esq., is Governor.

From the *Nassau Guardian* of Wednesday, Oct. 31, 1849, I have extracted the subjoined edict:

"Government Notice.

"His Excellency the Governor has been pleased to direct the names of those gentlemen who have taken out licenses to dispense medicines under the provisions of the Act 9 Vict. c. xx., to be published for general information.

"They are as follows:—

"Mr. Thomas Brace—license dated 26th Sept., 1849.

"Dr. Chipman, } as joint proprietors of Nassau
"Dr. Duncome, } Apothecaries' Hall—license
"Dr. Black, } dated 11th Oct., 1849.

"Dr. Kirkwood—license dated 11th Oct., 1849.

"Any person selling or offering for sale by retail in this island, personally or by any person in his or her behalf, any drug, medicine, or any preparation thereof (calstor oil, the manufacture of this colony only excepted), without having obtained a license for that purpose, is liable under the said Act to be fined any sum not exceeding 20*l.* for every such offence, on conviction before the police or stipendiary magistrate, or two justices of the peace.

"By His Excellency's command,

"F. MacCarthy, Acting Colonial Secretary.

"Colonial Secretary's Office, Nassau,
22nd Oct., 1849."

May I venture to inquire, if you or any of your numerous readers are cognizant of the existence of such an Act as that of the 9th Vict., c. xx., giving to local Governments a control over the dispensers of medicines.

Presuming that the object of such an Act is not the raising of a petty colonial revenue, but a benevolent desire, on the part of the Government, to promote the welfare of the lieges, I beg further to inquire, how it has come to pass, that a similar provision for the inhabitants of the mother-country has not been deemed necessary?

Facilities for procuring poisons have been cleverly shown up by *Punch*, but *Punch* was probably as ignorant as myself, that the Parliament of Great Britain legislates for the Colonies in a different spirit to that in which she legislates for this country.

I am, Sir, your obedient servant,

George Gregory.

6, Camden-square, Camden New Town,
Dec. 11, 1849.

CHOLERA.

[To the Editor of the Medical Times.]

Sir,—Mr. Ebsworth has not yet convinced me of the contagious nature of cholera, as I find the cases in the sequel as inconclusive as those he first published. He states, "The disease broke out in Bellwell, and when it began it had not become universal in the village." I am not aware any epidemic becomes at once universal. It appears, the disease did spread over the village, and, as it broke out epidemically, I would conclude it spread epidemically, as an epidemic, for I do not consider his cases distinct evidences of contagion.

With respect to Mr. Moyles' cases, they are similar to Mr. Ebsworth's, and are open to the same objections. He says: "The disease was brought into his district by John Sandoe, from a place seven miles distant, and communicated to Elijah Here, his son," &c., &c. Who was attacked first he does not say but he visited Sandoe and his son, both lying in a state of collapse at the same time. This savours very much of an epidemic origin; it is unlikely the effects of contagion would have been so rapid. I must inform Mr. Ebsworth, I do not rest my opinions of the non-contagiousness of cholera upon the fact of "six or seven persons in a room with a cholera patient *sometimes* escaping," but on the fact of the cholera *never* having been communicated when the patient has been removed to a locality where the epidemic influences are absent.

With respect to the obfuscated epistle of Dr. Clanny, in your last Number, I must confess I don't quite understand it; he forgets, in his grandiloquence, to tell us "what very painful duty he had to perform," or what was the nature of his important "position;" and then flies off to Dr. Copland's Dictionary as an authority for the endemic nature of cholera. I have not denied its endemic character, and Dr. Clanny ought to have known this, and would have known endemic does not mean contagious, had he not "dismissed from his mind all he had previously read on this subject."

Insipientis est dicere, non putarum.

I am, Sir, your obedient Servant,

Thomas Leithhead.

Warkworth, Dec. 10, 1849.

GLYCERINE.

[To the Editor of the Medical Times.]

Sir,—Glycerine has been of late undergoing the usual course of under-rating and over-rating to which every new remedy is invariably exposed; and as I think the "*contra*" side is now getting rather over strong, I beg to declare myself among the "*pros*," for the good reason that I have used it much, and have found it most serviceable in a number of cases; so much so, that I believe I should be puzzled to find an efficient substitute for it. Such cases are the following:—

1. *Superficial burns*, whether the vesications are broken or not. Used with an equal quantity of water, and applied with a camel's hair brush. It gives great relief, and keeps the part moist for a long time. This is most useful in burns of the face near the eyes, &c., or where dressings on lint, &c., cannot be well used.

2. In *sore nipples*. In these cases it was first recommended, I believe, by Mr. Starlin, in the *Medical Times*, and I have never found any other application nearly so effectual. About one part to six or eight of water succeeds the best.

3. In the *excoriations* in the groins, nates, and behind the ears of infants.

4. In *porrigo favosa and scutulata*, and other skin diseases, but especially in the first-named (when the crusts have been removed by bread-poultices). It should be used as a wash, diluted with eight or ten parts of water. I employ the pitch and sulphur ointment at the same time in these cases; but I do not find the latter so rapidly effectual *alone*.

My actual experience in the use of this remedy goes but little further; but I have no doubt it is very useful in chaps, &c., as Mr. M'Dougal has said, and, indeed, in any of the numerous class of cases where it is an object *to secure moisture of surface, and to protect from exposure to air*. At the least, I cannot consent, at the suggestion of another of your correspondents, to mount a crape hat-band, *as yet*, for glycerine.

I am, Sir, yours very obediently,

Thomas Edward Amyot.

Diss, Norfolk, Dec. 10, 1849.

CHOLERA HONOURS.

[To the Editor of the Medical Times.]

SIR,—I beg to call your attention to the Government's entire neglect of the labours of the Profession in relation to this dread pestilence, and the utter want of provision for the widows and orphans of those worthy men who fell a sacrifice to their courage and devotedness in this perilous service.

Military men are bedecked with stars and ribands to commemorate the glories of blood-shedding and public rapine, and pensions are awarded to the descendants of these honourable man-slayers, lest the country should haply forget the obligation; but who heeds the less dazzling, but more dangerous duties, of the civil surgeon, contending with disease, pestilence, and death, in the filthy alleys of this overcrowded and plague-breeding metropolis? If soldiers and sailors are to be remunerated with titles, rank, decorations, prize-money, and pensions, in consideration of the risk of their lives in the service of the public, is there no reward for us who have stood by our post of duty, and fought a good fight on the field of pestilence—who, better than destroying, have endeavoured to save human lives, and to bring home health, comfort, and joy to ten thousand dwellings—who have neither laid waste nor burned, nor bereaved wives and children of their natural protectors, but have restored many that have been deemed lost, and recovered prosperity with the salvation of life.

Ours was a mission of mercy, and our lives have been risked daily for the benefit of dying thousands. The public has a true instinct of our claims, and would be willing, if it knew how, to acknowledge them. The numerous articles in the public Press testify to the general sense of our services which the public entertain. It is our duty to give a direction to this sympathy, and endeavour to obtain a national recognition of our labours from the Government itself.

I need not refer to the names of Harvey, Hunter, Jenner, unpensioned, and untitled, as instances of a nation's forgetfulness of its benefactors; let us hope that the era that witnessed these things is passing away, and that the genius of destruction is paling her crest before the rising radiance of a purer and a wiser civilization.

I shall be happy, Sir, to form one of a Committee with any gentlemen who may be willing to take up this question, and will communicate with me upon the subject. This will make a beginning.

I am, Sir, yours most truly,

GEORGE ROSS.

24, Farringdon-street, December 10th, 1849.

CREOSOTE IN BURNS AND CHILBLAINS.

[To the Editor of the Medical Times.]

DEAR SIR,—I have had two opportunities of trying the effect of creosote upon burns, in both cases with the most complete success; the first, my own, a severe burn on the back of the hand. The pain was relieved almost instantly.

Supposing that considerable analogy existed between burns and chilblains, I have tried the effect of creosote upon them, in several cases among my children, and in every instance the irritation has been allayed, and an almost miraculous cure has been effected.

I do not know whether this is known to the Medical world; if not, perhaps it may be worth while to notice it in your valuable periodical.

Dear Sir, yours very truly,

W. W. BOREHAM, F.R.A.S.

Haverhill, Dec. 12, 1849.

MOUSTACHED STUDENTS.

[To the Editor of the Medical Times.]

SIR,—I am an old man,—old in years and in practice, dating before 1815. I do not often come to London, but now I am detained here on business; and so, waiting on the "law's delays," and with somewhat of the passion still strong within me, I have visited the London hospitals. Much to my surprise, I observe several students wearing moustaches. May I take the liberty, Mr. Editor, of asking you why such things are allowed? In my time no student would have dared to present himself in the lecture-room so disguised.

I am, Sir, &c.,

SENEX.

[We beg to assure "Senex," that moustaches have their uses; and, among the most important they are considered to point out the idlest, the vainest, and most self-conceited, if not probably the most dissolute in the class. They are beacons to warn others. —ED. *Medical Times.*]

MR. FERGUSSON'S CASE OF EXCISION OF THE HEAD OF THE FEMUR.

[To the Editor of the Medical Times.]

SIR,—About three months since your Journal contained the report of an operation of excision of the head of the femur, by Mr. Fergusson, at King's College Hospital. I have been narrowly watching this case ever since, and as the patient has just been dismissed from the Hospital, I beg to give to your readers an exact account of the condition in which the patient is now in.

In the first place, I may mention that, instead of lying crippled in his bed, sweating at night, and rapidly wasting away, the little fellow has quite recovered his health, and has become much stronger and stouter, and he has been, for the last month or six weeks, in the habit of running about the yard and ward of the Hospital, by means of his crutches.

The following is the condition of the limb itself:—The thigh, measured from the anterior spinous process of the ilium to lower edge of patella, is just one inch and a half shorter than the other, and in its circumference it is about a quarter of an inch larger than the other, and the flesh is much more firm. The following are the movements of the hip:—There is almost perfect power of flexion of the thigh on the pelvis, and, when standing on his sound leg and resting on his crutches, he can swing the limb well backwards and forwards. There is tolerable power of adduction, but the aptitude for rotation outwards is nearly abolished. Whilst using his crutches he can plant his toes pretty firmly on the ground. The whole of the wound is not quite closed, but it is merely superficial, and there is no diseased bone remaining. The patient has been sent down to Brighton for the benefit of the sea air.

Here is an additional instance of one of the triumphs of modern surgery; and as time draws on and we have more experience of this operation, I have little doubt it will be estimated in its proper light. The surgeons of England are already convinced of the use of this proceeding. I know some good and cautious surgeons who are prepared to put the operation in force whenever they get a proper opportunity; and I understand that a surgeon of considerable experience in one of the provinces, influenced by the views propounded by Professor Fergusson and myself, has put the operation in force with admirable success within the last few months, and that a full account is shortly to be published.

I am, yours obediently,

HENRY SMITH.

Caroline-street, Bedford-square.

NECROSIS FROM PHOSPHORUS.

[To the Editor of the Medical Times.]

SIR,—In your Number for November 17th there is an interesting report of a case of necrosis of the lower jaw from exposure to the fumes of phosphorous acid vapour, with a note at the end, mentioning that an analogous disease is produced in the bones of cows exposed to the fumes of arsenic; and this seems to me the more interesting from the fact, as mentioned in Roser and Counderlich's Journal for 1845, that while the cases of necrosis at Vienna (a) came out of many manufactories, those at Nurnberg came from one only, although similar conditions, with respect to the phosphorous acid fumes were present in all, and in that one the possessor made use of Austrian phosphorus, which was ascertained, by Proffessor Dr. Martins, to contain arsenic. Now it seems to me an important fact, to determine whether the phosphorus employed in Britain be so contaminated or not? In the same Journal is a case of a girl seven years old, who, from merely being allowed to play with lucifer matches, amusing herself with lighting them and seeing them glimmer in the dark, got a partial necrosis of the lower jaw; this shows how virulent these fumes are, and how careful people ought to be in preventing children thus dangerously amusing themselves. As it may prove interesting to some of your readers, I add an analysis of the diseased bone from one of the Nurnberg workers, by the Freiherr von Bibra. A is a portion of bone taken by an angular cut out of the left side of the jaw from the foramen mentale; B the new bone upon it; C, a portion of the new grey pumice-stone-like and apparently lavious bone, sawn off behind the foramen mentale towards the linea external obliqua.

	A	B	C
Phosphate of lime	56·80	46·01	45·22
Carbonate	7·25	7·90	5·27
Phosphate of Magnesia	1·42	1·50	2·01
Salts (sol. in water)	0·91	1·50	1·03
Cartilage	32·20	40·87	29·33
Fat	1·42	2 22	7·14
Organic Matter	36·62	43·09	46·47
Inorganic Matter	63·38	56·91	53·53

In a second case, A is a piece of bone, B of osteophyte.

	A	B
Phosphate of Lime	63·02	58·98
Carbonate	3·57	4·05
Phosphate of Magnesia	1·22	1·35
Salts (sol. in water)	0·89	1·00
Cartilage	29·74	30·97
Fat	1·56	3·65
Organic Matter	31·30	34·62
Inorganic Matter	65 70	65·38

Basic salts and free phosphorus were sought for but not found. F. v. Bibra remarks, that in all pathological new formations of bone the organic matter and fat are increased, and that a similar relation of the organic to the inorganic matter is found in most diseased bones. Microscopically examined, the old bone showed enlarged canals, lacunæ, and canaliculæ; the new the same, but larger, and the canals twisted and winding, which F. V. Bibra had already remarked in bones affected by other diseases, as by exostosis, &c.

I remain, Sir, yours respectfully,

Cramond, Dec. 8, 1849. G. W. BALFOUR.

(a) A description of the cases occurring at Vienna and the means adopted by the Austrian Governmen to prevent the recurrence of the disease, was published by me in the *Northern Journal of Medicine* for 1846.

MURDER OF A FRENCH PHYSICIAN.—*La Presse* mentions that a physician, in the department of the Loiret, M. X., aged 66, who had saved 100,000 francs, (4000*l.*,) lately married a third wife, aged 21, on whom he settled all his property by the marriage contract. A few days ago he was found hanging. From the evidence, it was ascertained that he was first strangled and then hung. The police have arrested his wife and a young soldier, whose mistress she was said to be.

HEALTH OF LONDON DURING THE WEEK ENDING DEC. 15.

The past week again exhibits a decrease of the average rate of mortality at this season, and also a decrease on the previous week of 51. The Registrar-General remarks, that the increase of mortality was preceded and accompanied by a decrease of temperature, (the mean having fallen about 16 degrees in three weeks,) and a rise of temperature is now followed by a slight decrease in the total number of deaths. The deaths from diarrhœa number 14, being under the average by 9; and only 1 death from cholera is returned, (in Horace-street, Marylebone,) the average of five autumns being 8. Small Pox, scarlatina, hooping cough, and typhus, are still on the decline; measles, however, show a slight tendency to increase; the deaths from phthisis were 08 against the average of 128, while bronchitis shows 21 over the average. The Registrar of Goswell-street sub-district, reports, that within two weeks he has registered the deaths of three persons 9, Charles-street, Northampton-square, where the family had recently lodged:—first, a young woman of 19, who died of erysipelas (4 days' duration) and of œdema of the glottis, (12 hours;) next week her parents, who were 48 and 47 years of age respectively, and died within 48 hours of each other, the father also of œdema of the glottis, (48 hours,) congestion of the lungs, (24 hours;) and the mother of congestion of the brain, after 48 hours' illness.

It is remarkable, that in the West and North Districts of the Metropolis, which stood most favourably as to cholera, the total deaths are now at about the average of 5 years; whilst in the Central, East, and South Districts, where the fatal epidemic was most virulent, the deaths now stand very considerably under that average,—the decrease in the three Districts amounting to 148.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Dec. 15, 1849.

Causes of Death.	Total	Average of Five Autumns.
All Causes	1002	1162
Specified Causes	998	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	180	307
Sporadic Diseases:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	42	49
Tubercular Diseases	163	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	114	125
Diseases of the Heart and Blood vessels	39	40
Diseases of the Lungs, and of the other Organs of Respiration	219	214
Diseases of the Stomach, Liver, and other Organs of Digestion	61	65
Diseases of the Kidneys, &c . .	14	11
Childbirth, Diseases of the Uterus, &c	7	10
Rheumatism, Diseases of the Bones, Joints &c ...	16	8
Diseases of the Skin, Cellular Tissue, &c.	3	1

MEDICAL NEWS.

Royal College of Surgeons.—The following gentlemen having undergone the necessary examinations for the diploma, were admitted members of the College, at the meeting of the Court of Examiners on the 14th inst.:—Messrs. John Burdett Steward, Birmingham; John Willington Clement, Pocklington, Yorkshire; Charles Augustus James Tompson, St Helen's, Lancashire; Henry Horlock, Newport, Isle of Wight; Crosby Leonard, Bristol; Nathaniel Crisp, Bristol; Edward Akers, Halifax, Yorkshire, Alfred Howse, London; Charles M'Leod Murray, Sudbury, Suffolk, and Daniel Meadows, Witnesham, Suffolk. The following gentlemen were admitted on the 18th inst.—Messrs. Thomas Bolland Powell, Knaresborough, Yorkshire; John Gamm, Hambledon, Hampshire; David Alexander Douglas, Belfast; David Henry Monckton, Brenchley, Kent, Edward Somerset Cleveland, Trichinopoly, Madras; William Bowen Mathias, Dublin; George Hewlett Bailey, London, John Weir Draper Brown, Victualling-yard, Deptford; and Cornelius Hanbury, Stoke Newington

College of Examiners.—At the last meeting of the Council of the Royal College of Surgeons, Mr Cæsar Henry Hawkins, Surgeon to St George's Hospital, was elected a member of the Court of Examiners, in the vacancy occasioned by the decease of Mr John Goldwyer Andrews, of the London Hospital. this election causes a vacancy in the office of Examiner in Surgery at the University of London, hitherto filled by Mr Hawkins The gentlemen appointed Examiners of Candidates for the Fellowship in Mathematics, the Classics, and French, are, we understand, Mr George Gabriel Stokes, M A, Pembroke College, Cambridge, in the former Mr Goldwin Smith, M A, of University College, Oxford, in Classics, and Professor Brasseur, of King's College, London, Examiner in French

Apothecaries' Hall.—Names of Gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to practise, on Thursday, 13th Dec, 1849 — Edward Pinder, Sturley Payne, Bury St Edmund's, Robert Gething, Newport, Monmouth, William Harrison, Bedford.

Obituary.—At Hobshill Cruden, on the 22nd, after a short illness, Dr John Mitchell aged 55 On the 1th of October, at Gorruckpore, W R Glennie, M D H E I C S, formerly of Maybank, Aberdeen

Appointment.—Dr R Chambers has been elected Physician to the Dispensary for Consumption and Diseases of the Chest, Margaret street

Supposed Cholera at Lyons.—The cases resembling cholera that appeared at Lyons have not been followed by serious results For many days past not a single case has occurred, and Lyons still maintains its inviolability

The late Dr. Crowther, of Wakefield, has left nearly the whole of his property, about 10 000*l*, to build an infirmary at Wakefield The erection of this building will not take place for some time, in all probability as his widow and his niece enjoy a life interest in the property It is a noble bequest, but we trust that Dr Crowther has no other near relatives in a state of indigence, as such acts are not always pure benevolence, but done to gain posthumous fame, and where that is effected, to the loss of those who are near in blood, the deed is not so commendable as it may appear to be

We understand that a Royal Commission, for inquiring into the best mode of carrying out the Exhibition of Industry of all Nations, in 1851, will shortly be issued, and is likely to consist of heads of parties and interests, members of the present and late Administrations, representatives of agriculture, art, science, mechanics, and manufactures It is proposed, in addition, to nominate any number of Local Commissioners desirable, to represent all interests, both at home and abroad

TO CORRESPONDENTS

We are sorry that our readers should have had reason to complain of the length of time which occasionally intervened between the appearance of the different papers of the various series, which have lately appeared in our Journal In our new volume we propose, among many other improvements, to continue any papers we may undertake to publish, at least every other week, till the whole series is completed

The friend who writes to us upon the subject of Homœopathy may rest assured that we *do* intend, in an early Number of the Journal,—probably in more than one—seriously to consider this crying evil We quite agree with our Correspondent, that the local and ephemeral pamphlets written on the subject are, in circulation, necessarily circumscribed, and, generally speaking, are not written in a style likely to convince the ignorant amongst the non professional community, nor to strengthen in right principles those of our Profession who are wavering, either on account of doubts raised in their minds through the boldness of speech in assertions of the homœopaths, or, as is more often the case, from the loss of patients,—for there is a rich class of persons who have identified themselves with this species of quackery, and who are running hither and thither to convert others to their opinions, while some practitioners are failing in firmness, and are assuming the form of practising *either way*, according to the wish of the patient!" We are disgusted with the bombastic nonsense which is taken in and retailed by persons in that rank of life which should lead us to hope for better things

"A Member of the College of Twenty-eight Years' Standing," calls our attention to the following paragraph, now going the round of the newspapers —"Royal College of Surgeons.—Mr. * * *, after a severe competition of three days' duration, was admitted, on Thursday week, to the fellowship. There were more than twenty candidates," and, he adds, "there can be no great honour in obtaining the fellowship, when such a disgraceful use is made of it" Upon the same subject another correspondent, who signs himself "One who detests quackery in every form and shape," writes, that the "Illustrated News appears to be the favourite vehicle for the announcement of new appointments, with flaming accounts of the great abilities, and other recommendations of the successful candidates" Our correspondent also alludes to the advertisement we have above quoted, and asks us why Mr * * * should be selected for such especial notice from a list of twenty-one gentlemen, who were admitted fellows upon the same occasion Such proceedings are highly derogatory, and whatever may be the 'grits they bring to the mill," while they do not add to the respectability of the parties even in the public estimation, they most assuredly carry with them the condemnation of the profession

"Mr Jackson's" "Questions" shall receive our early consideration

"Mr J T Tweed's" "Description of the Apparatus for Employing the Mechanical Leech shall appear early in our new Volume"

"Dr Balbirnie" is assured that we have no other rule of conduct than that of right We shall shortly have occasion to review the many works upon the subject of his pamphlet and amongst them we shall not forget 'The Philosophy of Epidemic Cholera"

'Dr Thompson' need not for one moment suppose that English surgeons have any feeling of jealousy towards their brethren in Ireland or of the improvements they originate The paper in question has been long in type, waiting for its turn to occupy our columns

We have received Professor Graham's valuable paper "on a New Property of Gases' We shall keep it for a new year's gift to our readers

"Medicus" is thanked for his remarks on Emigration We will immediately review so very important a subject

We trust Mr Walton and our readers will bear with us yet a little while as regards the 8th Lecture on 'Operative Ophthalmic Surgery' We have much matter in type and at the close of the year, and of our present Volume we are unwilling, pending arrangements for certain improvements to increase our stock on hand

Our friend at Birmingham will we think agree with us that the subject has been sufficiently agitated, and that such shabby conduct cannot by any possibility, again occur,—if not from a sense of honour, from very shame

We will make inquiries concerning the papers referred to by Mr King

We have to acknowledge the receipt of Mr Crouch's interesting letter upon the health of the town of Penzance since the subsidence of the epidemic It is a postscript to a former letter which gave an account of the disease which visited Penzance in 1848, and shall receive early insertion

We hope to pay an early visit to the Royal Polytechnic Institution in Regent's street, and will not fail to inspect Mr J D Hailes universal error globe

"Un Chirurgien" is informed that he will have no difficulty in obtaining what he requires through an insurance office and with the security of two friends To oblige a "Steady Supporter" we will if desired, obtain the particulars.

'Dr Sheridan Muspratt's' Work on the Blowpipe will be reviewed in due course We wish we could treble the size of the Medical Times, and comply with the wishes of all friends at once

We are obliged to the Rev J Barlow for his politeness, and will not fail occasionally to attend the weekly evening meetings of the Royal Institution The Session of 1850 promises a rich and successful harvest, and the Lectures of the Dean of Westminster, Professors Brande, Faraday Cowper E Forbes, A C Ramsey, the Astronomer Royal, Sir R J Murchison, and Messrs Barlow and Cowper, cannot fail to attract numerous audiences

"A Subscriber from the Commencement" asks "Has a member of the College of Surgeons the same right to practise generally as a Licentiate of the Apothecaries' Hall, London and which of the two is the legally qualified practitioner, strictly so speaking?"

[A Member of the College of Surgeons is not legally entitled to practise medicine Yet both the Member and Licentiate are legally qualified, the one to practise Surgery, the other generally]

"Felix" writes —"I shall be greatly obliged by your answering me the following query per your next week's 'Medical Times' Can a medical man obtain damages by law for debts contracted by his patients for medical attendance and medicine, such practitioner not having passed either the examination of the College of Surgeons or the Hall?"—Certainly not

LECTURE XI.

Action of Nitric Acid on Organic Substances.—1. On vegetable matters, as sugar, flour, starch, bread, wood, paper, cloth, the vegetable alkalies alcohol, volatile oils, colours, &c. 2. On animal compounds, as strong albumen, weak albumen, dead mucous membrane, the cuticle, woollen fabrics, &c.—The Tests for Nitric Acid. Its Taste—Action on litmus, on iodide of potassium, on metals, on protosulphate of iron, on indigo, on morphia, brucia, &c—Delicacy of these Tests.—Sources of Fallacy, &c.

We proceed to-day, gentlemen, to consider the changes which take place when aqua fortis is poured upon organic substances; and I may premise by saying, that such substances are readily attacked by nitric acid; and that they are thereby either converted into compounds which contain a considerable proportion of this acid, or of some lower oxide of nitrogen, or else they are still further oxydised and reduced to the state of nitric acid, oxalic acid, or carbonic acid. It has been remarked, moreover, that the very strong acid does not act at ordinary temperatures with anything like so much energy on vegetable matters as the weaker ones do; but of this you will have ample evidence as we proceed.

1. ACTION ON NITRIC ACID ON VEGETABLE MATTERS.

(a) *On Saccharine Substances.*—Scarcely any perceptible change takes place when commercial aqua fortis, however strong it may be, is poured upon white or brown sugar, provided that the temperature of the mixture does not exceed 70° of Fahrenheit. We may even, under these circumstances, keep an acid of sp. gr. 1511 upon sugar for several days, without any notable change being effected. If, however, the temperature of the liquid be raised to the boiling point, a violent re action instantly commences, and copious fumes of nitrous acid, and binoxide of nitrogen are evolved. Acids which have a sp. gr. as low as 1200, act in a similar manner; and a like change takes place, although much more slowly, when we employ an acid whose density is no greater than 1040. In all these cases the carbon and hydrogen of the sugar are oxydised, and the organic substance is more or less completely converted into *oxalic acid*—a fact which may be easily demonstrated by neutralizing the residual liquor with ammonia, and then testing it with lime water; upon which there is formed, as you here perceive, an abundant precipitate of oxalate of lime, a compound which is insoluble in acetic acid. Experiment has proved, moreover, that every 100 parts of sugar will, if they are properly supplied with aqua fortis, yield from 50 to 60 parts of oxalic acid.

Acids which are weaker than the last-named, act, however, in a different manner; for, instead of converting the saccharine substance into oxalic acid, they slowly oxydize the sugar and produce a compound which is known by the name of *saccharic or oxalhydric acid;* this compound is recognised by the brown colour which the liquid assumes upon the addition of ammonia. Still weaker solutions of aqua fortis, as for example those which range between 1012 and 1003, convert the sugar, after long boiling, into a brown, insoluble, crystalline substance, called *sacchulmine.*

(b) *Action of Nitric Acid on Flour, Starch, and Bread.*—An acid of sp. gr. 1151 rapidly dissolves flour, and converts it into a thick, yellow, jelly-like mass; that of sp. gr. 1300 acts in a similar manner, though not quite so quickly; and when the density of the acid is reduced to about 1200, it is necessary to wait ten or fifteen minutes before we can perceive the effect referred to. A weaker acid than the last named does not sensibly affect the farina of wheat, unless it is heated upon the powder, and then it resolves the starch of the flour into oxalic, carbonic, and some other acids which have not yet been thoroughly investigated.

Bread is almost instantly made yellow by acids which have a density at or above 1300; and an acid of sp. gr. 1180 will also stain bread, provided it be allowed to act for twelve hours, during which time, in both cases, the bread acquires a soft gummy consistence.

(c) *Action of the Acid on Wood.*—Ordinary nitric acid always darkens wood where it touches it; but this effect is subject to much variation, not only on account of the strength of the acid employed, but also by reason of the nature and quantity of the resin contained in the wood. In the case of common deal, an acid of sp. gr. 1510 instantly oxydizes the resin and produces a deep greenish brown stain. An acid of sp. gr. 1300 requires about one minute for the production of the effect; that of 1090 acts in about two hours, while an acid having the density of 1010 requires a period of twelve hours for the manifestation of a similar effect. In the case of lignum vitæ, a wood which contains a large proportion of resin, (guaicum,) the nitric acid is acted upon with much energy; for, if we employ an acid of the first-named density, the resin of the wood rapidly decomposes it, appropriates its oxygen, and then red fumes of nitrous acid are copiously evolved, which communicate a bright green colour to the surrounding ligneous tissue. An acid having the density of 1300 instantly produces a green tint with lignum vitæ, and in a few minutes the colour passes on to a deep brown, that of sp. gr. 1180, makes the wood green after an interval of three or four minutes, and in ten minutes the wood acquires a brown colour; even the weak acids, as, for example, those whose densities are not greater than 1040, nor less than 1020, act in a similar manner after an interval of a few hours.

(d) *Action of the Acid on Paper and Linen Cloth.*—Long since Pelouze noticed, that when very strong nitric acid, as, for instance, that of sp. gr. 1500 or upwards, is poured upon paper or linen cloth, it instantly converts the organic substance into a tough parchment-like body, which on being washed and dried is remarkably inflammable, for it takes fire at a temperature of 350° Fahrenheit. Acids which have a density below 1400 do not, however, exert any action upon these fabrics, unless they are heated with them, and then, if the acid be not weaker than 1200 the organic substance slowly dissolves, and, by appropriating oxygen, gives rise to the formation of oxalic and other acids.

(e) *Some of the Vegetable Alkalies* are rendered of a deep red colour by strong nitric acid. This is the case with *morphia*, which instantly assumes a scarlet tint, and effervesces with acids whose densities are above 1300. An acid of sp gr. 1180, acts more slowly on this alkaloid, for it takes a couple of minutes to produce a tint of equal intensity; that of sp. gr. 1090 requires ten minutes for the full manifestation of its action; and an acid having a density of 1040 acts only after an interval of an hour or so. *Brucia* is another alkaloid, which is rendered of a deep carmine tint by aqua fortis; so also are the commercial samples of strychnia, in consequence of their being contaminated with a greater or less proportion of brucia. Many chemists have devoted their attention to the changes which take plac when strong nitric acid is poured upon the last-named vegetable principle, and they have done so because it yields a product which is very analogous to, if not identical with, nitrous ether Here, for example, is a portion of brucia, and if I add to it a small quantity of strong nitric acid, you will notice that it effervesces, and that the evolved gas has the odour of the rennet apple. This circumstance first commanded the attention of Gerhardt, who asserted, that the volatile body was nitrous ether, and notwithstanding that this statement has been denied by Liebig, yet it appears, from the more recent investigations of Rosengarten, Laurent, and Baumert, that the assertion of Gerhardt is correct. Baumert has even shown that other oxydizing agents will, in acting upon brucia, produce a compound which has the character of an alcohol. Moreover, Laurent has examined the red compound which is simultaneously produced, and he has named this compound *cacotheline*, and he states that its composition is $C_{42}, H_{22} N_4, O_{20}$. Lastly, I ought to state, that *narcotine* is an alkaloid, which also has the property of being reddened by nitric acids.

(f) *The alcohols and volatile oils* are likewise readily attacked by strong nitric acid, ordinary alcohol being converted into nitrous ether, and the volatile oils into various brown resinous compounds. The acids which have a density above 1400, act upon alcohol at ordinary temperatures, and, besides yielding the ether just mentioned, they produce many other products, among which are binoxide of nitrogen, nitrous acid, carbonic acid, oxalic acid, formic acid, acetic acid, &c. Even the weaker acids will act upon alcohol, if they are heated therewith. Bromeis, Rabourdin, and others, have occupied themselves by studying the changes which take place when nitric acid is poured upon the commonest of the volatile oils, namely, oil of turpentine; and they state, that when strong aqua fortis is added to this liquid, a violent re action takes place, ammonia, binoxide of nitrogen, nitrous acid, oxalic acid, carbonic acid, and many dark coloured resinous compounds being the products of the change. We may notice, moreover, from what is here going on, that an acid having the density of 1200 will, in the course of two or three hours, darken and resinify this volatile oil.

(g) Finally, I ought to state, that *most vegetable colours* are quickly discharged by strong nitric acid; and if it should happen that the ground of the dyed fabric is composed of an animal product, the stain which is left by the acid usually assumes a deep yellow or brownish yellow colour.

2. ACTION OF NITRIC ACID ON ANIMAL SUBSTANCES.

(a) *On Strong Solutions of Albumen.*—The acid of sp. gr. 1500 instantly coagulates white of egg, and converts it into a deep yellow mass; if the acid be in excess, the coagulum is dissolved with slight effervescence; and on pouring the liquid thus formed into water, it occasions, as you perceive, a copious yellowish white precipitate of nitrate of albumen. Acids which have a density as low as 1100, and which contain about 15 per cent. of dry acid, also have the power of converting the white of egg into a firm yellow mass; but you will remark, that, when we employ an acid of the last-named strength, it requires a few minutes for the production of the full yellow tint. If the acid is diluted so as to have a density of 1020, it still coagulates the albumen; but it must be allowed to act for twenty-four hours before it will become coloured, and even after the expiration of that time the coagulum assumes merely a pale sulphur-yellow tint. Acids which are reduced to the density of 1010 still retain their power of coagulating albumen; but the coagulum is white, not very firm, and it requires a period of ten minutes, and a good deal of the acid liquor in order to be made evident. An acid, which has a sp. gr. of 1006 only acts after the expiration of twenty-four hours.

(b) *Action of the Acid on Weaker Solutions of Albumen*, such as serum of blood, and a liquid, made by mixing the white of one egg with an ounce of water. All the acids down to those which contain 87 per cent. of water, and which have a density of 1090, instantly coagulate the albumen of these solutions, and produce a magma, whose colour varies from deep orange to a pale straw yellow, according to the strength of the acid employed. An acid which has a sp gr of 1020, only produces a white coagulum in these solutions; and when the density of the acid is reduced to 1010, it begins to lose its power of coagulating the albumen.

(c) *The surfaces of dead mucous Membranes* are instantly coagulated by acids which have a density above 1180, and should the acid be much stronger than this, it also stains the tissue of a yellow colour directly the acid is brought into contact therewith; the weaker acid of 1180, however, requires a period of fifteen minutes for the manifestation of this action, and if we employ a solution which contains no more than 14 per cent. of free acid, it

will take twenty-four hours for the production of such a stain.

(d) *The cuticle*, like the more delicate membranes of the body, is also stained by aqua fortis. An acid of sp. gr. 1300 colours it in the course of one minute; and, an acid having the density of 1180 renders it of a faint yellow colour after an interval of three minutes; but a weaker acid has not the power of producing this effect, unless it acts upon the tissue for a long time.

(e) *Action of the Acid on Woollen Fabrics*.—When an acid, with the density of 1500 is poured on a piece of flannel, it instantly decomposes the tissue, evolves fumes of nitrous acid, and leaves a pulpy yellow magma, which rapidly dissolves in an excess of the acid. An acid of sp. gr. 1300 also acts upon this fabric, and produces a deep yellow stain; but the tissue, though rotten, is not so completely disorganized. An acid of sp. gr. 1180 yellows it in the course of one minute, and the stain becomes much deeper in five minutes; that of sp. gr. 1100 requires five minutes for the production of a faint yellow spot; and an acid having the density of 1040 only occasions a faintly yellow tint after the lapse of fifteen minutes.

Now, on reviewing the chemical changes which take place when nitric acid is brought into contact with albuminous substances, we perceive that the weak acids merely coagulate them, and form an insoluble nitrate of albumen; the strong acids, however, exert a more powerful action; for they completely disarrange the molecular constitution of these substances, inasmuch as they render them more or less fragile, and produce a yellow compound, which is known by the name of *xanthoproteic acid*. Very recently, M. Van der Pant has inquired into the nature of the reactions which take place when strong nitric acid is poured on albumen, hair, wool, horn, horse's hoofs, fibrine of muscle, cheese, &c., and he concludes that in all these cases the same compound, namely, xanthoproteic acid, is formed. Mulder, also, has directed his attention to this subject, and, in confirming M. Van des Pant's results, he states that this compound consists of proteine in combination with nitrous acid, and that its formula is 2 (C_{36} H_{26} N_4 O_{12}) + NO_3; it is, therefore, a sub-nitrite of proteine.

THE TESTS FOR NITRIC ACID.

(a). *Its acid taste* is strongly marked, even when the solution does not contain more than three-tenths per cent. of free acid; but when more dilute than this, it gradually becomes indistinct, and when the liquid is diluted so as to contain only one-tenth per cent. of the acid, the sour taste is altogether lost.

(b). *Its faculty of reddening litmus* I have already referred to, and showed that it begins to fail when the solution contains only two-tenths per cent. of free acid.

(c). *Its action on iodide of potassium* is a very delicate test, for as all the commercial samples of aqua fortis contain nitrous acid, they have the power of decomposing this salt and of liberating iodine. This property may be made evident in several ways; we may exhibit it, for example, by dropping a crystal of the iodide into a nitric acid solution; and then, as you here perceive, the liquid becomes yellow, or even red, from the presence of free iodine. Again, it may be made manifest by means of a test paper, impregnated with a little boiled starch and iodide of potassium; such a paper being rendered of a deep blue colour by the acid in question. And with regard to the delicacy of the latter test, I may state that the coloration is very complete when we employ a solution which contains no more than 3 per cent. of free acid. This, however, is not the limit of its delicacy, for a liquid which contains only 1 per cent. of the acid will re-act upon the paper after an interval of a few minutes.

(d). *Its action on the metals* is very peculiar and characteristic, for when nitric acid of ordinary strength is poured upon zinc or copper, the acid is decomposed with the evolution of red fumes, a character which is not exhibited by any other compound. In performing this experiment it is better, perhaps, to make use of the latter metal, which not only has the power of decomposing the acid in the way just mentioned, but it also has the power of communicating to the liquor a deep blue colour, which may be still further heightened by a solution of ammonia. Those liquids which contain about 12 per cent. of free acid do not act very readily on copper at ordinary temperatures; but, if the liquid be heated, red fumes are evolved, even when the solution does not contain more than 7 per cent. of the acid; and, if we note the blue colour produced, we may get evidence of a chemical action when the liquid contains only 2 per cent. of free acid. Relying upon these re-actions, we may show that 50 drops of a liquid, containing 3·5 grains of nitric acid, will give rise to orange coloured fumes when they are heated upon copper filings; and that a similar quantity of fluid, containing only one grain of free acid, will acquire a distinct blue colour under similar circumstances. We may, however, by taking advantage of a discovery made by Priestley, namely, that these orange coloured fumes have the power of communicating a deep olive brown tint to a solution of green vitriol, exhibit the re actions of copper on nitric acid in a still more satisfactory manner; for if we take 50 drops of a liquid which contains only half a grain of this acid, and boil a few grains of copper filings, the evolved vapour will communicate a brown colour to a solution of protosulphate of iron. In order to perceive this re-action under the most favourable circumstances, it is advisable to make use of an apparatus of the following description.

(*a*) A test tube, containing the copper filings and acid liquor.

(*b*) a bent tube, containing four or five drops of a saturated solution of proposulphate of iron. The tube has two enlargements, viz., at *c* and *d*, for the purpose of preventing the iron liquor from being blown out during the operation.

On boiling the liquid in the tube (*a*) its vapour is made to pass through the solution (*b*), and so to produce the brown colouration to which I have referred. It is proper to state, moreover, that the addition of a little oil of vitriol to the liquid contained in the test tube, will favour the result by effecting a more intense colouration.

(*e*) *Its action on a solution of protosulphate of iron or green vitriol* has been still further employed by M. Derbenais de Richmont, who has made it available, in a very ingenious manner, to the recognition of free nitric acid. He takes a portion of the suspected liquid and dilutes it with its own bulk of concentrated sulphuric acid; when the mixture has cooled a little, he carefully adds a small quantity of a saturated solution of green vitriol, taking care that the latter is poured in so as to float on the former. Should the suspected liquid contain nitric acid, a distinct olive brown or pinkish line will appear at the point where the two solutions touch. Derbenais states, that this test is capable of discovering the presence of the 1-21000th of free nitric acid in any liquid; and Jacquelain, who has since inquired into its merits, asserts, that it will detect the one-millionth part of nitric acid in any solution. To show you that it is a very delicate test, I will take 25 minims of a solution which contains six parts of nitric acid in 10,000 of water, and mix them with 20 minims of concentrated sulphuric acid, after which I will add 10 minims of a solution of green vitriol, and in the course of a few minutes an olive brown line will make its appearance along the level where the two liquids touch. Here, therefore, I have made evident the presence of the 15-1000th of a grain of nitric acid; and I make no doubt, from the intensity of the colour produced that I could go still further with the dilution, and still get evidence of the re-action upon which the value of the test depends. It is scarcely necessary, however, in a medico-legal point of view, to proceed beyond this point of dilution.

(f) *The Indigo test*, as it is termed, was suggested by Liebig. It is founded on the property which commercial nitric acid has of decolourising a solution of sulphate of indigo. In performing the experiment, you are to take a portion of the suspected liquid and pour it into about half its bulk of oil of vitriol, which has been coloured blue by a little of the test liquor; in most cases the colour is immediately discharged; sometimes, however, it is necessary to apply heat to the mixture before the bleaching effect is fully manifested. Liebig states that this test is effective when the liquid contains no more than the 4 100th part of nitric acid; and he affirms that, by adding a grain or two of common salt to the suspected liquor, before it is mixed with the oil of vitriol, it is possible to discover the presence of the 5-100th part of nitric acid. But you shall judge for yourselves concerning the delicacy of the test. Here is a liquid which contains 2-10ths per cent. of nitric acid. I will employ 50 minims of it, and add to it 25 minims of the blue sulphuric acid. Upon applying heat, the colour is rapidly discharged, so that I have, by this means, discovered the presence of the one-tenth of a grain of nitric acid. Strong solutions of nitric acid, as, for example, those which have a density above 1300, decolourise the indigo without the application of heat.

(g) *The morphia test* was proposed by Dr. O'Shaughnessy in 1829; and it is dependent on the property which nitric acid possesses of communicating to this alkaloid a deep red tint, which rapidly passes into orange. As I have already said, a solution which contains less than 7 per cent. of real acid, will not, under ordinary circumstances, exhibit this re-action; but, it may be made evident with much weaker solutions, provided we acidulate them with strong oil of vitriol. Here, for example, is a liquid which contains no more than 2-10ths per cent. of free nitric acid; and, if I take twenty minims of such a liquid, and mix it with half its bulk of sulphuric acid, and then introduce a little morphia on the end of a glass rod, you will observe that it instantly produces an orange-yellow tint. If the solution contain a larger proportion of nitric acid, the colouration is still more marked, but it is also more transient; for a liquid which contains no more than 3 per cent. of nitric acid, rapidly decomposes the morphia with effervescence, and produces an almost instantaneous colouration. This test, therefore, offers a ready means of detecting the acid in weak solutions of it; and, as you have just seen, it is capable of discovering the presence of the 4-100th of a grain of nitric acid.

(*h*) *The brucia test*, as it is named, is by far the most delicate of all the tests for free nitric acid. It was advanced by Berthomot in the year 1841, and like the last, it is founded on a property which I have already exhibited to you. Ordinary solutions of nitric acid, will not colour brucia when they are diluted, so as to contain less than 7 per cent. of real acid; but, if we adopt the mode of operating just mentioned, it is possible to detect the acid in extremely dilute solutions. Here, for instance, is a liquid which contains only 1 grain of nitric acid in 300 grains of water, and if I take 20 minims of this liquid, mix it with 10 of oil of vitriol, and then introduce a small portion of brucia, you will notice that a deep rose or carmine tint is instantly produced. We have, therefore, here recognised the presence of a little less than the 7-1000th of a grain of acid. As in the last case, moreover, the colouration is most evident when we employ dilute solutions; for, if we make use of a liquid which contains 3 per cent. of acid, the colouration is for a moment very marked, but it is transient; and, as you will notice, the brucia is decomposed with effervescence. With these evidences before you, you will, doubtless, be surprised to hear the following remark from Mr. Taylor, "According to the same authority (Orfila) the sulphate of brucia is even more sensitive, the alkaloid acquiring a blood-red colour under the same circumstances; but I do not find the result to be so satisfactory. * * The

objections to the test are, that change of colour does not occur with diluted nitric acid."

(i) Other tests have been proposed for the recognition of this alkaloid. Orfila, for instance, states that narcotine is coloured red by this acid. Jacquelin, however, has shown that oil of vitriol will of itself produce a similar effect. Schoenbein states, that a mixture of nitric and sulphuric acids will rapidly oxydise sulphur, and evolve the vapours of sulphurous acid, which are easily recognised by means of paper impregnated with starch and iodic acid. He says also, 'this test will exhibit the presence of one drop of nitric acid in two ounces of oil of vitriol. Again, Mr. Balmain, the assistant of the late Dr. Turner, having noticed that the hydrogen, which is generated in a liquid containing a small portion of nitric acid, burns with a peculiar greenish white flame, has proposed that this character should be employed as a means of detecting nitric acid.

Other chemists have spoken favourably of the gold or aqua regia test, as a means of recognising the presence of this acid; but, however valuable these several re-actions may be in a philosophical point of view, I do not think that they are of any importance to you as medical-jurists; I shall not, therefore, occupy your time by discussing them.

Lastly, before I leave the subject of the tests for nitric acid, I ought to guard you against the *fallacies which are connected with these several re actions.*

In the first place, sulphuric acid frequently contains a notable proportion of nitric acid, and to avoid this, which is a serious source of fallacy, the oil of vitriol must be tested in all cases, before we employ it as a re agent. I may also mention to you, that the presence of nitric acid in oil of vitriol may be easily guarded against, by previously heating the acid with a few grains of sulphur.

Again, it has been noticed, that the chlorates, bromates, and iodates will, under many circumstances, act in a manner precisely similar to the acid in question. This, as has been remarked by Dr. Birkbeck Nevins, is especially the case with regard to morphia and brucia; but, when you bear in mind that these fallacious compounds are not by any means common substances, that they are not at all likely to gain access to the human body, or, in fact, to be found out of the laboratory of the chemist, I think that you will not attach any very great importance to them as sources of error. Independent of this, however, I may tell you, that the fallacy is easily laid bare by the employment of a little oil of vitriol; for, in the case of a chlorate, the salt is turned of a blood red colour, and its solution becomes greenish yellow, evolving an unmistakeable odour of chlorine, when sulphuric acid is added to it; and should we have met with an iodate or bromate in the suspected liquid, it is decomposed when it is heated with oil of vitriol, and liberates the fumes of iodine or bromine, which cannot well be mistaken.

ORIGINAL CONTRIBUTIONS.

ON CHOLERA.

By WILLIAM HALL, M.D.,
Late Physician to the English Embassy to the Court of Persia.

It appears to me, that the great diversity of opinion regarding the nature and treatment of cholera arises from the Profession not being agreed as to the meaning of terms; from not defining exactly what we mean by cholera, and what is essential to constitute the disease, and also from not sufficiently distinguishing between two most opposite conditions of the system, viz., the active resistance opposed by the powers of life to the cause of disease which we term fever and inflammation, as contrasted with that paralysed condition of the circulation, and complete yielding of the vital powers to the morbific agency, which we observe in cholera. The object of my Lectures was, to inquire whether anything peculiar is invariably manifested in every one of the different forms that Asiatic cholera assumes, such as we might consider to be essential; and this inquiry seemed to show, that there is one thing constant, and without which no disease can justly be regarded as cholera, however varied the other symptoms, viz., loss or diminution of those vital properties of the capillary circulation by which the blood is preserved fluid, and prevented from adhering to the interior of blood-vessels,—by which those re-actions between the blood and tissues are performed which are necessary to life, and of which the evolution of animal heat is one important result.

In genuine, unmixed cholera, this want of vital action in the smaller blood-vessels was pointed to as the first effect of the epidemic influence on the body, both in point of time and importance, and as preceding every other symptom. The effect of this condition of the vessels of the extremities is contraction of the veins, which causes an exudation of cold fluid on the skin, and forces the blood into the great interior veins of the chest and abdomen, whence it cannot return, on account of the valves of the exterior veins; but the same state of the vessels exists in the lungs, which prevents the blood being purified by sufficient contact with the air, and is furnished to the body by the arteries in small quantity, and in a condition unfit long to maintain life. Being thus forced inwards from the limbs, and prevented passing through the lungs with freedom, the blood accumulates in the great veins, and would choke the action of the heart, if it did not find vent somewhere; but these veins, being without valves, allow it to be forced back to their terminations on the intestines, and there, when pressed by the continued influx, its more fluid parts are gradually filtered through the membranes, and then gush from the bowels in a sudden torrent of serous purging. The evacuations are without bile, because the circulation through the liver, by which bile is secreted, is stopped or reversed; and no urine is secreted, because blood is unable to pass through the vessels of the kidneys in opposition to this retrograde force. Such was considered to be the condition presented by pure primary or congestive cholera; but of this we have had comparatively few cases here,—for hitherto the influence of cholera has not often been sufficiently powerful to produce its pure effects, till the powers of life have been previously reduced by another cause presently to be mentioned. Still, a few cases of this nature occasionally present themselves, and the symptoms are, perfectly clean, pale, and cold tongue; hands and feet cold and damp, and the nails blue, before or along with the first purging,—if, indeed, purging or vomiting occur at all, which are often wanting in this form; the urine ceases from the first; there is pain and oppression, and intolerance of pressure, at the pit of the stomach; cramps in the belly and legs; a peculiar struggling action of the heart; and, if there be purging and vomiting, it is copious, and of fluid resembling water in which rice has been boiled, inodorous, or only smelling faintly like blood. In such cases, I have never yet found the treatment by quinine and iron, bloodletting, &c., recommended in my Lectures, fail, if used before the feet had become warm while the body remained cold. But the disease which is at present so fatal throughout the country, is not, once in a hundred cases, of this unmixed congestive character. It is either, in the first instance, epidemic dysentery, which is variously called English cholera, or autumnal diarrhœa, a non-contagious malady; or it is the same disease in combination with putrid fever, which is most virulently contagious, and well known as the putrid dysentery of our cellar-population, which sometimes takes the place of putrid fever when epidemic dysentery prevails. Now, the occult causes, atmospheric or other, by which those distinct diseases, epidemic dysentery and epidemic cholera, are produced, unfortunately, co exist at *present* in the country; of these, the cause of dysentery has, of late, been more universal and more powerful than that of cholera, attacking the population violently, in many places, without any case of collapse,—that is, cessation of vital action in the blood-vessels,—following; and in most places where cholera has appeared this autumn, the dysentery has preceded it by two or three weeks, without being followed by collapse. During the last four years, when we were free from cholera, the same disease has paid us an annual visit; last year, and the year before, very severely, without any of the cases lapsing into cholera. The weekly Bills of Mortality are themselves evidence, that diarrhœa, though, to a certain degree, premonitory, is not a stage of cholera; otherwise, how could so many die without becoming subject to collapse? We can conceive *recovery* from an incipient stage, but not *death*, without the actual access of the disease. But, when the cause of cholera exists along with that of dysentery, no sooner is a person attacked with purging, and his strength is thereby reduced, than the vital powers that had previously sufficed to resist the effect of the choleraic influence, yield to it, and the patient falls into collapse; the active condition of the vessels that exists in acute dysentery then stops, and more or less complete cessation of vital action takes place in all the smaller vessels. If, then, dysentery, in its simple, non-contagious form, is capable of producing this effect, much more will this be the case, when it is combined with a cause so opposed to life as putrefaction. Careful study and inquiry, both here and elsewhere, have so convinced me, that this combination of epidemic with putrid disease has been by far the most frequent forerunner of fatal cholera this autumn, that I have no hesitation in stating my belief, that almost every case reported as cholera, which has occurred in the purlieus of our towns, ill-drained houses, crowded lodgings, schools, and poor-houses, has been of this nature, before collapse began. The symptoms are as follows:—

Easy vomiting and purging (without much griping) of watery mucous fluid, slightly tinged with bile, and of a decidedly putrid odour, differing much in appearance, but still more in smell, from the true rice-water exudation—each motion is accompanied with passage of urine, the tongue is red, warm, and furred in the centre, the extremities warm, and the nails, though dark coloured, as in hepatic affections, are brownish, rather than of the blue colour observed in congestive cholera after the commencement of purging. When this has gone on for some time, it may be an hour or two, without one symptom which any one conversant with the congestive form of disease would recognise as cholera, a change occurs, for as yet it has not been cholera, but really the reverse, being a state of greatly increased activity of the secreting vessels of the intestines, instead of cessation of secretion—an excitement of their vital action that in every respect resembles that produced by the absorption of croton oil or jalap, resulting in active purging of watery mucous secretions instead of passive serous exudations. This very soon reduces the vital powers almost to syncope, and then the superimposition of cholera may be seen most marked, by commencing in the extremities. The limbs become cold, blue, and like wet leather to the touch, urine ceases to be secreted, and the discharges, though they retain much of their putrid odour, lose their excrementitious smell, and become serous instead of mucous, but the breathing is almost natural, and there is none of the struggling action in the heart remarkable in congestive cholera, because the sudden change from over excitement to loss of action in the vessels of the intestines, appears so complete as to render them incapable of opposing any resistance to the revulsion of the blood, now driven into them from the extremities. The fluid of this blood is drained off so readily into the bowels, that no congestion or distension of the veins takes place sufficient to disturb and excite the action of the heart, secretion passes almost instantaneously into exudation, and the discharges run in an almost constant stream into the bed-cloths. Such is the collapse which succeeds putrid dysentery. As there is little congestion, the cramps are slight and little painful.* The feet of the patient, sunk in this hopeless state, begin to become warm long before death, which, in the congestive disease, seldom occurs more than twenty minutes before the final struggle. By-and bye, decided warmth is perceived in the hams; the arms then lose much of their chilly.

moisture, sudden slight convulsion ensues, and the patient is dead. The body only slightly regains its warmth after death, whereas, after congestive cholera it becomes almost as warm an hour after dissolution as the natural healthy skin in life. The cause of death in the two cases is different —in the one the patient dies asphyxiated from want of arterial, and the circulation of venous blood in the system; and from overpowering congestion of the great veins and vital organs, this often terminates in fearful convulsions. In the other, death results more from general loss of blood, or, what is the same thing, of its fluids, and from consequent gradual exhaustion. It is evident, if the two conditions here described, both of which are termed cholera, differ so essentially, that the treatment must equally differ. In the primary disease, to relieve congestion, and restore the powers of the blood vessels, is the great object in attempting cure. In that which succeeds to dysentery there is no congestion to relieve; instead of blood filling the great veins almost to bursting, and the heart struggling with an oppressive load of blood, its action is here feeble and hæmorrhagic, and the body is so rapidly drained of its vital current that the power of reaction is generally gone by the time the collapse begins. In the first the purging is a mechanical effect and a natural mode of relief to congestion, and ceases as soon as congestion has been relieved and the circulation restored; but, in the other, purging is the principal part of the disease, and if the patient be restored from the condition of collapse thus induced, the dysentery renews its course, and is only changed again from passive exudation to its former activity of secretion. Instead, then, of exerting ourselves to excite the activity of the capillary circulation in the dysentery which leads on to cholera, we must employ every means in our power to subdue excessive action, lest the powers of life should be so reduced by this active overpurging as to bring the system under the influence of the cause of cholera. This compound disease, then, must be treated as dysentery, wholly independently of its tendency to terminate in cholera, and this must be pursued as far as possible, even after collapse has commenced; for should we succeed in rousing the patient from collapse the previous active purging returns along with restoration of the functions of the vessels. The treatment that has appeared to me the most effectual in producing the desired effect int his disease, has been the frequent repetition of emetics of ipecac. and tartar emetic, or a large dose of calomel mixed with a grain of tartar emetic, aided by frequent injections of acetate of lead and opium, sinapisms, warmth, &c., and constant persistence in the use of emetics is the only means by which I have seen patients permanently recovered from the stage of decided collapse in this form of the disease. I am inclined to believe that bilious disorder is the cause of the almost universally prevailing diarrhœa produced by some effect of the epidemic cause upon the liver; the motions remain long clay-coloured in almost all affected, whether severely or slightly, until restored to a more natural condition by a smart mercurial purge or alterative treatment; and with regard to the treatment of acute dysentery, I have met with no essay so practically excellent as that contained in Mr. Twining's work on the "Diseases of Bengal." According to my experience, the appearance of the tongue affords the most unerring signs of the treatment to be pursued, and the most useful symptoms in distinguishing how far diarrhœa depends on dysenteric irritation, or on venous congestion. If cholera be in the neighbourhood, and the tongue be clean, pale, and bloodless, cessation of diarrhœa and uneasiness will almost invariably follow the administration of a few drops of muriated tincture of iron, and two grains of quinine; but if the tongue be red, it will be attended with the opposite effect. When simple dysentery merges into collapse, the tongue often becomes quite clean and pale, and the chalybeate is then highly necessary to begin with; but if some pale mucus or fur remain attached to the centre of the tongue during the collapse, and it be not quite bloodless, we may be pretty confident that we shall find the evacuations putrid; and no advantage is to be expected from the chalybeate in that case. To conclude, I would state it as my opinion, that the cases of primary Asiatic cholera have of late been comparatively rare; that the disease so prevalent since the beginning of August has been a species of English cholera or Dysentery, dependent on disorder of the bilious secretions, which are thus rendered drastically purgative instead of gently aperient, as in health; that this is frequently united with the causes of putrid dysentery or fever; in other words, with the effects which putrid particles, absorbed into the blood, produce on the fluids of the body; but more especially on the intestinal mucus altered by dysentery; that the disease then becomes much aggravated, the symptoms such as have been described above, and highly contagious; that epidemic dysentery, with or without this putrid character, exists generally throughout the country, whereas the cause of epidemic cholera is not so universally spread; but that where the two co-exist, the former acts as a powerful predisponent to the latter; that previous to August, the cause of cholera existed in many places, independently of that of dysentery, and frequently produced the true primary disease; but that since that period, the great majority of cases of collapse have been induced by the predisposing dysenteric derangement, without which the cause would have been insufficient to produce its effects on any large proportion of the population. Now, with regard to the fungous animalculæ, and other popular theories, these appear to me all effects of a pervading cause, whatever that may be, which is generally observed to attend the presence of cholera,—viz., a greatly increased tendency to every kind of decomposition of organic matters. This was noticed in Mr. Whitbread's brewery, in 1833, during the week that cholera was at its height in London; for porter then fermented in a third less time than usual. Putrefaction in water increases the production of fungi sporules and animalculæ, and I am inclined to believe that the evacuations of cholera patients in which the sporules described have been discovered, have been from those labouring under the putrid form of disease above described, and not from the primary disease, or even from those in whom collapse was preceded by simple dysentery. There exist, I think, good reasons for believing that active putrid particles applied to the mucus of the intestines in life, especially if altered in its character by dysentery, are capable of very rapidly converting that mucus to the state of a putrid irritant, and that, in fact, these theories of the cause of cholera are the result of a very common error,—that of mistaking physical effects for causes.

Manchester, October, 1849.

CONTINENTAL MEDICINE.

By Dr. KIDD.

(Continued.)

The late fearful plague having now entirely disappeared from France and Germany, men begin to look back at the abysm over which they have, as it were, by a miracle escaped. Every one, too, has his own experiences to relate, his own grain of sand to add to the mountain of opinion growing up, so that here, as well as in England, it is a matter of no little difficulty to get at any leading or general principles. In the matter of treatment our French friends, too, have been quite as much at fault; and on the simple subject of contagiousness or the opposite, no two people can be got to agree.

The appaling mortality of the disease here has been more than once pointed out. Taking at hazard one of the last returns, we find that of 10,752 attacked, 5,937 had died! The lowest rate of mortality has been this dreadful 50 per cent. that I pointed out before in Ireland. In one of the immense establishments I visited, *Salpetrière*, with its labyrinth of wards and old people, it amounted to 76 per cent., and in many of the other hospitals it was scarcely less destructive. The total numbers have been yet scarcely well ascertained; when they do, they will add, no doubt, an additional puzzle to the already desperate array of statistics which is every day furnished us.

Some India reports of the former so-called dreadful epidemic of 1830, in that country, contrast curiously with figures at home at present. The army in India, according to Annesley, were attacked in the following proportion:—Of Europeans, 2287 were attacked, of whom only 425 died—something about 18 per cent. Of natives (and these figures are nearly the same as the Paris ones that I have accidentally just taken), 10,885, of which 2986 died, only 27 per cent. In Russia there were about the same period 3590 cases, 865 deaths, in all a manifest smaller rate of mortality than in the late visitation.

With these figures, let us compare this frightful 76 *per cent.* in one of the best-managed Hospitals in Paris, with the results in Russia during the late epidemic,—at St. Petersburgh, 17,742 cases, 10,138 deaths; remaining sick, 1986; mortality, *about 57 per cent.* At Moscow, 9754 cases, 4309 deaths —something the same. In Moldavia, 10,000 persons died; almost every one seized. In several other places it is scarcely necessary to cite, the same wide and wasting destruction of life occurring. I have been reading De Foe's account of the plague in London; the scenes lately in the parts of Paris rendered classic by Victor Hugo and Eugene Sue, where Fleur de Marie and Esmeralda plied their miserable trades, the streets about Notre Dame excelled, if possible, in multiplied horrors, this dreadful recital, 700 dying by the day; every one almost seized. Paris, in fact, like what we read it was in the Middle Ages.

Whether this increased mortality may be one of those things that, like Tubercle or Cancer, follow in the wake of civilized life, is, perhaps, a question of no little interest to determine; or that, like Variola and cognate affections with which Cholera has been of late, with no little show of reason, associated, the virus of the disease may not undergo changes in character, from assimilation of other morbid products, is more than doubtful. The entire question is one of the most difficult that can present itself to the mind. We must not, however, give it up in despair. Facts and observations crowd on us on every side. A dreadful battle has been fought, the smoke now clears away, and its history must be written.

The comparison of the Cholera in the year just passed and that in '32 has been so often made, we may, perhaps, rest satisfied with the fact, that this time it has been more fatal. In the former visitation, 31,000 died in England and Scotland; in '49, already nearly 50,000. In 1832, in London, 5275 were taken off; in the present year, need I say, nearly three times that number. We are too fond, perhaps, of going back for hideous tales, and tracing the destroying influence to the swampy marshes of the Ganges,—to 1817, when it sprung into new life in India,—to 1793, when it arose among the pilgrims of Hurdwar,—and back still further, into the questionable twilight of antiquity,—neglecting the facts before us, and those appalling lessons which the past twelve months have revealed. Twenty thousand of those about us in London swept away; twenty thousand in Paris; the ever-increasing tide of population for once turned back; the mortality in the swampy, low-lying districts on the South side of the Thames actually three times that on the North,—two-thirds of this appalling number, therefore, due to ourselves.

Of the essential nature of the disease, of course, as well as its communicability, opinions in every possible way vary on the Continent. The blood and various secretions have been examined over and over again; our imaginative neighbours are wont to represent the different secretions as merely the prismatic changes of the blood; and if the latter be really disordered, as Dr. Stevens would have it, that changes in the secretions, rice-water discharges, &c., are merely secondary phenomena,—that if the wonderful physiological life of the blood is at an end, the drain away of its watery parts into the intestine, and the coagulation of its fibrine in the larger vessels about the heart, are merely necessary consequences, that all our attention should of course be directed towards the disease in its earlier stages, and that when this change takes place in the vital current, all is over; though tinged a little with the good old dynamism

of Stahl (our friends on the Continent are ever among their musty chronicles), this opinion perhaps, as much as any other, brings us towards the true road for studying the disease. That the contagious or non-contagious character of the malady may depend on the character of the different *excreta* thrown off from the body will appear also not so impossible. That an epidemic constitution of the atmosphere is at work at the same time, overlying, as it were, in its results, these and the ordinary phenomena of contagion, is also not to be forgotten; indeed, the majority of the phenomena of cholera-diffusion point to this perhaps alone; hence the errors we have been led into.

As in England, numberless observations in France point to the non-contagiousness of the disease, in the ordinary sense of the term, to its arising from a particular specific constitution of the atmosphere, which M. Andraud and others still think of an electrical character, and its fearful increase in the rate of those attacked, according as the epidemic wave passes along. About the 5th of June last, when cholera was in its zenith in Paris, the diminution of the electricity of the atmosphere was quite remarkable; on the 7th totally gone. This, Andraud says, was the turning of the tide! On the 8th a storm occurred; the electricity of the atmosphere was restored, and went on increasing.

I am quite aware of Quetelet's observations on this subject; and if, as he states, and states truly, the electricity of the atmosphere is ordinarily three times as energetic in January as June; more marked in a strong and clear sky, and almost always of a positive kind, it does not lead at once to the conclusion, that these changes have nothing whatever to do with the disease in question; that there is some connexion, not yet understood or studied, there can be little doubt. What it is will, perhaps, dawn on us, like the truth about contagion, after patient and diligent research. The dynamic electricity of the needle too—who would have thought it?—differs from this static electricity of the atmosphere, so that we must, in all researches of the kind, go to work correctly.

Some curious facts, in opposition to the old opinion, that the disease is due to telluric influences and cannot arise, for instance, at sea, have been observed in France; and, if not coincidences are exceedingly interesting. A vessel left Havre for New York—no cholera at the former. When she was 15 days at sea it broke out. Another vessel left a little after, and when she got to the same latitude and longitude the same thing occurred—the two vessels coming into the same *equally infecting* condition of atmosphere—we want a word—*iso-endemic*, perhaps. The two vessels, under the same predisposing conditions, with a contingent of wretched German and French emigrants on board happening to meet the epidemic wave travelling from Europe to the New World, or, increased in power, coming from the land. As to this epidemic wave, indeed, there is no doubt. In India, I need scarcely say, when the disease first appeared it spread with terrific rapidity *up* the Ganges, and could be traced *up* the Jumna without crossing either; it was never known to go across the tops of the high hills forming the boundaries of the catchment-basin of these immense rivers, in its thirteen years travelling to England; it could be observed, day by day, getting along, as a general rule, in the same way, in the route of the most populous districts, along rivers and valleys, giving some false countenance to the opinion of contagion. In France and Germany, with one or two apparent exceptions, the same thing has occurred. In Hanover, for instance, we are told, the people escaped; though, when I was there some time since, they seemed as intent on their bad sausages and sour wines as ever. This yet remains to be inquired into.

The examination of the secretions in cholera—a thing about which one would think there could be no difference of opinion, has exercised the ingenuity of the chemists of both countries. The characters of the discharge from the kidneys, for instance, has created considerable discussion in Paris. From the total inversion of the process—its complete suspension in many cases—this is not to be wondered at. The presence of phosphates and oxalates in the bowels, was not wanted to tell the practitioner how much at fault this essential part of the economy is, in common with the rest of the splanchnic arrangement. As to the presence of *albumen*, Bouchet one time found it in 23 cases, Levy in not less than 50, at La Pitie. Becquerel also detected it, and this while the *extractive* products of the blood were also increased. In no other way can we account for those appalling cases every one has seen, where the surface becomes blue,—the pulse at the wrist, as I have often felt it, like a vessel filled with air,—a true "artery," undulating under the finger,—the venous system evidently gorged by a clot in some large vessel,—the entire vitality of the blood, as it were, annihilated. *Fibrine*, too, has been found, and *fatty matters*,—everything, in fact, that ordinarily finds its way into the circulation, without the power, in this instance, of getting out again; its vitality destroyed; the functions of the glands of the abdomen at an end,—the whole arrangement of the solar plexus, in fact, diseased.

Simon and Heller found the urine in cholera patients thick, sedimentous, acid, with a sp. gravity ranging between 1·011 and 1·018, with the important change of nearly an entire absence of urea. This, too, perhaps, is not difficult to account for, when we remember the elements of this latter body form themselves in the capillary system, and are further combined in the kidney, whose organic nerves are also incapable of performing their normal function. Wittstock found the urine pale—neuter; sp. gravity 1·008, with ammoniaco magnesian phosphates; and Vogel of the same density, acid, the sulphates in excess, the other salts deficient. The specimens operated on in these instances, I am inclined to think, were not from true cholera patients.

The results arrived at differ very little, perhaps, from those in England; those of Garrod and those of Parkes, for instance, except what our neighbours call coagulated albumen, we call fibrine and mucus. In all such analyses it strikes me, however, *quantity* is the main point, as I believe the true organic character of the blood is destroyed.

Of the exact proportion of those seized with the disease that recovered, perhaps the return from Bartholomew's is a fair exponent: 478 cases were received; 279 recovered. Cases of relapse have been much more frequent, too, than in the East. Indeed, so generally has this character of the disease been observed, that there are not wanting those who look upon it as a fever of a very bad type, of a remittent character, increased by malarious influences. Some men in France look on the Plague of the 14th century as one of the first visits of the disease; others, as not contagious, but strictly infectious; while many would seem to think it one of those frightful things we shall never understand,—a disease beginning, as I think Majendie once said, where all other diseases end—*with death*.

PROGRESS OF MEDICAL SCIENCE.

FRANCE.

(From our Paris Correspondent.)

IS TYPHOID FEVER CONTAGIOUS?

The highly important Papers on typhoid and typhus fever, from the pen of Dr. Jenner, which have recently appeared in your Journal, have attracted much attention here, where typhoid fever is so frequently the subject of debate. The Academy of Medicine had made the "contagious or non-contagious nature" of this disease, the subject of one of its annual prizes, and received seventeen competing Memoirs, which were submitted to a Committee composed of Louis Chomel, Bricheteau, and Gaultier. Of these seventeen Memoirs, four were in favour of non-contagion, thirteen for contagion; and this latter opinion is that of the Commission. It is remarkable that the school of Broussais, once so flourishing in this country, had only a single representative amongst the candidates. As a follower of the *gastro-enterite* theory, he, of course, was a non-contagionist.

Laying aside the etymological signification of the term "*contagiare*," the authors of the different memoirs recognize a contagious element in every possible mode of the transmission of typhoid fever from one individual to another. Thus, while they prove by indubitable examples that an individual labouring under typhoid may communicate the disease to others in a locality where the fever did not previously exist, they regard it necessary that a deleterious atmosphere, capable of infecting those constantly exposed to it, should be formed round the individual who propagates the disease.

The Academy, at its last meeting, appointed M. Bricheteau President, and M. Orfila Vice-President, for the ensuing year.

CONTRACTILITY OF THE SPLEEN.

Some interesting experiments on this subject have been recently performed by the Biological Society, at the request of M. Rayer.

From the researches of M. Kolliker, and, before him, of many other physiologists, we know that muscular tissue is composed of a series of elongated cellules, with an elongated nucleus running parallel to that of the cellule. The same Author has also described this arrangement in many organs, or parts of organs, where muscular tissue had not been thought to exist. He has found them, for example, in the nipple and its areola,—in the arteries, veins, lymphatics, in the Fallopian tubes, in the spleen, &c. Now, if these cellules were really of a muscular nature, it is evident that they must be contractile. M. Wagner has submitted this to the test of experiment, and found that the spleen contracted, evidently under the influence of galvanism. Indeed, M. Defermon had previously directed attention to the singular contortions of this organ produced by strychnine. The experiments performed at the suggestion of M. Royer, and relative to this interesting question, were made on dogs. One of these animals was poisoned with strychnine, the spleen having been first exposed. The organ was carefully measured, and, when the convulsions appeared, it was measured again. The volume of the organ was very slightly diminished,—not more so than might be accounted for by difference of circulation; but the surface of the organ had evidently undergone a remarkable change. It was crisped, and the edges had assumed another form. This experiment was not very conclusive. The spleen of another dog was, therefore, exposed and measured, after which a strong electrical current was directed on it. After a few minutes the long diameter had diminished by two or three centimetres. The experiment was repeated several times with the same results. On passing the current *across* the organ, its transverse diameter became diminished. The pedicle of the spleen was now cut across, and it was suspended by its larger end from one of the conductors of the machine. On applying the other wire, which was done more than twenty times, the spleen was seen to ascend, and to become twisted in the most evident manner.

ALBUMINARIA CURED BY CHOLERA.

The theory of expelling one disease by another is at least as old as the days of Horace, but has not many supporters in modern times; least of all did we expect to derive this benefit from the cholera. M. Martin-Solon, however, has met with some curious examples at the Hôtel Dieu. A boy, sixteen years of age, had scarlatina on the 21st of June, 1849. The disease was light, and convalescence rapid, but anasarca showed itself, and soon gained both the chest and abdomen. There was very little fever, but the urine was surcharged with albumen. On the 6th of August the patient was attacked by cholera, which continued rather violent for two days. The diarrhœa was peculiarly severe on the 8th, when the dropsical symptoms had completely disappeared. On the 9th the choleric symptoms abated, and those of albuminaria recommenced; but they were trifling, disappeared rapidly, and the patient soon left the hospital cured of both his complaints.

In another case, where the disease was idiopathic, and no ways connected with scarlatina, the cholera effected a cure equally complete and rapid.

GERMANY.

[From our Berlin Correspondent.]

CHLOROFORM.

A death from chloroform lately occurred in Berlin, and made a great sensation. A young lady died two days after an unsuccessful attempt had been made to extract a tooth while under anæsthetic influence,—the re-action, it is said, operating upon the brain. The dentist has been examined before the judicial authorities, and charged with having administered the drug without the presence of a surgeon or physician, as required by law,—not that such authorization would have saved the patient; but "the law allows it, and the Court awards;" and the effect will be to check the indiscriminate and indiscreet use of chloroform, which is here as fashionable as it seems to be in your northern capital. It has also given rise to many discussions among scientific men. Langenbeck, the successor of Dieffenbach in the University Clinic, and formerly Professor at Kiel, has availed himself of the opportunity to publish his "experiences" on the matter. He has used chloroform in all ages,—in the child of a few hours old, and in patients of 80 years of age. He has had but one death from it, and that in a sailor with comminuted fracture of the ankle, requiring amputation. While tying the artery, Langenbeck observed black blood and gas bubbles issuing from the wound, and the patient died half an hour after the operation. The same occurrence also lately took place in La Charite, during the operation for excision of the lower jaw. On dissection, much black and frothy blood was found in the right heart. By the way, Professor Baumgartner announces some illustrations of the cure of diseases of the respiratory organs by chloroform.

ABSENCE OF THE UTERUS.

A complete absence of the uterus has lately been found in a woman four years married. She had never menstruated; had a chlorotic countenance; her breasts swelled periodically, and she had sexual sensations. The vagina terminated in a *cul de sac*. A catheter passed into the bladder could be felt by the rectum.

THE DIRECTION OF LA CHARITE

was, until lately, in the hands of one of the Professors; but the last medical director having placed objectionable persons in subordinate situations, the Government have taken the appointment to themselves. It is now vacant, and will not be given to a medical man.

MEDICAL REFORM

meets with much opposition, even in the Profession. The papers by Dr. Bushnan in the *Medical Times* have fully explained our system of medical polity; and now the lower grade of surgeons, fearing to be in a worse plight than its members already are, are petitioning Government strongly on the subject.

SCOTLAND.

[From our Edinburgh Correspondent.]

The third meeting of the Edinburgh Medico-Chirurgical Society took place on Wednesday, Dec. 19; Mr. Syme, the President, in the chair. This being one of the meetings devoted to the exhibition of pathological specimens, Professor Simpson showed an example of extensive

TUBERCLE IN THE FALLOPIAN TUBE.

The person from whose body the preparation was obtained had been confined in an Asylum, for some time before death, on account of insanity. The disease was originally acute mania, she was the mother of several children, and had continued to menstruate to the last. A conversation ensued, which turned chiefly on the rarity of tubercle in the uterus and Fallopian tube. Dr. Bennett said, however, that he had met with several instances of tubercle affecting the Fallopian tube. Some remarks were afterwards made on the continuance of menstruation, notwithstanding the complete obstruction of the Fallopian tube by the tubercle; but this admitted of explanation, as the tube of the opposite side might be still pervious. Mr. Goodsir remarked on the singular fact recently observed in a female cut off by a violent death during menstruation, that the Fallopian tubes were filled with blood, or, at least, with a bloody fluid, different from the menstrual fluid.

CANCER OF THE LIVER.

Dr. Bennett then exhibited a liver studded with cancerous nodules, one of which, the size of an orange, formed a prominence which, when the liver was in situ, lay exactly over the region of the pylorus. The man from whom this liver was taken had been received, a short time before, into one of the clinical wards of the Royal Infirmary; and his chief symptoms being vomiting of blood, particularly after taking food, some impediment to deglutition, the aspect of organic disease, and the existence of a hard round tumour exactly on the region of the pylorus, the case was regarded as one of scirrhus of the pylorus. There was, besides, dulness, with crepitation, on the left side of the chest, which led to the belief that there was pulmonic inflammation on that side. The patient stated, that he had been stout and healthy during his past life, and that he had not suffered from ill health till about four months before he entered the Hospital. The *post-mortem* appearances here were highly instructive. The hard tumour felt in the region of the pylorus was, as already noticed, in the liver, exactly over the pylorus; the pylorus did not exhibit the characters of scirrhus, but it was strictured by a simple thickening; there was an aneurism of the aorta, and this was the source of the blood which was believed to come from the stomach. The left pleura was full of blood, derived from the aneurism, and the blood had also oozed into the left lung, so as to give rise to the crepitus which had been remarked during life. There was scirrhus in the œsophagus, accounting for the impediment to deglutition. The scirrhus also affected the peritonæum. Dr. Bennett stated, that he had observed, on several previous occasions, how different the diagnosis was between inflammation of the lung and the existence of blood in the pulmonic tissue, derived from an adjacent aneurism.

TUBERCLE OF THE CEREBELLUM.

Dr. Bennett exhibited next a cerebellum, containing a tubercle the size of a walnut. The man from whose body this was taken was a drunkard, who had died of fever, with much delirium, and there were appearances of subarachnoid inflammation; but these were manifestly recent, and had no connexion with the tubercle in the cerebellum. What rendered the case remarkable, was the existence of a cicatrised tubercular cavity at the apex of each lung, the origin of which was probably coeval with that of the tubercle in the cerebellum. This man was between thirty and forty years of age, but no satisfactory account of the circumstances of his previous life had been obtained.

MR. SYME ON CERTAIN TUMOURS.

The President then exhibited two tumours which he had recently removed. One of these belonged to that description of tumour which is recurrent, being the third which had been removed from the same person in the same region of the body. Mr. Syme called the attention of the Society to this kind of tumour, as one which presented important difficulties in practice, there being no certain diagnostics of its presence except the result of an operation, notwithstanding that when its character is known an operation is improper, as the morbid process is thereby accelerated. The tumour is white, and has somewhat the aspect of a fibrous tumour, but, at the same time, approaches more or less to the adipose formation. At first, no pain attends this kind of tumour, and the patient's health remains unaffected. It is easily removed by operation, and the wound heals even rapidly. But soon after the wound closes, another tumour, or, more frequently, a groupe of tumours, of the same description, appears in its seat or in the neighbourhood. If these be also removed, new productions take place, marked by a degeneration of character. These excite pain, undergo fungous ulceration, and, in the end, prove fatal. Mr. Syme referred to a paper on tumours of this kind, by Dr. Douglas Maclagan in the *Edinburgh Medical and Surgical Journal*, for July, 1837, and noticed several cases besides, which had lately been communicated to him. Mr. Syme, in his "Principles of Surgery," describes this kind of tumour as differing from the adipose formation only in having a slight admixture of cellular substance; and this coincides with what Vogel says of fatty tumours in his Pathological Anatomy. The example he gives of fatty tumours occurred in a woman forty years of age, who had been operated on four times, owing to the continual re-appearance of the tumours. "They were composed," he says, "of fibres identical with those of ordinary areolar tissue and of fat cells, which corresponded exactly with those observed in common adipose tissue.

Some conversation took place, also, on the structure of the second tumour exhibited by Mr. Syme. Dr. Bennett was disposed to regard it as of a fibrinous character. He complained that the microscope had been too little used in the discrimination of the structure of tumours.

THE CHOLERA BODIES.

Dr. William Robertson showed, under the microscope, specimens of the alleged cholera bodies which had been transmitted to him from Bristol.

NEW SURGICAL HOSPITAL.

The managers of our Infirmary have just determined to build a new Surgical Hospital. It is to occupy a portion of the space between the south end of the present Surgical Hospital and Drummond street, and the main entrance will finally be in Drummond street. It is to be of the form of a T, the part corresponding to the horizontal line being parallel to the old city wall bounding Drummond-street, that corresponding to the upright line running north and south in the same direction with the present Surgical Hospital. This Hospital will be commenced immediately, and will be completed in about a year; and then there is an intention of building a wing to the east of the present Medical house, which will form the commencement of an entirely new Medical Hospital, the rest of which may be gradually built on the site of the present Hospital, the whole front being towards Drummond-street.

SELECTIONS FROM FOREIGN JOURNALS.

ON THE USE OF DIURETICS IN THE TREATMENT OF LIENTERY, AND OF EVERY FORM OF FLUX FROM THE BOWELS.

By Dr. HELIN.

It is in general against diarrhœa, depending on excessive secretion of the mucous follicles of the intestines, that the Author advises diuretics. This method of cure, in so far as lientery is particularly concerned, rests on an observation, too largely generalised, we conceive, by M. Helin, that the arrestment of an intestinal flux by astringents or by opiates, is followed, in certain cases, by ascites, and, if the latter begins to subside, the diarrhœa returns. In promoting the secretion of urine, in directing the fluids from their unnatural tendency towards the intestinal canal, the diarrhœa and ascites disappear simultaneously.

The routine of treatment consists in the exhibition of the nitrate of potassa, from five to twenty or thirty grains, with a third of a grain to two grains of squill powder, in some suitable vehicle. To obedient subjects, he gives these, along with mucilaginous potions. No tonics, no astringents, no opiates. If the patients refuse the medicines, or the intestines do not well bear them, the endermic system is put into practice.

The Author asserts, that the use of diuretics checks the evacuations in typhoid fever, and he suggests their use in dysentery.—*Journ. de Méd. et Chir., publicé par la Soc. des Sciences Méd. de Bruxelles.*

THE CELL PENITENTIARY SYSTEM.

M. de Castelnau has concluded his Memoir, entitled, "Reflections, Moral and Hygienic, on the Peniten-

tiary Cell System, and on Systems of Punishments generally."

The leading conclusions of this extended work are as follows:—

1. Contrary to what has been generally asserted by all public writers who have interested themselves in the matter of Penitentiary Reform, the number of criminals has not increased in France these twenty years. The proportion of the number of criminals to that of the population has been the following during the four periods of the twenty last years:—

From 1826 to 1830 1 culprit for 4511 persons.
1831 to 1835 1 .... 4429 "
1836 to 1840 1 .... 4296 "
1841 to 1845 1 .... 4898 "

2. The number of culprits has continued thus as invariable as that of the crimes.

3. The proportion of second offences has equally been the same in 1845 as in 1826.

Such are the fundamental facts which M. Castelnau has laboured to establish in the first portion of his dissertation on the Criminal Population of France.

In the second part, he has considered the agency of the cell system on the health and intellectual powers of the prisoners.

After showing, that the statistical documents collected from the cell prisons of the United States are neither sufficient in number nor in authenticity to be a basis for positive conclusions,—after having proved, that, even though those documents were sufficient, and of proper authenticity, they could not, however, be collated with those procured from other establishments, situated in different localities, as the mortality might, and does actually, vary much among prisoners under the same regime; but, in establishments at a great distance from each other, M. Castelnau offers demonstration by the accompanying illustration of this curious fact.

In the central prison at Poissy, (Seine et Oise,) the mean mortality for seven years (1837—1843) has been 3·82 in 100; in the central prison of Eysses, (Lot et Garonne,) under precisely the same *régime* the mortality has been, for the same period, 13 for 100.

On comparing the mean mortality of the young prisoners of the Department of the Seine, one portion of whom (the young men) are under the cell system; and the other portion (the young females) are under the common plan; the annexed results are obtained:—

Mean mortality under the common plan 5·37 in 100
Mean mortality under the cell system 10·50 in 100

These conclusions, which M. de Castelnau considers only as showing a strong probability in favour of the common regime, in consequence of the imperfect state of the figures they rest on, are furthermore corroborated by the most acknowledged principles of physiology,—principles which would be quite adequate of themselves, as M. de Castelnau is persuaded, to prove *à priori*, the excellence of the common system over the cell system, in a hygienic point of view. These principles are, that the health of man, as that of all other animals, will be proportionally more perfect, in so far as it can more completely exercise all its functions, and satisfy all its wants. And it is enough to contrast for one instant the mode of life the prisoners lead, to perceive that those who live under the cell system are in a condition most unfavourable to health.

Entering on the third question which he had proposed to investigate, to determine the utility of the regime of the cell system, as affecting the question of morality, M. de Castelnau corroborates, by the following propositions, which are the simple ratio of numbers, that it is absolutely null and void.

In Pennsylvania, the frequency of crime is precisely the same since the institution of the cell system as it was previously. The same holds true in Paris.

In conclusion, M. de Castelnau conceives generally the futility of every system of ameliorating the condition of prisoners; for the amount of criminalty, he remarks to be as determined as that of the fall of bodies. It is apparent, then, that it is less our object to correct criminals, than to place them in a position where they can do no injury, and may contribute to the general service of society. This M. de Castelnau conceives is to be accomplished by improving the condition of the prisoner.—*Academie de Médecin et Gazette Médicale.*

INFLUENCE OF THE NERVOUS SYSTEM ON THE PULSE—PREDOMINATING ON ONE SIDE OF THE BODY.

The operation of the nervous system on the pulse is, to some extent, one-sided; irritation applied below the decussation of the anterior pyramids of the medulla oblongata, chiefly influences the same side, while applied above this point, or to the brain, it chiefly affects the opposite side.

In the first of these cases, pain or paralysis causes a diminished speed of the pulse and capillary system; while a less considerable irritation—which mainly affects the motor part of the nervous system—or an increased movement of the body, accelerates the pulse.

This is shown, (1) by experiments on frogs. If the webs of the two hind feet be, at once subjected to microscopic examination, and one of the fore feet be nipped, it will be seen that the pain induces a dilatation of the vessels, and a diminished speed of the current, in both the hind feet; but that the retardation is much more considerable on the corresponding side. If the muscular irritability of one side be weakened by passing a continuous current of electricity lengthwise through the hinder extremity, the current is retarded on this side, accelerated on the other. Cutting through the anterior columns of the spinal cord, causes extraordinary retardation of the capillary circulation of the same side, attended with dilatation of the vessels. Light blows on the chest or belly, especially in the region of the hinder lymph-heart, quicken the circulation and narrow the vessels on both sides, but most on the irritated side.

(2.) In man, moderate movement of one foot, while in the sitting position, quickens the radial pulse on the same side. Pain, mechanically excited in the ulnar nerve of one side, retards the pulse on both sides, but most on the irritated side. Withdrawal of the stimulus of light from one eye, as well as total or partial paralysis of one side of the brain, retards the pulse on the opposite side, while continuous reading with one eye, the other being freely exposed to the light, quickens it.—(H. Horn, *N. Med.-Chir. Zeitung*, No. 31, 1848. Abridged in *Schmidt's Jahrbucher*, No. 10, 1849.)

SOFTENING OF AN ANTERIOR LOBE OF THE BRAIN WITH LOSS OF SPEECH.

This case was a very uncomplicated one, and served strongly to support Bouillaud's opinion. A man, aged 32, who had received a trifling injury to the foot, was suddenly taken with vertigo, inability to articulate a single word, and hemiplegia and loss of sensation of the right side. Consciousness remained. On the third day power began to be regained over the leg; the arm remained paralysed. On the fifth day he passed urine spontaneously; previously it had been retained. On the eighth day, after a shivering fit, he died. The anterior third of the left hemisphere was softened, and of a milky white colour. The softening affected only the medullary substance. —M. Rizzi, in *Gazetta Medica Lombarda.*

ONE CAUSE OF STERILITY IN THE FEMALE.

For more than nineteen years M. Vannoni has been engaged in the study of this subject. He believes that an original want of development of the body and neck of the uterus is the cause of sterility in many women. Examination per vaginam discovers a small hard neck, a minute opening, and on pressing down the body of the uterus with the hand placed externally, it also appears small. In these cases the sexual desire is usually very slight. A cure is not impossible; sometimes after many years of married life, the uterus gradually enlarges, the neck becomes more voluminous, the os more open; then impregnation may occur. Vannoni thinks, that if this will not occur, after marriage, without remedies, no cure is to be hoped for.—*Il Progresso* (a new Journal, published bi-monthly at Florence.)

INTERMITTENT HÆMATURIA.

A case of quotidian ague, in which, after the shivering, a violent pain came on regularly in the loins and hypogastric region, and was succeeded by passage of a small quantity of thick and bloody urine, has been reported by M. Defer, of Metz. The case was cured by sulphate of quinine. A similar case occurred to Elliotson.—*Gaz. Med.*, Nov. 17.

NEW METHOD OF DIAGNOSTICATING BILIARY CALCULI.

In a case of jaundice, M. Martin-Solon, found that on pressing the hand below the region of the gall bladder, and, on directing the patient to make two or three expulsive and inspiratory efforts, he could feel the gall bladder impinge on the fingers, and could perceive a sort of crepitus produced by the friction of the gall-stones on each other. The crepitus could be perceived also by the stethoscope.—(*L'Union Med.*, Nov. 15.)

CHOLERA AT THE SALPETRIERE.

A very interesting account of the severe outbreak of cholera at the Salpêtrière is given by M. Barth in the *Archives Générales* for September. We can offer only a short analysis. At the commencement of the attack there were 1571 insane and epileptic patients, 3287 old, infirm, and blind patients, and 483 servants and persons employed in the place. On the 14th March the first case occurred, on the 19th the second; on the 20th there were 10 new cases, and the number, with little variation, increased from this number up to 58, on the 3rd of April; the disease remained at its height till the 10th of April; it then gradually declined, till, on the 25th, it was considered at an end. Persons of all classes in the place were attacked, but the numbers are not given. In 5 per cent. the cholera commenced suddenly; in all the other cases by diarrhœa, which usually lasted from one to eight days. In 117 patients, in whom the onset of the disease was noted, in one, cramps first appeared; in two, vomitings; in all the rest purging was the first symptom. Purging, at some period of the case, was present in all the cases; vomiting was absent in 10 per cent.; cramps in 3 per cent.; coldness of the body was absent in 3 out of 169, or 1·7 per cent. Cyanosis was marked in almost all the fatal cases, being absent once in 30 patients; among the recoveries, it was absent 1 in 18. In 90 per cent., the pulse was diminished, and in severe cases abolished. In 91 patients, the urine was suppressed in 70, was retarded in the rest. The coldness of the body was often more marked to the hand than the thermometer. In one case, M. Roger marked 31 Cent. (87·8 Fahr.) in the axilla. Sometimes there were oscillations in the malady, or remissions in the symptoms; very rarely intermissions. The greater number of deaths occurred in the algide period. Re action was a salutary condition when it remained moderate, and constituted a happy transition towards the cure; but when it passed certain limits, it gave rise to new accidents,—congestion of the brain and the lungs. One fourth of the fatal cases died in this stage. In only two cases, out of the whole number of re-action, was there an eruption; in one case it resembled measles, in the other a diffuse papulo-erythema. In six other cases there was diptheritic deposit on the tongue and in the cavity of the mouth. Eight cases of the recoveries had relapses. In 30 of 162 fatal cases, the duration of the disease was less than twenty-four hours; in 58, one day; in 28, before two days; in 14, the end of the third day; only 32 lived beyond the third day. Among the cases of recovery, some were out of danger on the third day, but in the greatest number of cases it was from the fourth to the seventh before convalescence was established. Age exerted a great influence on the mortality; in patients from 10 to 20 years, the mortality was 10 per cent.; from 21 to 40 years, 30 per cent.; from 41 to 60 years, 61·54 per cent.; from 61 to 90 years, 79 88 per cent. Nothing new is stated respecting the *post-mortem* appearances. The treatment was various. The "hachisch" (hemp) failed; the sea-salt was more successful, but not very much so; the use of the nitrate of silver was followed by much more satisfactory results. This medicine was at first given as an enema; afterwards by the mouth; the doses were five centigrammes gr. ¾) in two or three ounces of water. It seemed to arrest the stools and to moderate also the cramps.

TO SUBSCRIBERS.

New Subscribers will oblige by forwarding their Names direct to the Office, 147, Strand, or to the News Agents or Booksellers. All Post-office Orders should be made payable to the Publishers, Wm. S. Orr and Co.

The present Number closes Vol. XX. Next week we intend publishing a very copious Index.

We shall also, next week, avail ourselves of the first Number of our Twenty-first Volume, to offer Addresses to our Readers, both from ourselves and from the Proprietors of the "Medical Times."

THE MEDICAL TIMES.

SATURDAY, DECEMBER 29, 1849.

We have reason to be satisfied with the identity of opinion that now exists between ourselves and other representatives of the Profession's interests, upon the subject of the proposed alteration of the Charter of the College of Surgeons. We have not written in vain; for we have produced conviction in a quarter where it was least expected. This is the privilege of truth. It is now obvious that the resolution passed by the Council of the College is too trivial to meet the exigencies of the crisis; and that if the time is come to apply to the Government for a new Charter, it must be to obtain powers of a far more extended and comprehensive character than those contemplated in the Resolution. Let us revolve a few ideas upon this matter. What will the College do? What can they do? What do we require?

The entire history of the conduct of the Council of the College of Surgeons is opposed to the idea, that they will ever willingly consent to such an alteration of the Charter of the College as shall constitute it the legal home of the General Practitioners. We commence with this observation, because the propositions of Mr. Bottomley, as submitted to the President of the College at the recent interview, contemplated such a result. These Propositions, in their general bearing and aim, must command approval, as there cannot be two opinions upon the expediency of making the College of Surgeons the head of the surgical and medical practice of this country, so far as concerns the General Practitioners: the only ground of doubt is its practicability. If such a scheme should ever be seriously entertained by practical men, it would involve the necessity of abolishing the Apothecaries' Society, of providing for its Licentiates within the walls of the College, and of giving a status and legal rights to the Graduates of Scotch and Irish Universities practising as General Practitioners in this country.

It would be idle to attempt to re-constitute the Profession upon a basis less extensive than this. No Government would condescend to examine such propositions,—no really authoritative association would accept them; the Practitioners from Scotland and Ireland would clamour for equal rights, and justly condemn English selfishness; and the Apothecaries' Society, urged on by their Licentiates, would obstruct every such imbecile attempt, by interposing the immoveable wall of an Act of Parliament. Partial legislation would, therefore, be equally imprudent and unjust, and is, in point of fact, entirely beyond the question.

Is the governing body of the College of Surgeons prepared for this issue? We unhesitatingly declare that it is not. The Fellows and the Council are equally opposed to it; and the former not less, but rather more, than the latter. Each Government that has been applied to has also undisguisedly declared its repugnance to such a consummation; in fact, the disposition hitherto has been to retain the College of Surgeons as a special Institution on a similar footing with the College of Physicians, as such an arrangement is considered to be more in harmony with the spirit and principles of past legislation, and with the public Institutions of the country. We know that there are absurd fallacies in these notions, and that a thorough propounder of abstract truths would be able, in a few sentences, to shatter the whole of these hoary prejudices. But politics is not an abstraction, and philosophical dogmas occasionally look very defenceless and puerile before hard interests and time-honoured customs. The truth is, statesmen must deal with things as they are, and not as they might be, and they must always bear in mind, that what is frequently belauded as justice is not always equity.

If, again, to take a wider view, the College of Surgeons be constituted the sole Medical Institution in this part of the country, the powers of the College of Physicians must be abrogated, together with those of the Apothecaries' Society; and would these bodies consent to be thus unceremoniously wiped out of the calendar? or would their licentiates and fellows surrender without a struggle their peculiar privileges and honours? It is a reform, and not a revolution, that is wanted.

Whilst we see countless difficulties in the way of such a reconstitution of the College of Surgeons as many Members of the College seem to desire, we are of opinion, that the Members will obtain a much wider enfranchisement in the College than they now possess, if they agitate boldly and steadily for this object. Let them not, however, think that the Council is at present disposed to grant such liberal terms to the Members as they demand. There is not one Member of the Council that is prepared to grant a ten years' franchise; if there be, let him speak out, that his sense and liberality may be duly honoured. Mr. Guthrie himself has repeatedly declared, that he is in favour only of a twenty years' franchise, which, in fact, constitutes the pith of that egregious penal resolution lately passed by the Council, and once eulogised as an act of gracious condescension to the demands of the aggrieved Members. It is a little dust thrown out to blind the eyes of unwary Members—nothing more. Mr. Guthrie has also declared, that he is favourable to the formation of a Board within the College, to examine candidates in Medicine and Midwifery; but he makes it a condition that these Examiners shall not be eligible for the Council. This is a proposition to cast odium upon the highest branches of professional science,—upon, indeed, the very Science itself. It means, that the Science of Medicine shall be dishonoured, degraded, insulted, and ostracised in the College of Surgeons, in order that the Council may be preserved in all its original purity. We repudiate these terms, and hold them up to the gaze of the Profession, so that they may incur its severest animadversion. Can we ever consent that the Examiners in Medicine and Midwifery in the College of Surgeons shall be of a lower dignity than the Examiners in Surgery and Anatomy, and dwarfed down to the same standard of insignificance with the Examiners in French and Mathematics, whom the Council has recently appointed? The Council has, and may again degrade the Members who are also Practitioners of Medicine, but the Science—never! These schemes will never be tolerated, and yet these are the best that the most liberal Member of the Council has to offer.

The Members must depend upon their own strength, and proceed with the agitation of sound and reasonable reforms. It is not easy to say what or how much would satisfy the numerous varieties of opinion that prevail; but, unless the Profession can unite upon some general scheme, which shall embrace not only the Members of the College or the Licentiates of the Hall, but all classes in a common interest and object, we fear that their efforts will be as ineffectual as the flapping of a bat's wing against a church-steeple. Union alone can make them strong, and they can be united only upon a common interest. Any policy that introduces jealousy, exclusion, preferences, must make enemies; and even if suffered, can only be regarded as means to a more just and enlightened system, by which all men equal in point of social station and Professional acquirements shall be equal also in the eye of the law.

OUR SANITARY LAWS.

London is the ordeal and the touchstone of Sanitary Reform. If Sanitary Reform can be carried out here in the face of selfish property, opposing interests, and an immense population, its success is assured everywhere. In answer to the question, How are we to set about Sanitary Reform? we may propose another, How is the health of the poor inhabitants of London to be improved? The answer to the second supplies an answer to the first demand, and that answer we shall now attempt to give.

The greatest danger the cause of Sanitary Reform has ever encountered exists now. At this very moment, when all seems won, failure is most imminent. This danger is not from foes, but from friends; not from determined inaction, but from ill-advised promptitude. Of all men the Commissioners of Sewers are just now most to be dreaded. And this, not from their own error, but simply because work has been portioned out for them; that work they are about to do. It is not their fault, but the fault of the Sanitary Reformers, who commence building the roof of the house, before they have laid the foundation.

The Commissioners of Sewers have appointed a chief engineer, with a salary of 1,500*l.* per annum. They have had sent to them more than 100 plans for draining the Metropolis; the execution of one of these will cost probably

a million of money! It may cost more; but, let it cost what it will, the money will be raised, heavy rates will be made, Government will assist, the engineers will get to work. What will they do? Why, certainly, after an immense outlay, they will succeed in making good sewers for the open parts of the town; they will improve Belgrave-square and Portman-square, Leadenhall-street and Snow-hill. With infinite pains they may even carry their sewers into the worst districts of the town, and effect the sewerage of St. Giles, Bethnal-green, and Horsleydown. They may free the Thames from its loathsome tributaries, and deprive it of the *soubriquet* of the "mammoth-drain." They will, indeed, have then accomplished great things; for to do even so much is a task that will task them to the utmost.

At the end of the time we shall have got rid of our gully-holes; we shall have no cesspools; several subterranean nations of rats will have been extirpated; and that interesting class of men who live in underground London, and breathe an atmosphere composed of equal parts of carbonic acid, nitrogen, and sulphuretted hydrogen, will begin to be reckoned among the very dirty things that were. But shall we have accomplished Sanitary Reform? Shall we have no fever nests?—no cholera-holes?—no storehouses of malignant scarlatina? Will the Registrar-General add ten years to the life of each London artizan; and will the fiery denunciations against our polluted air, which we now read in his admirable Reports, be changed into eloquent dissertations on the superior advantages of a town residence? By no means. Sewered London will be as unhealthy as unsewered London; or, if not altogether so bad, will be as bad for particular districts.

"But how is this?" we hear exclaimed by some enthusiastic engineeer, who has sent in a plan comprising three aqueducts, six tunnels, and an indefinite number of "sumps," and which is to cost the moderate sum of 3,000,000*l*. sterling; "you asked for sewers, you prayed for sewers, you agitated for sewers, you intrigued for sewers, and now, when you are going to have sewers, you pester us more than you did before. After getting a grant of 3,000,000*l*., you want Government to begin sanitary reform afresh. What fresh crotchet is to be now started?"

In answer to this, we would take our indignant remonstrant into any of the back-slums of our back districts,—not the open streets, but the little dark inlets, recesses, and *cul de sacs*, which are arrived at under dim archways, through winding lanes, and narrow fœtid courts. We would say to him, "Observe these tenements; each is one or two stories high, not more; for these fragile walls would never bear a third story; each was built, with the greatest care for the landlord's pocket, without the least thought of the tenants' comfort. In each of these houses, perhaps in each room, live one, two, or even more families—eight, ten, nay, twenty individuals. Observe how every house, and in each house every room, blocks out the air from its neighbour. See these little windows, these low roofs, these narrow dark stairs. Now consider, you possibly may, at enormous expense, carry a really serviceable sewer to each of these houses; each house will cost you as much to drain it as a nobleman's mansion in Grosvenor-square, for you will be obliged to supply water in large quantities, to make your sewers act. And, then, when you have made your sewers, and have expended on each, as much money as the very house is worth, you will not have made the air less fœtid and stifling than it was before; you will not have restored colour to these haggard cheeks, nor driven fever from the plague-stricken dwellings. If you want to know wherefore, take a lesson in the principles of ventilation from that true sanitary reformer, Dr. Arnott, and he will tell you that air is contaminated in many other ways than by cesspools, and that, if you want to purify your atmosphere, you must insure that it shall be able continually to be changed."

We can fancy our sensible Engineer, not yet completely hardened by the three millions he is about to spend, conceding the justice of these remarks,—admitting that the houses are not fit for habitation, that their sewers will be worth more than themselves, but concluding, that if sewers are no remedy for these evils, neither is there any other remedy, unless another great fire should level London to the ground, and a wiser Government than that of old, permit some Sir Christopher Wren to carry out, unimpeded, his great design.

But here is the first point on which we join issue with the Commissioners of Sewers. They are about to drain houses not worth the drainage; to spend money which might be more wisely applied; to commence a great work, which, however necessary, is only part of a vast design, and ought to be kept in due subordination to the principal idea. For we assert, after long consideration of the point,—after long experience of the condition of the poorer districts,—that the only way in which certain parts of London can be purified, is by beginning at the very foundation,—by hurling off these miserable and noxious tenements which now cumber the earth, and by building in their places, houses in which men with immortal souls may not disdain to dwell.

Nor is this by any means so chimerical a scheme as might be supposed. The very system we have hitherto adopted, is one as little economical to the landlord as it is beneficial to the tenant. The landlord, to make the most of his land, crowded his houses together; to build his houses cheap, he built them slight. Consequently, he covered a large tract of ground with small cottages. But if he had built large mansions instead of cottages, houses of six stories instead of houses of two, he would have made as much profit as if he had had three times the ground. Luckily, however, he did not hit upon this expedient; the first great outlay deterred him; had it not been so he would have built houses which would have exaggerated to a gigantic scale the nuisances of the humbler habitations which actually were erected. Had it been left to avaricious landlords to build these tall tenements, we should have been as some of the continental towns are in a slight degree, "cabined, cribbed, confined," within dense barriers of stone and brick.

What the landlord should have done for his own profit in the first instance, and would have done in the worst way, Government should now do for the profit of the working class, and in the most judicious method. For London, and we believe for many of our large towns, there is no alternative. If Sanitary Reform is to be carried out, let us know the extent of the changes which are really necessary. And these changes go to this extent. Vast portions of the worst parts of the town must be absolutely rebuilt; and rebuilt, not in long narrow rows of cottages, but in large mansions, separated by intervals from each other, thoroughly drained and supplied with water from basement story to garret, and inspected regularly by officers appointed by Government, who shall take care that perfect cleanliness is preserved. Some of the model lodging-houses may be taken as a type of these large buildings.

In this way, a population spread over an acre will be lodged in a house, which, built of six instead of two stories, will give to every one more room than he has at present in one-third of the space. Two-thirds of the acre will be left open, in order to insure a thorough circulation of air. These houses will be easily drained, easily kept clean, and easily ventilated. The great obstacle to their formation will be the original cost of the building. The landlords can hardly be expected to undertake this, and may anticipate some assistance from Government. To this they will be so far entitled, because the Government, who have tacitly permitted the present nefarious system of running up small tenements, in which poor people could not refuse to dwell, have been guilty parties to this oppressive and unjust system, and must perform their part in the wiser measures which are to atone for it. And it may be said, if the country is rich enough to build great houses for paupers and criminals from one end of the land to the other, it is surely rich enough to assist its honest and hard-working poor to obtain release from their present pestilential abodes.

One hundred such houses as we propose would blot out St. Giles's, Ratcliffe Highway, Whitechapel, and fifty other harbours of disease from the map of London. It would enable large spaces of ground to be opened which would admit air to the very heart of the City. Gradually as the scheme is worked out, and it cannot be done in a day, the poor quarters of London would disappear. It is by no means impossible, that the dwellings of our very poorest class might vie with the mansions of the Aristocracy in appearance and aspect, or at the least, in salubrity and comfort.

It may be objected to this scheme, that the dwellings we contemplate would be so much superior, not only to the houses of the very poor, but to those of the superior classes of working people, that, after all, we should be building homes for persons who are already well lodged, inasmuch as the better classes would doubtless leave their present dwellings, and crowd into the new houses. This could not be altogether prevented; but, if it occurred to the fullest extent, we should still have emptied for the very poor the abodes of the better classes. The old plague dwellings would

at any rate be away, and our poor would be raised a step in point of accommodation.

The scheme we have now proposed may appear to some extravagant from its extent, and impracticable from the nature of the interests at stake. But if the gradual rebuilding of the poor districts of London appears to any one too gigantic a plan to be carried out, we answer, that it is not one whit too gigantic to cope with the mighty evils it is intended to meet. And it is possible that the difficulties in the way of its execution may appear greater than they really are, and we shall accordingly, in our next Article, examine into the nature of these presumed obstacles, and determine whether they oppose an impracticable barrier to the execution of the plan.

THE HOSPITALS OF PARIS.

The history of the Parisian hospitals in the "olden time" is curious, and full of instruction. Originally they were consecrated almost exclusively to the treatment of the leprous. A writer of the thirteenth century, Mathew Paris, estimated the number of persons who laboured under this dreadful malady, in his time, at 19,000. Of these, France contained no less than 2,000, as we learn from the last will and testament of St. Louis, who left to each of the Lepers' Hospitals the sum of five francs, equivalent to 4*l.* of our present money.

The direction of these Establishments, and of the Hospitals in general, was entrusted to the Clergy and the Bishops. The Church, indeed, was bound to consecrate one-fourth of its fixed revenues to them; but this charge was soon found inconvenient, and was badly paid. The Hospitals were then supported by voluntary subscription, and several were erected independent of the Church.

For a long period, likewise, the administration of the hospitals was entrusted to certain religious orders; but these worthies gradually converted the hospital revenues into sources of personal profit; and Louis XII. was compelled to remove the administration altogether from their hands, and place it in those of the laity, who were at once "solvent and responsible." The hospitals were now directed by a General Council, having under it an Executive Committee; and these continued in authority until the Revolution of February, 1848, overturned this as well as every other authority. At that period the hospitals were handed over to three delegates, by order of the Provisional Government, and these three gentlemen continued in power till the 10th of January, 1849, when the new law on public assistance was promulgated. According to this law, the hospitals are placed under the authority of the Home Minister and the Prefect of the Seine, and their direction confided to an Inspector-in-Chief, with a Superintending Committee appointed by Government. This latter Committee is now composed of twenty members, viz., the Prefect of the Seine, President; Prefect of Police; two Members of the Corporation, two Mayors, two Municipal Officers, a Member of the Council of State, of the Supreme Court of Appeal, a Physician and Surgeon of one of the Hospitals, a Professor of the Faculty of Medicine, a Member of the Chamber of Commerce, and six other individuals.

From the above it would appear, that the Hospitals did not assume any degree of importance as public establishments until they were completely removed from the hands of the clergy. This occurred about the middle of the seventeenth century, when nearly all the old hospitals were taken down and replaced by buildings better calculated to fulfil their objects. One of the first to disappear was the hospital "des Petites Maisons," founded in 1497, to receive patients attacked by the Neapolitan or venereal disease. The present Hospital des Menages, Rue de la Chaise, is built on the site of this old establishment. Soon afterwards followed the Hospital de Jesus, built in 1653; the Convalescents of Charity, founded in 1142; the Hospital of St. Gervais, founded in 1171; many Houses of Refuge; the Hospital des Enfans Rouges, founded by Marguerite de Valois, Queen of Navarre; the Hospital of St. Catharine, Rue St. Denis; the Enfans Trouvés of the Faubourg St. Antoine, various Hospitals for orphan children and pilgrims, and a great number of other establishments of a similar kind.

Many of these still existed at the middle of the last century, and the greater part were only suppressed by the great Revolution of 1793. At that period the city of Paris possessed no less than forty-eight Hospitals, of which twenty-two were exclusively devoted to patients; twenty to persons not labouring under disease; and six to both classes. 20,000 persons were daily treated or fed in these immense establishments, without counting the foundlings, who amounted to 15,000. The administration was necessarily imperfect, and the Government was about to realise the reforms proposed, when the great Revolution broke out, and the property of the hospitals, then amounting to about 300,000*l.* per annum, was put up to public auction by the Republican authorities. The confusion which followed these unfortunate times was long unfavourable to the Hospitals; but they have at length recovered, and attained a degree of perfection which now renders them worthy of the admiration of Europe.

The actual number of civil Hospitals and Infirmaries in Paris is twenty-five. They may be distinguished into general and special. The general Hospitals are nine, and contain as many as 3715 beds, viz.:—

Hôtel Dieu	810	beds
La Pitie	620	"
La Charite	429	"
Beaujon	492	"
Neckar	320	"
Bon Secours	300	"
St. Marguerite	300	"
St. Antoine	320	"
Cochin	125	"

The special Hospitals are six, and contain 2819 beds, viz.:—

St. Louis (skin)	825	beds
Hospital du Midi (lues men)	300	"
Hospital de l'Ourcine (lues females)	300	"
Enfans Malades	600	"
Maison d'Accouchement	514	"
Hospital des Cliniques	120	"

To these we must add the National Sanatorium, Faubourg St. Denis, which is capable of receiving 150 patients, and belongs to the State. In ordinary times the patients pay so much a week; but in cases of emergency, as after the insurrection of June, and during the cholera, this establishment is susceptible of being converted into an excellent Hospital.

The "hospices," or Infirmaries, are asylums open to all those whose poverty, old age, infancy, madness, or incurable infirmities disable from obtaining a livelihood. These, again, may be distinguished into Hospices, properly so called, and Houses of Refuge. Patients are received gratuitously into the former. Admission to the latter is obtained on payment of a small annual sum or donation.

The Hospices are eight in number:—

La Vieillesse, (men; formerly called Bicêtre), 3080 beds; of which 830 are devoted to the insane, and 2250 to the aged or infirm.

La Vieillesse, (women; Salpêtrière,) 4901 beds; 1440 for the insane, and 3461 for the aged.

Incurables (men)	510	beds
Incurables (women)	604	"
Foundlings and Orphans	600	"

In addition to which nearly 23,000 foundlings are sent out to nurse in the country.

Hospice Devillas, 35 beds, for the indigent of both sexes above 70 years of age. There are, also, two other establishments of the latter kind under the Commission, viz., the Hospice St. Michel, founded, in 1830, by M. Boulard, and containing 12 beds; and that of La Reconnoissance, founded by M. Brezin in 1833, and receiving 300 old workmen.

The "Houses of Refuge" are the Hospice des Menages, 742 beds; exclusively confined to widowed persons or householders, who pay a fixed sum annually.

The Hospice de la Rochefoucauld, 213 beds, for old people who can pay 20*l.* a year; and, finally,

St. Perine, with 182 beds, for those who can pay 21*l.* annually.

In addition to these establishments for the treatment of the sick, or the refuge of the infirm, there are several accessory ones, through means of which considerable economy is obtained in the working of so vast a system.

The "General Bakery," for example, founded in 1801, manufactures all the bread consumed in the Hospitals and Infirmaries.

The "General Wine Cellars," opened in 1816, receive all the wine necessary for one year's consumption. Besides which, these two establishments contain immense provisions of vegetables, oil, &c., in fact, of everything which is consumed in any great quantity. The saving of expense is thus enormous.

The "Central Pharmacy," opened in 1796, receives and prepares all the medicines required by the Hospitals and Infirmaries. It likewise supplies, on contract, the Dispensaries, Prisons, and a few other public establishments.

Lastly, to complete this brief sketch of the Parisian Hospitals in their *ensemble*, we must notice the "Bureau Central," composed of sixteen physicians and four surgeons, whose duty it is to examine all cases—except those of urgency—previous to their admission into Hospital. The members of the Bureau Central are all chosen by concours, and from amongst them the Government is bound to select the Hospital Physicians and Surgeons, according as vacancies may occur.

The "externes" and "internes" are likewise chosen by public examination, and correspond exactly to the "dressers" in English Hospitals. The candidate for the "externat" must be 18 years of age, and have taken out one inscription, at least, to the Faculty of Medicine. The "internes" are elected from amongst the *externes* of one year's standing. It is altogether an abuse of words to translate either of those terms by "House-Surgeon," or "House-Physician."

When we reflect, that 90,000 patients are annually received into the hospitals of Paris—that 14,000 old and infirm persons are supported in its infirmaries—that 5,000 foundlings are taken in, and 23,000 sent out to nurse—and, finally, that domiciliary assistance is afforded by the Administration to 30,000 indigent families—we may form some idea of the immense efforts made to relieve such an amount of human suffering. Yet the revenues are not very great. They are chiefly composed of 12,000*l*, a year, derived from the excise duties of the city; 240,000*l*. a year from capital, the tax on theatres, on pawnbroking offices, &c.; and about 12,000*l*., the capital of donations or legacies. Yet these sums, considerable though they appear, are far from meeting the wants of the population.

In a succeeding Article, we propose to give a brief notice of the different Hospitals in particular.

THE OPERATIVE SURGERY OF JOHANN FRIEDRICH DIEFFENBACH.

Edited by ALEXANDER URE, Esq.,

Fellow of the College of Surgeons of England, and Surgeon to the Westminster General Dispensary, &c.

(Continued from page 384.)

CHAPTER X.

OF THE TORSION OF ARTERIES.

(*Torsio Arteriarum.*)

Torsion implies the twisting of an artery, so that a mechanical and afterwards an organic closure of the vessel is effected.

The Profession is mainly indebted to Mons. Amussat for the introduction of this method of arresting hæmorrhage.

Torsion is recommended in the instance of bleeding from vessels of the second class, especially when the wound is to be directly closed, so as to avoid ligatures. Here it possesses the advantages of being done quickly and without aid, important considerations when the surgeon is alone. It is very useful to obviate bleeding into cavities. After operations for strangulated and adherent ruptures, which require to be relieved with the knife, I have twisted divided arteries and veins, and then replaced the intestines in the abdomen without any internal hæmorrhage ensuing. In other cases again, where numerous arteries of the omentum were pouring forth blood, I have applied fine thread ligatures, cut these off close to the knots, and never known any mischief result.

On the other hand, torsion is less eligible for large, gaping wounds, with loss of substance, because as these are generally filled with soft lint, the ligature of the arteries cannot be held as any mechanical irritation. The application of torsion to arteries of large calibre is hazardous, because insecure; secondary hæmorrhage, violent inflammation, and puriform disruption of the vessel with, gangrene of its tunics, may possibly supervene. To insure success even with the ligature, a healthy condition of the vessel is indispensable, and still more so in reference to torsion, where brittleness, degeneration, unnatural rigidity, but, above all, ossification of the coats, render all attempts of the kind difficult and nugatory.

The action of torsion is that of pinching, lacerating, and compressing the internal coats, through the medium of the firm external cellular envelope.

It speedily determines occlusion of the arterial canal, and, ere long, by the twisting of the sort of knot, a shortening of the extremity of the artery, which, in virtue of its natural elasticity and retractile power, is drawn into the surrounding soft parts, so as to lie rather within than upon the surface of the wound. In other respects, with abstraction of inflammation in and around the artery, the sequel and phenomena of torsion are analogous to those of ligation. We find the formation of a coagulum in the vessel, which extends to the first collateral branch, further exudation upon the internal surface, re absorption of the clot, and transformation of the inferior extremity of the artery into a cord.

Torsion may be executed by means of common forceps with broad nibs; or else with the so called torsion forceps of Weiss, furnished with a bolt sliding into a loop, which serves to prevent it slipping off the vessel.

1. OF THE TORSION OF BLEEDING ARTERIES.

The extremity of the divided artery is to be taken hold of as if applying a ligature, then drawn a few lines forward, next insulated from the adjunct parts, the incumbent cellular texture being stripped away by the aid of common dissecting forceps. These, held between the index finger and thumb of the left hand, serve to fix the artery. The torsion is now performed leisurely and continuously until the portion grasped by the torsion forceps is completely twisted off. Small arteries require three or four rotations upon their axis; larger, from eight to ten. Should the artery be untimely lacerated, and the bleeding return, it must be drawn out a little further, and the torsion carefully repeated. No special after-treatment is called for, as the wound usually heals by applying sutures and adhesive stripes.

2. OF THE TORSION OF ARTERIAL TRUNKS.

The observation that an artery, when transfixed, crushed, or made to inflame, by the intervention of a temporary ligature, becomes obliterated at the very spot, led Thierry to conceive that the same thing might be effected through methodical twisting of the vessel by means of a hook. Lieber previously found that when the carotid was thus treated, inflammation, extending to the heart or brain, was readily induced. During such manipulations it is scarcely possible to avoid injuring or including some nervous filament; the artery, moreover, is prone to burst open, its walls, are liable to mortify from the violence done, to rupture, and, of course, left without any prospect of a coagulum being formed.

A second mode of torsion recommended by Thierry consists in insulating the aneurismal artery above the seat of the disease, as in applying a ligature, then cutting it across and twisting it at each end. This resembles the plan of applying two ligatures and dividing the artery in the interspace, and is still more reprehensible.

The following are supplementary methods:—

1. The stripping of the internal and middle coats of the artery—(*torsion avec refoulement*).

This is more insecure than ordinary torsion in the instance of bleeding vessels, and very perilous in that of voluminous undivided arteries, because, when the internal and middle coats are severed from the filamentous, the latter is readily ruptured, and no proper coagulum can ensue. Amussat, the inventor of this method, seizes the artery crosswise with forceps, then pinches it with another forceps, till the internal tunics give way, and gives it two or three turns. By this manœuvre the internal and middle coats are shrivelled up and inverted inwardly, so as to form a kind of *cul-de sac*, or valve, which arrests the column of blood. But that is still more efficiently restrained by the hood or pivot formed by the cellular sheath.

2. The crushing of the internal tunics with broad nibbed forceps.

3. The twofold compression of Malgaigne and Le Roy d'Etiolles, with the simultaneous agency of cold, or of galvanism, to promote the coagulation of the blood; a plan of doubtful efficacy.

4. Transfixing the artery with a needle to be left, *in situ* as proposed by Velpeau, or with a thread, has not been sanctioned by the Profession, and is not likely to replace the ligature.

5. The noosing of the vessel itself has been gravely advocated by Stilling. Through a small longitudinal aperture made in the artery near its margin the end is drawn, by which the former is closed, and the formation of a coagulum, inflammation, and, adhesion induced. The operation, however interesting as a physiological experiment, is inadmissible in surgical practice. [While torsion may be occasionally resorted to as a means of suppressing hæmorrhage from veins and from arteries of the second class, it is never likely to supersede the use of the ligature.—A. U.]

CHAPTER XI.

THE OPERATION FOR ANEURISM.

Operatio pro Aneurismate.

The operation for aneurism consists in the tying of the morbidly dilated artery, in order to divert the current of blood into the collateral vessels, so as to determine a closure of the artery and a dwindling of the aneurismal sac. There are different methods of operating.

1. Tying the artery immediately above and immediately below the sac, and then laying that open.

2. Tying the vessel superiorly at some distance from the pulsating tumour, namely, between it and the heart.

3. Tying below the sac, consequently on the side remote from the heart. After the discoverer, the first method is called that of Antyllus, the second that of Hunter, the third that of Brasdor.

The operation may be resorted to when the aneurismal tumour is incurable by compression, and, instead of retroceding, is advancing. It is contra-indicated on the other hand by the co existence of kindred tumours in other arteries, more especially where, besides the external, there is also an internal one; when the aneurism occurs in a person stricken in years, or shattered in constitution; when it has outrun its various stages, ceased to pulsate, and a natural cure may be anticipated; when the member in which it is situate is wasted, œdematous, and benumbed; when the main arterial trunk and the collateral branches are ossified, even although the adjunct textures be apparently unchanged; finally, when other important parts are diseased, there being carious bone for example.

The method of Antyllus is eligible only in the instance of false aneurism, which has originated through the wound of an artery, as that at the bend of the arm after bloodletting, and more particularly where the swelling is large.

The practice of tying the artery high up for false aneurism very seldom succeeds. In general, the pulsation in the tumour remains after the application of the ligature just as before, because the collateral circulation is constantly conveying a large amount of blood by the numerous anastomoses. After several operations of the kind, I have not witnessed a single case in which false aneurism was cured by the proximate or remote ligation, and after fruitless trials have always been obliged to return to the method of Antyllus.

By first laying open, then emptying the sac, and tying the vessel immediately above and immediately below the orifice, can the disease be alone cured. The mere tying above the orifice will in no wise diminish the bleeding from the wound in the artery, nor will the latter be suppressed until the inferior ligature is also applied. The only ground which can authorise the surgeon to deviate from the above course, and to tie the artery at some distance either higher or lower, is the fact of its being thickened or disorganized by inflammation. The method of Antyllus again ought uniformly to be rejected in the instance of true aneurism, whether recent or of long standing,—whether the sac be sound, or ready to give way from inflammation or gangrene. Precisely here, where this method is vaunted, is it least of all admissible. For, where an aneurism is inflamed, and tending to gangrenous disruption, not only the artery, but the whole of the surrounding parts, are diseased. The ligature cuts through

the vessel without causing its obliteration, and a dangerous secondary hæmorrhage is the result, the more alarming, because the patient must have necessarily lost a deal of blood during the operation. It ought to be mentioned, moreover, that an exhausting suppuration is almost always established at the situation of the opened and evacuated aneurism, and the limb, even when this has been surmounted, becomes frequently useless. On account of these serious consequences, amputation was wont to be performed in preference to the operation of Antyllus. The said method is, besides, perilous in true aneurism, because the latter is commonly deeply seated, and confined, for the most part, to the great vascular trunks. The nerves and veins accompanying the arteries are often blended with the thickened walls of the sac, and prone to be injured during the operation. Equally important is the proximity of a joint, as, for example, at the bend of the leg. Frequently the inflammation extends, after the operation, over the knee joint; meanwhile purulent deposits form in different directions among the muscles. Thus, in the event of a cure, the limb is anchylosed, or, at all events, fixed at an angle, with a chance of regaining partial mobility at a subsequent period.

It is, therefore, manifest, that the method of Antyllus is adapted to false aneurism exclusively.

The advantages which Hunter's method offers, in reference to true aneurism, are very great. Far from the seat of the disease and of danger, is the artery laid bare at a healthy spot, by a simple incision, tied with a fine thread, and the wound healed by the first intention. The aneurismal tumour, deprived of its supply of blood, ceases to pulsate,—collapses. The process of absorption furthers the removal of the sanguineous deposits, and of the thickened walls of the sac, and eventually reduces even very large aneurisms to inconsiderable indolent swellings.

It has been urged against the Hunterian method, by the partisans of that of Antyllus, that, in consequence of the subsequent re-filling of the sac, there is imminent danger of its bursting. This contingency has been, however, seldom observed.

The surgical treatment of aneurism has been materially aided by the new light shed on physiology by the introduction of the subcutaneous method, and which has tended to demonstrate the great superiority of the Hunterian operation over every other.

REVIEWS

The Cyclopædia of Anatomy and Physiology. Edited by Dr. R. B Todd. Nos. 30 to 36 London Longman and Co.

It has often been observed to us, that something more than a simple notice of the excellent Work mentioned above, would be a boon to those who wish to know the nature of the contents of a book before they purchase it, and especially to others who take an interest in the science of their Profession. We propose, then, to review the last six Numbers, not in their serial order, for we shall classify the articles of which they are composed under certain heads, and present our readers with separate papers upon General and Special Anatomy, Physiology, Pathology, Comparative Anatomy, and Chemistry. The contributors to the last six Numbers are John and Robert Adams, J. E. Bowman, Dr. Brinton, Dr. W. B. Carpenter, Dr. P. M. Duncan, Dr. Guy, Dr. Johnson, T. Rymer Jones, Dr. Lankester, Professor Kolliker, Dr. M'Dowel, Joseph Maclise, Simon Pittard, G. O. Rees, Wm. Trew, Professor Vrolik, Dr. Walshe, Dr. John Reid, N. Ward, Esq., and the learned Editor. We find, under the head of General Anatomy, articles by Joseph Maclise on "Skeleton;", by Dr. Brinton, of King's College, on "Serous and Synovial Membranes;" and by Mr. Pittard, on "Sesamoid Bones."

The first on the list, the article "Skeleton," by Maclise, is a very clever production; it is not as a specimen of close reasoning alone, that it is worthy of the work into whose composition it enters, for it gives evidences of a thorough knowledge of philosophical anatomy, and contains numerous well-executed sketches. Our Author's style is, however, anything but flowing, being in some places amusingly complex, often absurdly obscure, and not infrequently his sentences are utterly devoid of meaning. Oken carried oddity of nomenclature and expression, to its supremest degree; but we have to thank him for the first hint of the existence of cranial vertebræ. To Owen is the merit due of having done more than any other towards giving us a taste for the study of Anatomy as a science, for it is practised in our dissecting rooms as an art, whose principles are not understood.

Carus, Geoffroy, St Hilaire, Meckel, Nitsch, Vicq D'Azyr, and others, have, by their eccentric wording, rendered transcendental anatomy, any thing but a pleasing study; our own language can convey the most abstract ideas, without the coining of words which strike harshly upon the ears of those who have a moderate classical knowledge, and which a Greek would barely recognise. Leibnitz, Bacon, Newton, Dugald Stewart, and Pascal, each in the most simple style of their languages, conveyed ideas which have immortalized them. Why cannot our philosophic anatomists do the same? Why do they strangle their good ideas in their birth, with words suited for puffing hairdressers alone? To return to our more immediate subject, the essay before us consists of 46 propositions, each of which is indispensable to the whole, in old Euclid's style. The skeleton is treated throughout as an abstract general title, having to do with the osseous fabrics of the four higher classes of animals, and our Author's object is, "to strive to elicit the law which creates them in the character of a unity in variety, a condition of form by which the many species gather themselves together naturally into a circle, and point to some unknown oneness of character which enchains them the one to the other."

"My argument shall set out from a first proposition, through a successional enchainment of propositions, and, in the manner of all propositions taken collectively, I shall body forth an interpretation hitherto unknown in anatomical science."

Also,—

"To demonstrate the figure of unity, and give interpretation to the figures of variety which are sprung of it To this end I shall prove—1. That all the osseous skeletal forms are quantitatively unequal things. 2. That they are the unequal quantities of a greater or archetypal form,—a unity which has undergone such an infinitely graduated metamorphosis of its parts, as to yield these unequal skeletal forms. 3. That the law of formation is one of degradation of an archetypal uniform original. 4. That these unequal skeletal forms constitute the species or varieties of the unity of the archetype."

And it follows from this,—

"That when the series of archetypal quantities suffers metamorphosis at certain lines, which the creative hand of Nature draws through it, the animal design or species is struck out accordingly."

The meaning of the terms—Archetype, Homologue, Analogue, Quantity, Proportional, and Series, are, with the exception of the first, so constantly in general use as not to require any definition. With regard to the term Archetype, it is "some integer or full skeletal figure, which might be seen as containing, in its own quantitative character, the sum of all known varieties or species." A dorsal vertebra, with both ribs and piece of sternum attached, is the vertebral archetype, as we shall see anon.

Propositions 1 to 4 relate to vertebræ in general. There is a general likeness in all vertebræ; and when we place a cervical, dorsal, (with the ribs and sternal piece attached, for they have no business to be removed,) lumbar, sacral, and a caudal vertebra before us, we notice, that they are each distinguished by the presence or absence of certain prominences or quantities. "A coccygeal vertebra is only different from a lumbar or cervical vertebra by quantity; and a skeleton of a frog is different to that of a whale, by the condition of variable quantity also."

Propositions 4 to 11 refer to the classes of vertebræ especially as regards "ribs." It is first of all shown, that, by removing the costal appendages of a dorsal vertebra, we render it an artificial figure; they cannot be separated except by direct removal; they always remain in the mind's eye; for we find that the anterior half of the transverse process of a cervical vertebra is the true homologue of a thoracic rib, whilst the posterior half is that of the transverse process of a dorsal vertebra. Do not we find the anterior half of the cervical transverse process occasionally prolonged into a rib in man? —and are not the two halves of the transverse process the products of two ossific centres? All cervical vertebræ, then, develope costal appendages. It is sufficiently obvious, that what is usually termed the transverse process in the lumbar vertebræ, is not the homologue of the transverse process of a dorsal. The true homologue is the tubercle in relation with the upper articulating processes. The lumbar (so called) transverse process, is the ill-developed costal appendage, and corresponds to that of a dorsal vertebra. Both Cruveilhier and Meckel notice, that the lumbar transverse process sometimes remains articularly separate; it, moreover is, as in the case before us, occasionally prolonged into a perfect costal form. In each lateral mass of a sacral vertebra, we notice an anterior and a posterior nucleus; the former is the homologue of the so-called transverse process of a lumbar vertebra, and, of course, of the thoracic rib, whilst the latter corresponds to the lumbar tubercle and the transverse process of the dorsal vertebra. The coccygeal vertebræ are the debris, or metamorphosed remains of true and complete vertebræ; the round mass, or centrum, "holds series with the centra of all other vertebræ."

Now the first seven dorsal vertebræ, with their attached ribs and sternal pieces, have an absolute linear uniformity; there is no specific difference between them; and Maclise terms them whole, or plus, or complete vertebral quantities; they are his archetypes. Nature produces specific differences from out of this linear series of thoracic archetypes. Cervical vertebræ are minus quantities, if the archetypal vertebral form is plus; they are wanting in rib development, so also are the lumbar and sacro coccygeal vertebræ, and those dorsal vertebræ which produce asternal ribs. Maclise says, "I conclude that such species results not by the positing of new and unknown quantity, but by the annihilation or degradation of already known and posited quantity." The dorsal vertebra, with its ribs and sternal piece, —the costo-vertebral archetype,—contains within itself the elements of all other vertebræ.

In a foot note, our Author notices how and why he differs in his views of a typical vertebra, from Owen, Carus, and others:—

"I do not, for example, think it necessary to see, in the typical form, so many elements and parts as those which Owen names, in order to render it inclusive or archetypal of all varieties of vertebræ."

The German, who has to wade to philosophical anatomy through Carus, and who meets with such barbaric terms as Bogenstücke des Rüchenwirbels, Ober-sternal thiel, des Urwirbelbogens, and Seitcher Tertiar-wirbel, will be very grateful for a little simplicity. Moreover, the

opinion that Carus, De Blainville, and Meckel have advanced, that the sternum is a series of vertebræ, is no longer retainable, if we coincide with Maclise, and we must do so if we admit his 16th Proposition,—

"The mammalian spinal axis consists of a series of segmental quantities, whose only variety or specific distinction depends upon proportioning from whole thoracic quantities."

Fig. 455, shows in dotted outline at the neck and loins, the costo-sternal quantities, which, if present, would render these regions equal to, and uniform with, the thorax.

After showing, in Proposition 30, that anomaly is a link in the chain of form,—for cervical and lumbar ribs, are anomalous to the ignorant only, whilst they assist the philosophic anatomist,—we are told, as a necessary consequence upon the previous propositions, that—

"All the spinal segments of all classes and species of vertebrated animals, are only as the variable proportionals of sterno-costo, vertebral archetypes."

And then we come to the very important 32nd proposition, which is the point at which the Author and Owen seriously begin to disagree :—

"The hyoid apparatus occurs opposite to the cervical spinal region, where we know costal quantity to be lost. The hyoid apparatus refers to the cervical vertebræ, and consists of their ribs metamorphosed."

"Owen considers the first circle of the fish's throat apparatus, as the only part of it which is homologous to that of other animals, and all the succeeding arches, three or more in number, and all similar to the first, however, as appertaining to the splanchno skeleton, or that category of bones, to which the heart bone of ruminants, and the hard jaw-like pieces supporting the teeth of the stomach of the lobster, belong."

And again at pp. 114-15—

"The third inverted arch of the skull is the hyoidean. I regard it as the costal or hæmal arch of the parietal segment or vertebra of the skull."

Our space will not allow us to follow the Author of this Article further, but from the analysis of its contents we have given above, our readers will have no hesitation in according it a high place among the writings on Transcendental Anatomy.

REPORTS OF SOCIETIES.

WESTMINSTER MEDICAL SOCIETY.
Dec. 22, 1849.

F. Hird, Esq., President, in the Chair.

INTESTINAL ULCERATION IN TROPICAL DYSENTERY AND DIARRHŒA — GLANDULO FIBROUS TUMOUR—GELATINOUS POLYPUS OF THE EAR—TUMOURS IN THE FEMALE URETHRA—EPILEPSY AND PUERPERAL CONVULSIONS.

Dr. James Bird exhibited several coloured drawings, illustrating forms of ulcers, as they occur in varieties of tropical dysentery and diarrhœa. Plates *fourth* and *fifth* represented dysenteric ulceration within the tropics, originating in simple inflammatory diffused action of the follicles, and specific chronic inflammation of the same, following tubercular deposit in the sub-mucous areolar tissue; where the transformations of the mucous intestinal coat closely resemble the progress of tubercles in the lungs. These two forms of ulceration give rise to two distinct forms of dysentery, which Dr. Bird characterised by the names of the phlogistic and cachectic forms of the disease, and which require very different systems of treatment; general and local bloodletting being of great utility in the former, though very little required for the latter, in which sub-nitrate of bismuth, or sulphate of copper, with opium, frequent emollient opiated enemata, blistering of the abdomen, strict limitation to milk and farinaceous diet, with change of air and other adjuvants are specially indicated. The first case, from which plate *fifth* was taken, was one of acute inflammation preceding a state of chronic irritation, and producing severe dysentery.

Case 1st.—Gunner Larkins, aged 28, resident three years in India, was admitted into the Artillery Hospital at Bombay, on the 4th of November, 1825. He complained of having frequent ineffectual calls to stool, and of being able to evacuate nothing from his bowels but small quantities of bloody mucus; had severe tenesmus, accompanied by general tenderness of the abdomen, nauseous, sour taste, white tongue, much thirst, heat of skin, and fulness of pulse. Was bled on the first and second day of his admission, used the warm bath, had calomel with large doses of opium, followed by castor oil, with leeches and a blister to the abdomen. Died on the fourth day after his admission, in a convulsive fit, during the administration of an anodyne enema.

Inspection.—The cardiac extremity of the stomach internally presented a bright red vascularity, and the villous coat throughout was covered by thick adhesive mucus. The contents of the stomach consisted of green bilious fluid and mucus; the small intestines were natural in appearance, but distended by flatus; the valve of the cœcum was thickened and contracted. The large intestines were thickened; the mucous coat ulcerated, and such parts of it as remained entire were of a slate colour and inflamed, but without any appearance of mortification. The liver was of a reddish purple colour, diversified on its surface by white spots. When cut into, similar spots were observable, and the inter-lobular tissue between each was of a bright red. The spleen was natural. The lungs were not fully collapsed, and there was a great degree of congestion in the vessels of the pia mater. In this case the interlobular tissue of the liver was more vascular than its glandular secreting substance, and this diseased state may have been of cotemporary origin with the chronic irritation of the sub-mucous tissue of the intestines which produced the hypertrophy.

In *cachectic dysentery* the process of ulceration is connected with a more atonic state of inflammation than is observable in cases of the phlogistic kind. The aggregated or solitary follicles of the intestines are enlarged, previous to the inflammation of the mucous membrane which terminates in their ulceration, and sometimes tubercular matter deposited in the sub-mucous tissue, produces inflammation and abscesses which burst through it. In both instances the ulcers are of an oval or circular form, as in plate fourth; and cream-coloured tubercles, or small distinct abscesses in the liver, complicate this variety of dysentery. The disease frequently proves very intractable, and is less under the influence of medicine, than the purely phlogistic and hepatic varieties. Frequently one set of ulcerated follicles heal up, while others become inflamed, and renew the symptoms of dysentery, which have for a time disappeared. The following case will illustrate this variety of disease.

Case 2nd. Gunner George Geddes, aged 24, and just arrived from England, was admitted into the Artillery Hospital at Matoonga, on the 20th November, 1825. He complained of tenderness in the site of the colon; passed nothing but blood and mucus from his bowels; was suffering severely from thirst, griping, and tenesmus; had alternate chills and hot flushes, while his pulse usually numbered 86. He was bled, blistered, used mercurial inunctions, with a warm bath, and took calomel with opium, till the gums became tender. The constitutional effect of mercury appeared to increase the irritability of the bowels, and the frequency of the alvine evacuations. He died on the 26th following, being the twentieth day from the time when he observed the first symptoms.

Inspection. The body was of natural appearance, but of slender make. The cœcum, which was internally much inflamed and ulcerated, had lost its natural cohesion. In the transverse arch of the colon numerous small round ulcers were found; the sigmoid flexure was similarly ulcerated, but in a less degree. The ileum, where it joins the cœcum, had a rough warty appearance, from enlargement of its follicles. The glands of the mesentery were much enlarged, and the omentum, which was drawn up from the left side towards the cœcum, adhered to this intestine and the abdominal parietes. The villous coat of the stomach, which had lost its natural cohesion, was easily torn by the nail, and exhibited numerous purple spots, produced by effusion into the sub-mucous tissue. The liver, anteriorly, was of a reddish brown colour, and posteriorly, for several inches from its edge, was deep black. The lungs were fully collapsed, but contained several white tubercles of a soft texture. In the following case, the ulcerations in the solitary glands of the large intestines had a tubercular character, and were associated with great tubercular deposits in the secreting substance of the liver, the interlobular tissue of which was of a deep purple colour, communicating to the whole the usual appearance of the *nutmeg-liver*, as represented in Plate 2.

Case 3.—Gunner Thomas Hoult, aged 25, who had been three years in India, was admitted into the Artillery Hospital, at Matoonga, on the 10th of December, 1825. He complained of dull pain at the umbilical region, increased by pressure; had frequent ineffectual calls to stool, and passed nothing but bloody mucus. The thirst, griping, and tenesmus which accompanied these symptoms were great; his pulse numbered 90 at admission, and increased, after bleeding, to 110; and febrile heat of the skin, with pain in his limbs, was occasionally present. He was not benefited by any remedy, and died on the fifth day after his admission, and the 13th from the time he observed the first symptoms.

Inspection.—The large intestines were thickened internally, and much ulcerated. The ulcerations, which were of a circular form, varied from a line to half an inch in diameter. The villous coat between each was of a light crimson colour. The glands of the mesentery were enlarged. Numerous grey tubercles, varying in size from a pea to a pin's head, studded the substance of the liver, and were surrounded by deep purple discoloration, as represented in plate 2. The villous coat of the stomach was of a light crimson, and was softened. Ulcers of the jejunum are of comparatively rare occurrence, so much so, that Andral places them, in respect of frequency, but one degree higher than ulceration of the duodenum. The following is an interesting case of this kind, where the ulceration was of an oval form, and appeared to have commenced in the follicles of Lieberkuhn.

Case 4.—Edward Clarke, gunner, aged 24, admitted into the Artillery Hospital at Bombay on the 4th December, 1825, complaining of pain and tenderness at the umbilicus, accompanied by purging of frequent, loose yellow stools, mixed with flakes of mucus. Had a hoarse, sounding, troublesome cough, and expectorated a considerable quantity of tough yellow mucus; body much emaciated; feet anasarcous; little or no appetite; tongue clean; pulse small and irritable. Had been sent to Bombay from one of the military out-stations, where he had been under medical treatment for upwards of three months. Was the subject of frequent attacks of dysentery, since his arrival in India in 1821, and suffered much from derangement of his general health. The medical officer who attended him in the commencement of his present attack, reported that the abdomen was hard and tumid, and that the thickened state of the colon could be traced throughout its course. An alterative course of blue pill, with ipecacuanha, and gentle doses of rhubarb, were had recourse to without any good effect, and the only medicine which diminished the frequency of the motions was ipecacuanha, in ten grain doses, united with thirty-five to forty drops of laudanum. He died on the 15th of December, eleven days after his admission.

Inspection two hours after death.—The body was much emaciated.—*Abdomen.*—The villous coat of the stomach, which was thrown into rugæ, was of a light crimson colour, and somewhat softened. The duodenum and jejunum at the upper part were hypertrophied; and the mucous coat of the latter intestine was occupied by several small ulcers, which were in various states of advancement, having their origin, as it appeared, in the follicles of Lieberkuhn, accompanied by general diffused vascularity of the mucous coat. In the ileum, the patches of Peyer's follicles were generally in a state of ulceration. The cœcal valve was much contracted, and in a state of dark red vascularity; as was also the mucous coat of the colon. The mesenteric glands were enlarged. The spleen was softened. The liver, which weighed four lbs. two oz. was of a green bilious tinge throughout its texture, and exhibited on its surface a mottled appearance of red and white circles, produced by hypertrophy of the white secreting substance, and chronic red vascularity of the interlobular tissue. The right lobe contained a small hydatid. *Chest.*—The superior lobe of the right lung adhered to the costal pleura, and contained several grey miliary tubercles, some of which had suppurated. The left lung was also adherent to the costal pleura. The heart was small and atrophied.

Mr. Travers, jun., exhibited a glandular tumour, which he said presented some peculiar appearances under the microscope. It was about the size of a pigeon's egg. He had removed it with comparative facility from the side of the face, it having but one deep connexion, near the bony edge of the meatus auditorious. His patient was a lady, twenty-six years of age. It presented the aspect of a glandular

tumor, and that view of its character was confirmed by Quekett. It was, however, an interesting specimen, inasmuch as it was a rare instance of the true glandular structure changing into the fibrous Under the microscope it showed a prolongation of fibres in different directions, extending from the central nuclei or cells, meeting and decussating. Its position proved it to have been originally a lymphatic gland. (Drawings were exhibited, illustrating the process of change in the tumour.)

Mr. Harvey exhibited a gelatinous polypus extracted from the membrana tympani. The patient was a lad sixteen years of age. He had had a discharge from the meatus, of an offensive odour, for four or five years previously. This ceased on the removal of the polypus, and the boy's hearing was restored. The morbid growth did not recur.

Mr. Hillman, jun, narrated the case of a married lady, twenty-six years of age, the mother of two children, who for many months had suffered from severe pain while passing water, while walking, and at the catamenial periods, as well as during intercourse. Pain was occasionally experienced in the inside of the thighs, and in the rectum. She had been treated for gravel for some time, but without advantage. On examination there was found a thick white discharge from the vagina, and several small growths from the orifice of the urethra and the commencing part of that canal. Pain was complained of when pressure was made with the finger in the vagina against the pubes. The passage of the catheter was painful, and caused slight hæmorrhage. Chloroform was exhibited, and the granular eminences were destroyed by potassa fusa; the urethral growths being removed with their base, and a portion of the surrounding sound textures. The urethra having been dilated, another growth, about one-third nearer the bladder, was extracted. The little finger was then passed in along the canal, which was found to be perfectly clear. In the evening the patient suffered much pain from the passage of the urine over the denuded surface; hæmorrhage, to the amount of a pint, occurred the next day. A purulent discharge followed on the fourth or fifth day, when the bladder could retain about three quarters of a pint of urine. The discharge increased in quantity for a few days; by the eighth the sloughs separated, and the patient gradually got better. In two months afterwards was quite well. Mr. Hillman, jun., remarked, that he brought this case forward to show the utter inutility, in some instances, at least, of endeavours to treat disease, without previously instituting a proper examination. Here was a patient who had been under professional care for some time, and had been treated for gravel, her complaint all the while depending on abnormal growths in the urethra. There was another point worthy of notice, and that was, the occurrence of secondary hæmorrhage the next day, although very little blood indeed had been lost when the operation was performed. This, he believed, was a usual occurrence in such cases.

Dr. Tyler Smith then read a paper

ON SOME OF THE RELATIONS AND DIFFERENCES BETWEEN EPILEPSY AND PUERPERAL CONVULSION.

Dr. Tyler Smith referred to the prevalent belief that some connexion exists between epilepsy and the convulsions of the puerperal state. The two diseases are so far alike, that any one, reasoning *à priori*, would be apt to suppose that the existence of epilepsy before gestation would predispose to convulsions during labour. The author, however, pointed out, that upon a closer examination, certain differences of a marked character would be found. Epilepsy is generally a chronic, puerperal convulsion an acute affection. Epilepsy generally begins, in each attack, by the characteristic aura, whereas there is nothing like an aura in puerperal convulsions. The asphyxia is far deeper in the puerperal, than in the epileptic convulsion. In puerperal convulsion there is frequently toxæmia, or blood poisoning, with œdema of the extremities. The treatment required in puerperal convulsion is more energetic than that followed in epilepsy. The time for treatment is, in one disease, during the fit itself, in the other, in the intervals. Epilepsy is connected with the ordinary functions of the body, is generally spread over a considerable time; puerperal convulsion, on the other hand, belongs to an extraordinary function of limited duration. Still there are points under which the two diseases very closely approach each other The author of the paper followed these observations by relating four cases which had fallen under his own observation, and a number of other cases which had been furnished to him by Dr. Fleetwood Churchill, Dr. Swayne, Dr. Herapath, Dr. R. Barnes, and Messrs. Higginbottom, Barlow, and R. W. West. The facts of the cases thus detailed showed, that epileptic women are by no means necessarily subject to puerperal convulsions; that in fact they generally escaped this disease; and that the epileptic seizures disappear, or are ameliorated, during gestation. Altogether, the paper contained an account of fifteen cases of epilepsy, in which gestation and parturition had occurred. The deliveries which occurred amounted to fifty one. Of these puerperal convulsions of a decided kind occurred in only two labours, and in one, with a fatal result. In one other case there was an attack of convulsion, with three fits in succession, after the eleventh labour of an epileptic patient, who had borne all her other children without any sign of puerperal convulsion. There was a single seizure in another case, after one of five labours. In all the cases the epileptic seizures had been diminished during gestation, and in some entirely suspended. In one case the fits were frequent during the first pregnancy, but did not appear again during the whole period of child-bearing, though the woman had eleven children. The result of the other inquiries was, that in no case had epilepsy been produced by puerperal convulsions, though he had no doubt such cases might occasionally occur. Dr. T. Smith entered next upon the consideration of the reasons which led to the remission of epilepsy during pregnancy and parturition, examining the several circumstances which might possibly tend to produce this effect. He submitted, that in epilepsy within the child-bearing epoch, the fits are remarkably exaggerated by the catamenial periods, and the ovario-uterine irritation incident to menstruation He cited cases in which epilepsy had occurred regularly at every menstrual period, and at no other times. On the other hand, epilepsy is rare in perfect amenorrhœa, or in chlorosis; in which the catamenial irritation is suspended. In pregnancy, there is the suspension of the ovario-uterine irritation, the arrest of menstruation. To this suspension of irritation the author referred the relief from epileptic seizures during gestation and parturition. He referred to other diseases, depending on or exaggerated by ovario-uterine irritation, such as abortion and hysteria, which diminish, as pregnancy advances, and also dysmenorrhœa, which is often permanently cured by the rest of the ovaria during pregnancy.

Mr. Druitt, while commending the clear and lucid manner in which the author had expounded his views, doubted the propriety of separating puerperal convulsions from other forms of epilepsy, because, although none but infants can be affected with infantile convulsions, and none other than the parturient female can suffer from puerperal convulsions; yet he believed the same state of irritation from peripheral or central sources, or the same condition of toxemia, prevailed in all these cases. He was of opinion, that instances of puerperal convulsions might be fairly compared with those cases of epilepsy which occur from intense irritation, as when a severe fit of epilepsy occurs once, and only once during life, from irritation proceeding from the alimentary canal, from taking indigestible articles of food, or from drinking on an empty stomach. He had met with such cases himself in the country. He (Mr. Druitt) was desirous to ask the members whether they believed there was any connexion between scurvy and puerperal convulsions. A friend of his, in practice in the country, had found scruvy very prevalent during the existence of the potato disease, and he had also found that puerperal convulsions were exceedingly prevalent,—an occurrence which he (Mr. Druitt) thought was not to be wondered at, in consequence of the abnormal condition of the blood, which must have affected the nervous centres. Out of eighty cases of midwifery that he had per annum, there were four instances of puerperal convulsions.

Dr. Murphy had long held the same views as those promulgated by Dr. Tyler Smith. He thought the distinction between epilepsy and convulsions, was not one merely of words, but of practice. He had had cases of patients who were seized with puerperal convulsions, and some had died in consequence, in whom no traces of epilepsy could be discovered. They were strong, healthy young women. On the other hand, he had had cases of epilepsy; in one instance the fits occurred every month, and even every fortnight; and here he had anticipated the appearance of puerperal convulsions, but the patient escaped. One of these patients was seized with puerperal fever, and sunk. The distinction between epilepsy and puerperal convulsions was important in practice, as they might arise in very different conditions of the system; they might be sthenic or asthenic, or dependent on toxæmia, and the treatment that might be adopted properly in one case, would be decidedly wrong in another. The connexion between epilepsy and ovarian excitement he fully agreed in, and thought it explained the way in which convulsions were induced in healthy girls, in the same manner, in fact, in which irritation of the stomach may cause convulsions.

Dr. Barnes, in referring to Dr. T. Smith's views respecting the connexion between ovarian excitement and epilepsy, and the connexion also alleged to exist between the same excitement and the induction of labour, thought that the occurrence of labour and puerperal convulsions, both being under the same law, should be coincident. The fact, that the greater number of the epileptics at the Bicetre practised masturbation, confirmed the connexion between epilepsy and excitement of the generative organs.

Dr. Webster thought that an additional fact, confirmatory of the less frequency of epilepsy during pregnancy, would be found in the fact, that matrimony was often recommended as a cure for epileptics. He alluded to a singular case recorded by La Motte, that of a woman who was free from epilepsy while pregnant with a female child, of which she had five, but suffered from that disease all the while she was in the family way with boys, of which she had three. Epilepsy was much more frequent in France and Italy than in this country, and was frequently caused by masturbation. It was so considered in France and Germany. The conclusions drawn from the paper which had been read were, he thought, very consolatory, especially as the disease (epilepsy) is now very common, much more so than formerly. One fourth of the lunatics in the metropolitan asyla (4000 in number) were epileptic.

Dr. Cape agreed with those who marked a distinction between ordinary epilepsy and epilepsy in the puerperal state. There was a great similarity in the seizure, but the treatment was different. Children and men, and women when not pregnant, were subject to epilepsy; pregnancy, indeed, was believed to diminish the tendency to epilepsy. He (Dr. C.) inquired respecting the relative frequency of epileptic attacks during the night and day, and mentioned the case of a lady who was seized with epilepsy on her wedding night. Her husband was greatly surprised, and reproached the friends with having concealed her liability to this disease, while they, on the other hand, denied all knowledge thereof. It was not impossible, he thought, that she might have had the fits during the night, without the fact being discovered. There was not any subsequent recurrence of the fits during gestation or delivery, although she had several children afterwards.

Mr. Barlow thought the case mentioned by Dr. Cape was very interesting. There could be no question as to the greater frequency of epileptic fits during sleep; several instances of that had recently come under his observation. It was perfectly possible that the friends of the lady were unaware of her liability to epilepsy, as the fits might occur during the night for a long while without being discovered, unless by some such a symptom as a bitten tongue, a bruised finger, &c. Notwithstanding the fact that epilepsy is not followed by puerperal convulsions, nor the latter succeeded by chronic epilepsy, he thought that the puerperal convulsions only differed from the other disease in being more aggravated, the symptoms being the same, and a bitten tongue occurring as frequently in the puerperal as in the non-puerperal form. There

are not any grounds, he believed, for saying it is not a form of epilepsy. It resembled, as Mr. Druitt had said, that form of epilepsy, which occurs but once during life, from the irritation produced by a disordered stomach. Of this kind of epilepsy, he (Mr. Barlow) had seen several examples, one lately from eating bad fish. With respect to the state of the patient between the intervals of the fits in epilepsy, the patient is completely comatose. In the case of a young woman who had had repeated and very severe paroxysms lately, the attack extending over several hours, and at last ending fatally, there was deep coma between each paroxysm, every one of which was ushered in by a crowing sound such as, if it had occurred in infants, would have conferred on the disease the name of laryngismus stridulus.

Dr. Robert Lee mentioned the case of a lady he had been called on to visit, in consequence of an attack of puerperal convulsions. She had subsequently distinct epilepsy, occurring at stated intervals. He had notes of from forty to fifty cases of puerperal convulsions. Of these, there had been epilepsy in early life in three instances, in several hysteria, and in one chorea, which occurred at the sixth month, and passed into puerperal convulsions, after the expulsion of the contents of the uterus. The case terminated fatally, and the autopsy showed there was not any disease in the brain. He (Dr. Lee) considered chorea, hysteria, epilepsy, puerperal convulsions, and puerperal mania to be allied, but still distinct diseases. They might exist without the occurrence of any organic disease.

Dr. Willshire, with reference to the distinction between epilepsy and puerperal convulsions, remarked, that the aggregate of symptoms and pathological lesions, was the same in both cases, and the only distinction was in the cause; but as the cause could not be regarded as making a difference in the disease, he did not consider that there existed any real difference between the two, as they were identical in symptoms, and in their pathological phenomena.

Dr. Manson remarked, that it appeared from the observations that had been made, that convulsions were always due to irritation of the central organs, or of the periphery. The mind itself, however, might be productive of such an effect, of which he had seen an illustra ion in the person of a child, two years old, who had been frightened by a mask, was taken home seriously ill, became violently convulsed, and so died. The body was not examined after death. Epileptic children, if suddenly awakened from sleep, are very liable to be seized with a fit. He had seen a case of very violent convulsions, which occurred after the exhibition of chloroform, and after severe hæmorrhage from the partial separation of the placenta. To which of these causes the occurrence of the convulsions was due, he (Dr. Manson) was unable to say.

Dr. H. Bennet observed, that great stress had been laid on the connexion between uterine irritation and epilepsy,—a connexion which he, although having had great experience in cases of uterine disease, had failed to notice. It was not a common sequence of uterine irritation or disease. Out of 300 cases of disease of the uterus mentioned in the appendix to his book, there was not one case accompanied by epilepsy. As again, on the other hand, epilepsy is very common among males, in whom no such monthly excitement takes place, we may fairly conclude that uterine derangement has very little to do with the outbreak. Holding that opinion, there cannot be any surprise that epilepsy is not followed by puerperal convulsions. At the Salpêtrière, there were 500 incurable epileptics, sent in from other hospitals, and they gradually fell into idiotcy and mania. While he was interne there, he had not noticed any especial prevalence of uterine disorders among these patients.

The discussion was then adjourned.

The Directors of the York and North Midland Railway Company have presented 125*l.* to the Railway Fund of the York County Hospital.

CORRESPONDENCE.

NATIONAL MEDICAL ANNUITY AND RELIEF FUND SOCIETY.

LETTER FROM MR. DANIELL.

[To the Editor of the Medical Times.]

Sir,—I feel some hesitation in addressing you relative to the above Society, because it is impossible to arrive at any safe conclusions respecting it until the Managing and Provisional Committee shall have furnished their final Report.

To comment at all upon any measure which is simply in progress, and not publicly declared, otherwise than in the form of suggestions, is to my mind a questionable procedure.

If we are satisfied, the parties employed in an investigation are competent to the task, and if we believe that their standing in society places them, like Cæsar's wife, above suspicion, surely it becomes us to wait quietly the issue.

Your own remarks, and the letter of Dr. Webster, force me, however unwillingly, to say a few words.

I do not think, Sir, that either you or your readers are exactly in a position to judge of this matter; nor are you aware of the peculiar circumstances which rendered a change in the original plan imperatively necessary. In my opening observations at the Hanover-square Rooms, I endeavoured to explain the reasons, but the report of that meeting was not extensive enough to give the required information.

The fact, that the "Proposals" for the establishment of a "General Medical Annuity Fund," were made at a meeting of the Provincial Medical and Surgical Association, and intended to form an integral part of that body, was sufficiently stated; and, moreover, that an Act of Parliament had greatly interfered with the project, as a separate and independent institution, but the whys and wherefores were not stated. Now, that Act of Parliament, passed subsequently to my "Proposals," demands stringent regulations, statistical and correct data, and tables formed by a properly-authorised actuary. These were matters that never entered into my mind, nor the needs be for enrolment did I contemplate, on the first promulgation of my views. Sheltered, as I hoped the Society would be, under the wings of that important and excellent Institution, the Provincial Association, I entertained no fears for its security, no doubts as to the safety of its funds, nor to the just distribution of its dividends. Now that it has become separate and distinct, there is an absolute necessity that it should, in all its details, conform strictly to the letter of the law, since the law must, in every sense of the word, be its protector. You are not ignorant, Sir, of the difficulties under which those "Friendly Societies" labour, the rules of which preclude the possibility of enrolment. On how many occasions have the Society, called "Odd Fellows," suffered by the peccantry of nefarious members, without the least power of punishing the wrong, because, being what is called a secret Society, they were unable to place themselves under the protection of the law. I have been at considerable expense and more trouble, to ascertain how far the Society which I had organized could be protected; and, from the opinions of learned lawyers, as well as from the statement made to me by distinguished actuaries, I gathered, that under the "rules and regulations" then existing, there was no chance of the Institution receiving that protection, without which, as an honest and conscientious man, I could not continue to ask support.

It was this fact which determined me to seek assistance in London; and it was this fact which directed me to draw up the "resolution" to which Dr. Webster has referred.

I must beg, sir, to demur to the statement, that we are forming a *new* Society—we are doing no such thing. We are simply remodelling the Institution, to render it conformable to the law. It was a self-supporting Society which I advocated—*not a charitable one.* It is true, that under one head, I combined co-operation and benevolence; but, mark you, even those, who in the first instance might contribute their money as a simple act of charity, were still eligible to become recipients, if adverse circumstances compelled them to become applicants; and who is he that can defy fortune, and say that neither he nor his offspring will ever need the helping hand? The man on the woolsack may carry a wallet—the world is full of histories of humbled greatness—of kingly beggars.

The "Report" to which you have alluded has shown that I was in error as regards my calculations. I bow to the "Report," for I regard it as a splendid indication of the talent and ability of the parties by whom it was framed. Neither am I mortified by the manner in which it has handled my project; for what is my aim? Not victory, but truth; not to establish a false principle, but to seek out one that shall be stable, let it spring from what source it may. The true principle by which I have been actuated, is pure in its original integrity: the error is in the action: Plato says, and says justly, "Better to err in acts, than principles." You, Sir, like me, have seen the necessity of establishing a National Institution for our decayed brethren and for widows and orphans. Many excellent papers have appeared in your Journal, advocating an Institution for this purpose; thus I take it for granted our *principles* are identical,—let us hope there will be an identity in our actions also. This is not a time to fritter away opportunities, or allow of either party feelings or party prejudices. Thank God! the ground is neutral; and the aim—to ameliorate sufferings amongst medical Practitioners, whether they walk in the aristocratic circle, or their field of operation be confined to the humble or the low. We can afford to lose no assistance—whatever views, or whatever opinions men have, let us have the advantage of them, that by our combined energy, good may be done. Never was that old nautical maxim more needed than now:—

"A long pull, a strong pull, and a pull altogether!"

It requires neither the force of eloquence, nor the exercise of shining talents, to prove the *necessity* of the institution we contemplate. Facts, of the most startling import, have intruded themselves upon us, and cases so singularly touching in their awful reverses come upon us like dark clouds dimming the medical horizon, that who can behold them unmoved? Fancy a physician dying at Liverpool, without sufficient effects to purchase a coffin or a grave; and mark the exit of Walker of Manchester, of Howell of Bath,—men who rose upon us like dazzling meteors, because of the brilliancy of their talents, and like meteors, alas! shone but too briefly. It is well known each of these gentlemen did not live long enough to make provision for their helpless widows, and still more helpless children.

Inquire into the fever districts, where the Irish plague revelled so freely, and, still later, enter the homes of many of those active and enterprising men, who, with noble devotion, strove to mitigate and arrest the fearful pestilence, now hardly stayed amongst us. Are there no widows, no orphans to be found there? I trow yes. Widows, plunged from comparative prosperity to the depths of indigence and sorrow. Children deprived of their parent head, partially educated, refined in feeling and in thought, shrinking as it were before the rough blasts to which they are so painfully exposed. If the true seeds of knowledge have been sown, how ardent is the thirst for further acquisition.

"But knowledge to *their* eyes, her ample page,
Rich with the spoils of time will ne'er unroll,
Chill penury repressed their noble rage,
And froze the genial current of the soul."

To overcome these fearful calamities, to provide against such contingencies, is the great aim of those who have hitherto been associated with me in the establishment of an "Annuity Institution," and I am equally and firmly convinced that such is the object of those gentlemen who are now giving their time and attention in weekly meetings to this subject. I sincerely hope, Sir, their valuable services may not be lightly considered. Whatever opinions other parties may entertain as to the best mode of accomplishing the object we have in view (and I, for my own part, reverence and respect every man's opinion, honestly and freely given), I implore them to believe, that if their aim be good, we are not so wedded to our own projects as to deny to them a legitimate hearing or a legitimate inquiry. Human judgment is fallible always; but there are approaches to perfection, and towards that condition we gladly hasten.

What is done, then, let it be done in the true spirit of co-operation, avoiding all that is personal; seeking but the advancement of a fixed and permanent good; bearing in mind that the well-being of the widow and orphan *must not* be jeopardised by any division unworthy of ourselves.

There is a great stake at issue. A noble Institution to be re-organised, which may not only benefits the present generation, but shall extend its blessings to all posterity.

My hope and prayer is, that we may go to this undertaking in the true spirit of Christian love, in that "charity which suffereth long, and is kind, vaunteth not itself, is not puffed up, not easily provoked, thinketh no evil, beareth all things, believeth all things, hopeth all things, endureth

all things." If, like a holy mantle, we seek to cover ourselves with this spirit, then will God's blessing rest upon our labours, for we shall have "one heart and one mind," and our determined resolutions will never flag, until the great and glorious object be achieved—that object which has upon it, in an especial manner, the benedictions of the Most High.

I am, Sir, your obedient servant,

EDWARD DANIELL.

Newport Pagnel, Dec. 24, 1849.

LETTER FROM MR. ROSS.

[To the Editor of the Medical Times.]

SIR,—I must confess that I was somewhat surprised to find, on perusing your Journal of last week, that the aspiring President of the defunct British Medical Association had made me, through yourself, the object of his unmannerly hostility. It is difficult to say in what proportions his censures should be appropriated, so dexterously has he contrived to implicate two individuals in the culpability of one crime. I have no doubt that you have smiled at the artfulness of the assault, as much as I have at its petulent asperity. It is certain, however, that no shaft was ever forged in the Dulwich armoury, with a point keen enough to pierce the skin of the most sensitive publicist; and even though it should be tipped with gall, and feathered with malice, it would require a stronger arm than the doctor's to send it to its mark, and to impregnate the character of an honest man with its venom. I will not condescend to the vulgar personalities which Dr. Webster has directed against me; for, although by his adoption of this species of attack, he may deem that it is becoming to his character, I can assure him that it would only disgrace mine.

What have I done, Sir, to call down upon me the injurious insinuation and evil-working insult of Dr. Webster? Your reporter was present at the General Meeting of the Medical Annuity Society,—I call upon him,—I call upon Dr. Forbes, the Chairman, or upon any gentleman who was present at that meeting, to declare whether I used a single phrase, in the course of my remarks, that could be construed into a personal reflection upon any member of the Profession? Was there, in particular, a single word censorious of Dr. Webster? If there were, why did not Dr. Webster, or some other individual, repel the offensive accusation at the time and on the spot? Again, Sir, I ask your readers, what expression there is in that exceedingly dry and brief epitome of my speech published in the *Medical Times*, that can be considered, in the slightest degree, of an injurious personal tendency? There is nothing of the kind, and Dr. Webster knows it; although—but I will not lay another man's heart under the scalpel of criticism, and dissect all its disguised motives. The occupation were an ungracious one, and would not repay the trouble. Every candid man will promptly admit, that Dr. Webster's epistle, in which he infers that your leading article upon the subject of the Medical Annuity Society was written by me, whom he further describes as a "disappointed person," governed by "vanity and self-love,"—for I have too much contempt of calumny to hesitate to accept a slander which is intended for me, but which the author of it dared not openly to pronounce,—is the channel of a gratuitous and unprovoked insult; and although, as a man and a public labourer, I am entitled to repel it with chastisement, I prefer to forgive the offence, and to regard it as an indiscretion of which the learned gentleman himself, if he have any sense of shame, has, by this time, heartily repented of. The aspersion can do me no harm, although, by singling me out for an opponent, Dr. Webster may acquire the notoriety he covets, and do himself some service.

I must now claim your space, Sir, to contradict the mis-statements in Dr. Webster's letter; and, inasmuch as that gentleman has shown a fretful sensitiveness in respect to your charge of mis-statements appearing in the Report of the Sub-committee, I trust that if I can substantiate a similar accusation, founded upon the assertions in his own letter, a fair presumption will be established, that your allegations in reference to the Report were correct; for it can scarcely be assumed, that any two men could be found guilty of precisely similar misrepresentations.

Dr. Webster has stated, that I failed in the object of my speech, and that I stood alone in the views I professed. This is not wholly correct. I willingly admit that no following speaker supported my sentiments, nor did I expect that any would; for my experience of public business has convinced me that no single individual can succeed in gaining much sympathy for antagonistic opinions, or in reversing the decisions of a Committee in any public meeting, even although larger than that at the Hanover-square Rooms, at which, I should think, more than three-fourths of the members belonged to the Committee, and nearly one-half to the Sub-committee, who, in mere consistency, were pledged to the statements contained in their printed Report. I wrote to Mr. Daniell, expressing my conviction that I should stand alone in the position I intended to take up, and I have more satisfaction in making a sacrifice for the integrity of my own understanding than any man can have of a feeble subserviency to the views, right or wrong, of other men. That I failed, however, is a bold and an untrue statement. Powers were given to a Provisional Committee to carry out the resolutions of the meeting, with "such modifications" as might be deemed expedient, and it was specially suggested to me, before the resolution was put, that this qualification would meet my views, and it was upon this ground alone that I consented to my name being placed upon the Provisional Committee. Does Dr. Webster wish to deprive every gentleman of the right of expressing opinions at variance with the conclusions of a governing body? or, does he think that it becomes every man who desires to offer counsel to assume the attitude of a bully, to move amendments without end, and to carry on a factious opposition to every proceeding not accordant with his own opinions? If so, the Profession have discovered the key to many an act in the Doctor's political career.

Again, the Doctor says that Mr. Daniell "has tried the scheme" that I propounded, and he seizes the opportunity to stigmatise me because of Mr. Daniell's failure! Generosity and truth are equally despised by the man who could deliberately write the sentences conveying these imputations and assertions. The statement that my plan and Mr. Daniell's are the same is contradicted by the whole tenour of my arguments, and is wholly inconsistent with the brief report of my observations given in the *Medical Times*. Let the facts speak. In the first place I declined to join Mr. Daniell's society, although the subject had been urgently and repeatedly brought under my notice by that gentleman, because I felt assured that the plan of the Society was faulty, and that it must eventually fail; and I would not be responsible for recommending to the Profession a scheme which might, however unintentionally, "deceive by false hopes;" and, for the same reason, I opposed the projects of the Sub-committee, which, by running into an opposite extreme, were equally repugnant to my views. In the second place, I actually complimented the Sub-committee for advising the separation of the Fund for Widows and Orphans from that for Disabled Members,—the union of which was the cardinal error in Mr. Daniell's scheme; and yet Dr. Webster directly accuses me of this absurdity! This separation effected, I maintain, now as then, that the principle of a small premium for an annuity, contingent upon the nominee's possessing a certain amount of income, so as to constitute an absolute security against destitution, is a far better principle to meet the exigencies of the less fortunate members of the Profession than that proposed in the Report. This is an opinion, and, even it wrong, I ought not to be undermined by misrepresentation or assailed with invective. The bad taste that could be guilty of either deserves my compassion and has it.

Dr. Webster again says, that I contended "for an institution that should be partly supported by an annual payment of one guinea, and partly by the charity of the public and the richer members of the Profession." I deny it. I uttered not one word about "the charity of the public" during the whole evening, and never intended that it should form an integral constituent of the plan I then outlined. If Dr. Webster wish it to be inferred, that charity is a necessary condition of such a scheme as I ventured to discuss,—and this is all that he can mean,—then I presume that my arguments were not understood by him, or, if understood, thought of no value; or, if thought of value, purposely rejected, that he might not lose an opportunity of indulging in his very facetious humour, and of reiterating a taunt which he thought too good to be lost. How can that be considered a system of charity which confers an eligibility for the benefits of the Society only on those who are enrolled members, and have subscribed regularly to its funds? It is the performance of this compact that gives every member, or his nominee, an *equal right* to an annuity; and this right can be qualified, or lost, only in accordance with certain other terms of the compact, to which all parties, on entering the Society, give their unconditional assent. Charity, indeed! Because one man loses a right, in compliance with a written engagement or law, another man, who simply preserves his original right, becomes an object of the disqualified's charity! By a similar species of argument, it might be proved, that each honest man owes his civic rights and liberties to the charity of some fettered rogue, who suffers incarceration and the whip from a loving purpose towards his fellow-men. This is a logic at which Scotland should blush for shame, and cover her head with ashes. It is very clear, that a penetrating genius of this kind is not sufficiently honoured by the task of establishing an Assurance Office.

Another assertion which the Doctor makes is already refuted. He says, "Several gentlemen *did reply* to them, (my arguments,) and that to the satisfaction of the meeting," &c. If my arguments were replied to, they certainly were not answered; but I maintain, that the assertion is totally incorrect. One gentleman, I admit, got up a sham display against me, by setting up the bugbear of benevolence,—in fact, precisely the same topic that Dr. Webster has assumed as my weak point,—and he endeavoured to fix upon me the responsibility of this principle. I disdained to notice publicly this palpable misrepresentation, as I did not imagine that any one could have been deceived by it, and I did not desire to extend an unprofitable discussion. That Dr. Webster should have adopted the same I had almost said unscrupulous system of dialectics, only proves, that, when men have once acquired a prejudice in favour of error, they love it for its own sake, and will not take the pains, if they have the inclination, to set themselves right. I assert, however, that the mis-statements which I pointed out in the Report remain to this day unexplained and unanswered.

One more remark, ventured by Dr. Webster, also demands notice, as it is made the medium of an attempt to cast a stigma upon myself. The Doctor says, that Mr. Daniell showed "rare magnanimity and singleness of purpose," in abandoning his old scheme for a new one. To this I have only to remark, that if any man be convinced that his opinions are false, it is his duty to relinquish them; but if, on the other hand, he believe them to be right, and renounce them in mere acquiescence with the representations of other men, he is guilty of treason to his own conscience and to truth. Mr. Daniell is a man whom I so highly respect, that I would refrain from loading him with ostentatious eulogies, as they might only impede him in his future career of usefulness. I am sure, that among his other estimable qualities, he possesses the manliness not to suffer his name to be made the vehicle of slander towards either a private friend or public opponent. I now take leave of Dr. Webster's letter, with but one doubt on my mind, that I may have reflected too much importance upon its puerile obloquy by stooping to notice it with so much minuteness and conventional toleration.

Fear of occupying too much of your space prevents me from entering upon an analysis of the Sub-committee's Report, as I had intended; but, if Dr Webster be discontented with this letter, I shall be glad to write another upon the same subject, and I hope that I shall then acquit myself more to his taste and satisfaction. I now repeat, that there are numerous mis-statements in the Report; but I am quite willing that the document should remain entombed in the sepulchre of its own worthlessness, whence, I am well convinced, no individual but Dr. Webster will think it worth his while to drag it forth with all its sins upon its head.

I am, Sir, your most obedient servant,

GEORGE ROSS.

THE RIDGWAY-HOUSE ASYLUM.

[To the Editor of the Medical Times.]

SIR,—I am obliged to you for proposing to allow me the use of your columns for the purpose of setting myself right with the Profession and the public as to the abuses reported to have been found in my Asylum by the Chairman of the Gloucester Quarter Sessions.

I deny most positively that such abuses have existed, or that anything has been observed in my Asylum, or in reference to my patients, which would have called for notice in the public report of any considerate and well-intentioned visitor.

It is about twenty years since my attention was more particularly directed to the treatment of insanity, and during the greater part of that time I have received a limited number of patients in a licensed house. The object that I have kept more particularly in view, and which, indeed, was one of my main inducements for entering on this branch of practice, was to ascertain and to demonstrate how much the ordinary treatment in asylums might be improved upon, and how much restraint, and the

appearances of restraint, those appearances which form repulsive features in many Asylums, might be advantageously dispensed with. It was my practice, therefore, to receive my patients as friends and visitors in my family, and to endeavour in all cases to exert an influence over their minds by uniform attention and kindness, tolerating their presence in the family circle whenever it was possible to do so, and subjecting them to no restraint in general, beyond a temporary retirement in their private rooms when requisite. The results of this treatment, and many circumstances connected with it, would not be uninteresting to your readers, and I may possibly, at some future time, bring them before the public. It will be sufficient for my present purpose to state here that every patient I had for several years under my care, expressed, more or less perfectly, according to the mental state of each, his or her satisfaction and gratitude for the kindness received. Every patient, I believe without exception, who has left my care (unless Mr. Hayward, who is mentioned in your paper, should still be sufficiently under an adverse influence to withhold it) would now give his testimony in the strongest terms. But its truth may be inferred from a simple fact, which speaks volumes. Several of my patients, after more or less perfectly recovering, have preferred making my house their permanent residence, some of them for years, and have finally left it with expressions of the deepest regret. And others voluntarily, and entirely of their own accord, placed themselves under my care, of course without certificates, or being liable to restraint. It was not illegal, before the passing of the late Act, for persons thus voluntarily to remain in, or to enter licensed houses, though the Commissioners objected to it as a practice liable to abuse, and the late Act has made it penal. Doubtless the opinion of the Commissioners is entitled to great respect and deference, and was probably formed from a consideration of the circumstances of many Asylums, and the difficulty of framing and enforcing regulations to prevent anticipated abuses; yet it may be questioned whether, in obtaining the above-named enactment, they have not given a fatal blow to the greatest improvements of which Asylums are capable.

Without, however, entering on the arguments *pro* and *con* in this place, I must proceed to state, that the discussions on this point, and the interruption of my plans, on the success of which I had justly prided myself, both by the interference of the authorities, and especially by the passing of the new Act, rendered it necessary that I should make some important changes in my establishment; and thinking that, on several accounts, a residence near a great city would be advantageous, I was led to take Ridgway-house, near Bristol, an Asylum which had been established many years, and whose then proprietor was disposed to retire; and the neighbourhood of which enabled me to secure a private residence suitable for my family, and a limited number of nervous invalids, or other friends, who might wish to reside under my roof. Here I hoped to be able to carry out my views and plans successfully, (as, indeed, I did for the space of about three years,) little expecting to meet with the extraordinary and most unwarrantable interruption that I have lately done.

I must here state, that, although Ridgway-house had been licensed for many years, it was not in itself in a satisfactory state for the purposes of an Asylum, some parts being old and incommodious, and the whole requiring great alteration and improvement; but the conveniences of its situation, its healthiness, and retirement, the beauty of the surrounding scenery, and the extent of land, consisting of about fourteen acres of garden and grounds attached to it, decided me to undertake its occupation, with a view to make the necessary improvements; and it was my intention to begin those improvements on my taking possession. This, was fully known to the Visiters; and builders in the neighbourhood can testify, that one of the first things I did was to obtain tenders for the re-building of part of the premises. Circumstances, however, prevented me from making the arrangements necessary for that purpose, until I had had possession for nearly three years, when I succeeded in purchasing the property, and immediately began to carry my plans into execution by the erection of a new wing to the house. My intention to re-build those parts of the house which were the most old-fashioned and least convenient, prevented me from doing more than was necessary to make them comfortably commodious for my patients, while those apartments which had been usually occupied by the family of the proprietor, furnished accommodation for the better class of patients. I even gave up my library, and occasionally my own bedroom, when pressed for room, for their use.

Three things require to be particularly noted here:—In the first place, I had discontinued the use of some of the more objectionable apartments, which had been formerly occupied by patients, and had greatly improved their accommodations altogether, as the Visiters invariably and decidedly testified. Secondly. The patients were all perfectly satisfied and comfortable in their apartments, and received such care and attention, as made them generally happy and contented, and promoted the recovery of several that were curable. Thirdly. The state of the house had been uniformly remarkably healthy during the whole of my residence in it.

Now, it is important to mark these circumstances, because it was just at this critical period—a new wing being half erected, and the house in this transition state—that Mr. Purnell made his first visit.

It will be easily understood, that, to the fastidious eye and prejudiced mind of an individual, whose evident object was to find fault, and to make startling and astounding reports, many things in such a house might appear objectionable, and afford food for invidious remark; and so, accordingly, Mr. Purnell did not neglect the opportunity of furnishing himself with many topics of complaint. But I would ask, whether any discreet, judicious, and right-minded man would have deemed it proper to make any report at all in such a case? What was his object?—to improve Asylums? Here he had found one more effectually bent upon that object than himself, inasmuch as, while *he* was only vapouring and producing excitement, the other was setting about, in good earnest, to lay the foundation of substantial improvements.

Would any sober-minded man have attacked and abused, and made publications detrimental to the interests of a person so employed, and of his establishment?—publications tending to damage his reputation, and effectually to cripple him in his progress.

It was in this description of Ridgway-house that the passages occur which you notice; if there were no fixed baths in the house, Mr. Purnell might have felt assured, or might have ascertained, if he had any doubt, that such were included in my plan of improvement.

The history of the hen laying her egg in the moveable bath, was too trifling a circumstance to be gravely noted, and recorded; but, if worthy of notice at all, it should have been ascertained and stated, that it was a freak of the patient's, Mr. Hayward, who being indulged, as far as possible, in all his fancies, was allowed to keep fowls and rabbits in a court adjoining to a carpenter's shop, which he also used; and, as the bath was kept in an apartment through which he passed to his shop, he, indulging his propensity to turn things to uses for which they were never intended, had slyly made a nest in it for one of his hens, and thus furnished a notable incident for a Visiter's report!

The next statement respecting Mr. Hayward, that he was confined in a close and offensive room, is retailed upon his own authority, and would have been disproved by the attendants and others in the house, if the object of the inquiry had been to elicit the truth.

That the Chairman should, in his last report, have again ventured to say, that he was "strong in body, and sound in mind, as many witnesses can testify," after he had himself stated the evidence of Dr. Green to the contrary, and after proofs innumerable had been given to the same effect from a variety of sources, does seem inexplicable on any ordinary principles of reasoning or conduct.

You seem to adopt the Chairman's notion, though you have probably not considered the liberal sentiments, and the decent and respectable compliments to the Medical Profession, on which it is grounded and enforced, that no medical man, keeping an asylum is fit to be entrusted with the medical care and superintendence of his own patients; and you seem to lose sight of the fact, that all the great modern improvements in treatment have been brought about by medical superintendents of asylums; and if further improvements are to be looked for, as it is to be hoped they are, the first enactment of the Legislature should be the prospective exclusion from the conducting of asylums of all but medical practitioners. But, then, let me ask, what medical man would consent to take such a charge, especially if it was a pursuit he took up *con amore*, and from benevolent and praiseworthy motives, if he were to be made by law an inefficient cipher in his own establishment? It is easy for crotchety and superficial individuals, who are capable themselves of doing nothing with propriety or common sense, to make crude suggestions for the regulation of establishments respecting which they have no experience. But it is a pity such notions should be adopted by respectable and influential persons.

What I have to complain of is, that Mr. Purnell has, with an unfairness most reprehensible, classed my asylum—and has pointedly and repeatedly gone out of his way to do so,—in which, with all his inquisitorial researches—he could find no case of unkind or harsh treatment of a patient,—with other asylums, in which he alleges, whether truly or not, that such treatment prevails—that he has taken the unsupported statements of insane, weak-minded, and interested individuals, and has founded his report upon their unworthy testimony, and, not only so, but that he has eked out, and made up their deficiencies according to his own prejudiced views, by his own inferences, insinuations, and conjectures. That his inferences and conjectures are every one mistaken and unfounded, and that his reports, professing to relate facts, degenerate into foul and calumnious libels upon myself and other unoffending persons; that when the true state of the case has been pointed out, and has been even proved, or proof tendered, Mr. Purnell has not been willing in any respect to correct his views, or to withdraw and modify his statements; and that, when I have appealed to the other visiters or the magistrates in sessions, they have acted upon the resolution, that it was better for them to support their Chairman, even in wrong doing, in injurious oppression and cruel misrepresentations, rather than do an act of simple justice to a persecuted individual. That finding such to be the case, I have thought it necessary rather to give up my license, and break up my establishment, than to continue subject to the invidious reports, and the insolent and overbearing conduct of persons, whose behaviour in my house towards my inmates and myself, has been the reverse of every thing that was becoming in magistrates, gentlemen, or men.

Conscious of no wrong towards any of my patients, having invested my property in an asylum, and having devoted myself to a pursuit towards which I was originally attracted, and to which I had become, by habit, much attached, from motives very different I hope from those attributed to me by Mr. Purnell, and which he probably can neither appreciate nor understand, I have made a sacrifice—I have given up my pursuit, rather than maintain a position in which I was subjected to insults and injuries, which no man of gentlemanly feelings could longer tolerate.

Mr. Purnell, in the course of his inquiries at my house, has, in my opinion, done the most injurious thing possible to two unfortunate individuals whom he caused to be liberated from salutary restraint. A brief history of these persons, and of the circumstances connected with their discharge, I will, with your permission, make the subject of a future communication. In the meantime, I hope that what I have above stated, will induce your readers to suspend their judgment, as to the accuracy, the good sense, or the utility of Mr. Purnell's reports and labours.

I remain, Sir, your obedient servant,

GEO. S. OGILVIE.

Ridgway-house, Dec. 19, 1849.

[The Report of the Gloucestershire Magistrates is either true or it is not. Coming as it does before the public stamped with authority, it is calculated to produce an impression on the public mind anything but favourable to private asylums. If the statements made concerning Mr. Ogilvie's establishment have been made without regard to truth, we hope that gentleman will speedily set himself right with the public and with the Profession, and we shall feel great pleasure in affording him all the assistance in our power.—ED. *Med. Times.*]

ON THE USE OF HYDROCHLORIC ACID IN CHOLERA.

[To the Editor of the Medical Times.]

SIR,—I consider it the duty of every medical man to state, in these awful visitations of cholera, the treatment he has found in his own practice most efficacious in this dreadful disease. Under this conviction, I shall make no apology for troubling you with the statement of my own experience, in the hope that others may be induced to adopt similar treatment, and as I conscientiously believe, mitigate, if not wholly relieve, much human suffering, and arrest the hand of death.

When cholera first made its appearance in this town, I, being Surgeon to the Bridgwater Union Workhouse, had many cases under my care of

malignant Asiatic cholera, for which I tried the various remedies most approved by the Profession, but confess with most unsatisfactory results. Under these circumstances, I was induced to attempt the investigation of the disease by the examination of secretions and excretions of diarrhœa and choleraic diarrhœa, and found a marked difference between them, those of the former being acid, the latter alkaline; and that, by the aid of the microscope, crystals of the triple phosphates of lime were observable in those of choleraic diarrhœa. These crystals are ably depicted by Dr. Brittan, in his late paper on "Choleraic Bodies," published in the *Medical Gazette*. Finding, from experience, that, when these crystals are observable in the urine, they have disappeared by the use of hydrochloric acid, I determined on giving this acid a trial in cholera, inferring that, if alkalines were useful in acid diarrhœa, acids may be likewise so in alkaline diarrhœa, which is Asiatic cholera.

The formula used in 23 cases of cholera and choleraic diarrhœa was—℞ Acid hydrochloric, ℈i.; tinct. opii; aquæ, ℥vij.; chloric æther, ʒiij. M. ft. mist. Two tablespoonfuls to be given every half hour, with one grain of calomel, if the case were severe, or when the cases were less severe, without calomel every two hours, as long as purging and sickness continue. The result of this treatment has been three deaths, and although these fatal cases were considered hopeless from the commencement, yet relief was experienced by the use of the acid mixture, and the others rapidly recovered without fever, which so frequently follows other modes of treatment.

Should this treatment be thought worthy of a trial by the Profession, a report of the result, either in your most useful Journal or to me, will greatly oblige,

Sir, yours truly,

ABRAHAM KING.

Bridgwater, Nov. 15, 1849.

P.S.—Mr. Heard, chemist, of this town, has suggested the *modus operandi* of this treatment, viz., that the alkaline state of the system affords a solvent for the acid, making common salt, which supplies the serum of the blood with that salt which is so suddenly abstracted by the disease.

MR. McCLURE AND THE CHOLERA IN PLYMOUTH MARINE BARRACKS.

[To the Editor of the Medical Times.]

SIR,—As Surgeon having the Medical charge of the Plymouth Division of the Royal Marines, I feel myself called upon to correct mistakes made by Mr. McClure, Assistant-Surgeon, R.N., at page 473 of your Journal of Saturday last, where, in a paper on the cholera at Torpoint, Devon, he imputes neglect of due precaution on the part of the medical officers, and, indeed, of the officers in command of the division.

I beg to state, that every means that human foresight and knowledge could devise was adopted to prevent the spread of cholera spasmodica. Colonel Fergusson, the Colonel Commandant, on the appearance of the disease in the district, ordered every object which was likely to form a "nucleus" to the cholera to be removed from the barracks; the drains were flushed three times a week, and a plentiful supply of lime was furnished for these localities on all occasions, and, at certain points, the chloride of zinc was used. The whole of the men of the battalion were paraded and narrowly inspected three times a day. I explained to them the necessity of reporting any symptom of disease (and especially in regard to bowel complaint) with which they themselves, or their families might be affected, without delay, to the medical officers.

The men's quarters in barracks were inspected three times a day by commissioned officers specially appointed for the purpose, and the private quarters of the men living in the towns were examined each day by the commissioned officers of the respective Companies, who directed whitewashing in the rooms, which was performed twice a week, with lime supplied by the Commandant, and on all occasions the commissioned and non-commissioned officers were directed to report any man who looked ill or complained.

Mr. Kevern, Surgeon, R.N., and the Assistant-Surgeon, Mr. Kay, R.M., by judicious arrangements, were, in the private dwellings in every quarter, supplying the chloride of zinc, and giving information respecting ventilation, &c.

The diet of the men in barracks was increased and changed, free ventilation was carried out under my own inspection, and, by the addition of the chloride of zinc to the ordinary means of cleaning, the state of the rooms was such that the most fastidious could not have found fault. The bedding was aired on such occasions as the weather and the duties of the battalion permitted; in short, every means was used to keep the men of the battalion as much as possible under the superintending eye of the commissioned and non-commissioned officers, and, as is usually the practice where troops are stationed during epidemics, orderlies were selected from the most experienced and steady men to prevent straggling into infected districts, and to guard the privies.

As regards the men being carried into the Naval Hospital in a state of collapse at the beginning of the epidemic, I have to state that such was not generally the case, as a great part of the men were willing, and many quite able to walk into the Hospital; and some who ultimately died of cholera actually did walk there, being at the time merely affected with diarrhœa, which, however, merged into cholera, after admission. Every effort to avoid delay was used by Mr. Kevern, Surgeon, R.N., and Mr Kay, Assistant-Surgeon, R.M., in conveying the men attacked if different, and sometimes distant parts, to the Naval Hospital.

I am at a loss to know from whom Mr. McClure derived his knowledge of the hygienic regulations of this battalion, and it would have been better had he made himself acquainted with this subject, previous to bringing it before the public.

The average strength of the battalion, during the epidemic season, was 1,267. Of the total, 2·56 per cent. were attacked with cholera. 523 resided in Stonehouse barracks; of these, 2·86 per cent. were attacked in their barracks; 163 resided in Mill-bay barracks; 6·13 per cent. were attacked in their barracks; 60 were officers, 385 were married men in private quarters in the towns; 136 were in sick quarters and on leave of absence; of this total, 1 2 per cent. were attacked. Six men were attacked when on duty in various situations, giving a per centage of 47 to the total strength.

Between four hours and a half, p.m., of the 9th, and seven hours and a half, a.m., of the 10th of August, eight men were attacked with cholera in these barracks, and again, two on the 12th, and four on the 13th, and one on the 24th of the same month. These men had undergone the inspections of the parade and their rooms, amounting to six times during the twenty-four hours, without exhibiting signs of illness, and I believe had no premonitory symptoms, beyond those reported by me to the inspector of Hospitals.

With the exception of the sick and those on leave of absence, every man came under the serveillance of the officers in the discipline described.

I remain, Sir, your humble servant,

ANDREW MILLAR, M.D., Surgeon R M.

Royal Marine Barracks, Plymouth, 17th Dec., 1849.

UNIVERSITY OF LONDON.

M.D. FIRST EXAMINATION.—PASS EXAMINATION.—1849.

Monday, November 26.—Morning, 10 to 1.

COUSIN AND BUTLER.

Examiner, Rev. H. ALFORD.

1. Give a general account of the Essay on the Human Understanding; specifying its place in the history of Philosophy, the school to which its author belongs, its principal divisions and positions.

2. How does M. Cousin state the order in which psychological inquiries should be undertaken? Has Locke observed this order?

3. "Ma conclusion, que je ramène sans cesse, est que Locke prend évidemment la conséquence pour le principe, l'effet pour la cause. Et remarquez que cette confusion est une nécessité du système de Locke."

Translate this, and exemplify it in the various instances elsewhere adduced by M. Cousin.

4. Define, according to Locke, simple and complex deas:—give M. Cousin's remarks on this definition, and your own criticism of them.

5. "En général, l'école *sensualiste* est *nominaliste*, et l'école *idéaliste* est *réaliste*. Des deux côtés toujours de l'incomplet et de l'exclusif; moitié vérité et moitié erreur."

Translate this; explain *fully* the words in italics, —and M. Cousin's assertions regarding the two schools.

6. What is *Analogy?* Is Butler's argument a fair application of it? Is the following?

"Atqui, ne corporis quidem morbos veteres et diu auctos, nisi per dura et aspera coerceas: corruptus simul et corruptor, æger et flagrans animus, haud levioribus remediis restinguendus est, quam libidinibus ardescit."—*Tacit. Ann.* iii. 54.

7. Give the substance of Butler's remarks on the government of God by rewards and punishments; and of his general conclusion to Part I. of his Analogy.

Monday, November 26.—Morning, 10 to 1.

Examiner, Mr. BURCHAM.

BACON AND STEWART.

1. Enumerate the different *Idola* mentioned by Bacon, and point out the causes or sources of the *Idola Tribus?*

2. Into what three kinds does Bacon divide false philosophy? Give instances of each.

3. The causes of error in philosophical inquiry specified by Bacon. The causes of the slow progress of human knowledge, and especially of mental philosophy, specified by Stewart.

4. Distinguish between the original and acquired perceptions of sight. How do you account for our seeing objects erect by means of inverted images on the retina?

5. Enumerate the laws which regulate the succession of our thoughts. What is meant by *simple* and by *relative suggestion?*

6. Is the moral faculty an original principle of our nature, or is it resolvable into any other more simple principle or principles? Give your reasons for or against either opinion.

COMMENTARY ON A CASE IN MEDICINE. CELSUS DE RE MEDICA. CASE IN MEDICINE.

Monday, November 26.—Afternoon, 3 to 6.

Examiners, Dr. BILLING and Dr. TWEEDIE.

W. S., aged 19, when he applied for advice, stated, that about fifteen days previously, without evident cause, he became indisposed with general symptoms of fever, followed by pain in the right lumbar region, and dry cough. His skin was hot, his pulse quick and sharp, his tongue furred, with loss of appetite and thirst; his bowels were regular, but his urine was scanty and of a deep red colour. When placed on his back, he complained of sensation of tightness and disagreeable pressure, with increased cough, and, on deep inspiration, of pain in the right side of the chest about the inferior angle of the scapula. On the following day he felt acute pain in the right hypochondrium stretching to the loins, which was, however, relieved by the application of a blister; and the cough, which had somewhat abated, was accompanied by slight expectoration. A day or two afterwards, on examining the chest, a gurgling sound, extending from the inferior scapular region to the right hypochondrium, was distinctly audible on inspiration and coughing. General anasarca supervened, and increased somewhat rapidly. In the course of the next few days the expectoration became decidedly purulent, and of a greenish colour, followed by copious general sweating and marked diminution of the dropsical effusion. The strength, however, declined, the cough became less frequent, the expectoration ceased, the breathing was laborious and hurried, the pulse small and rapid, the urine suppressed, the face and extremities livid, and death soon followed.

What was the nature of this disease? What appearances would you expect to find on examination of the body after death? What treatment would you have advised?

Sed inter hæc quidem, proposito metu, spes tamen super est: ad ultima verò jam ventum esse testantur nares acutæ, collapsa tempora, oculi concavi, frigidæ languidæque aures et imis partibus leniter versæ, cutis circa frontem dura et intenta, color aut niger aut perpallidus; multòque magis, si ita hæc sunt, ut neque vigilia præcesserit, neque ventris resolutio, neque inedia. Ex quibus causis interdum hæc species oritur, sed uno die finitur; itaque diutius durans mortis index est. Si verò in morbo vetere jam triduo talis est, in propinquo mors est: magisque, si præter hæc oculi quoque lumen refugiunt et illacrymant; quæque in iis alba esse debent, rubescunt; atque in iisdem venulæ pallent, pituitaque in iis innatans novissimé angulis inhærescit; alterque ex his minor est: iique aut vehementer subsederunt, aut facti tumidiores sunt; perque somnum palpebræ non committuntur, sed inter has ex albo oculorum aliquid apparet, neque id fluens alvus expressit: eædemque palpebræ pallent, et idem pallor labra et nares decolorat; eademque labra et nares, oculique et palpebræ, et supercilia, aliquave ex his pervertuntur: isque propter imbecillitatem jam non audit, aut non videt. Eadem mors denunciatur, ubi æger supinus cubat, eique genua contracta sunt: ubi deorsùm ad pedes subindè delabitur: ubi brachia et crura nudat et inæqualiter dispergit, neque iis calor subest: ubi hiat: ubi assiduè dormit: ubi is qui mentis suæ non est, neque id facere sanus solet, dentibus stridet: ubi ulcus, quod aut antè, aut in ipso morbo natum est, aridum, et aut pallidum aut lividum factum est.

MEDICINE.

Tuesday, November 27.—Morning, 10 to 1.

Examiners, Dr. BILLING and Dr. TWEEDIE.

1. Explain how facial palsy is to be distinguished from palsy of the face arising from cerebral disease.

2. Describe the different forms of chorea, with the various plans of treatment that have been recommended.

3. Describe the symptoms of pneumonia general and local, its anatomical characters, diagnosis, and treatment.

4. Describe the more important organic diseases of the stomach, with the diagnostic symptoms of each.

Afternoon, 3 to 6.

1. Describe the anatomical characters of cirrhosis. Explain its nature and consequences. Sketch its treatment.

2. When blood is discharged by the urethra, mention its sources, and the circumstances which determine the diagnosis.

3. Distinguish narcotic poisoning from apoplexy, and other cerebral diseases accompanied by coma.

4. Describe the diagnostic symptoms, nature and treatment of angina pectoris.

A NEW REMEDY FOR HYDROPHOBIA.—M. Rocher d'Hericourt, who has lately returned from a voyage in Abyssinia, has brought with him numerous specimens of a plant, the root of which, reduced to powder, is a cure for hydrophobia, both in men and animals. Of its virtues M. d'Hericourt had practical proof; four dogs and a man having been bitten by a mad dog, were, by application of the remedy, cured of the hydrophobia which ensued; whilst a fourth dog (bitten at the same time by the same animal), to which the remedy was not given, perished in all the agony of that horrible disease. The virtue of the plant, and the manner of preparing it for use, were explained to the traveller by a potentate of the country, who assured him that it was there generally used, and never failed. The specimens brought over by M. d'Hericourt have been submitted to the Academie des Sciences, and a Committee of that learned body has been appointed to test their efficacy. If, as it is confidently hoped, the plants have not lost their virtue in this European clime, the world will soon be put in possession of the means of curing one of the most frightful diseases to which flesh is heir, and M. Rocher d'Hericourt will have the glory of having conferred an inestimable blessing on mankind.—Paris Correspondent of the *Literary Gazette*.

HEALTH OF LONDON DURING THE WEEK ENDING DEC. 22.

The Deaths registered in the week were 119 below the average. In the corresponding week of the year 1846, 1276 deaths were returned; in that of 1847, 1946 deaths, when the mortality was increased by influenza; and in the same week of 1848, the deaths were 1118. But, though still considerably less than usual, the weekly contingent now shows a tendency to rise to the winter rate of mortality, and the present return shows an increase of 41 on the deaths of the previous week. In three successive weeks ending December 15, the deaths from bronchitis were respectively 60, 86, 89; last week they rose to 110, whilst the average is only 68; from asthma there were 21, 16, 26, and 19 in the last four weeks; and from pneumonia (or inflammation of the lungs) 91, 88, 90, and 81. The mortality from pneumonia, which is less than the average, occurs to a much greater extent among children than aged persons; and the latter class are now the principal sufferers from the increased coldness of the weather. Three men and five women died last week at 90 years and upwards; two of the women had turned 95 years. From diarrhœa and dysentery the deaths were 19; a woman of 70 died on the 16th December, in Great Pulteney street, from debility which succeeded an attack of cholera. All epidemics are less fatal than usual, except measles, which rather exceeds the average.

The mean daily reading of the barometer at Greenwich Observatory was above 30 inches on the last three days of the week; the mean of the week was 29·952. The daily mean temperature, which was 51° on Sunday, gradually fell to 33° on Friday and Saturday; the mean of the week was 42°, rather more than the average of the same week in seven years. The daily mean was about 10° above the average on Sunday and Tuesday, and 6° below it on Friday.

MORTALITY TABLE,

(Metropolis.)

For the Week ending Saturday, Dec. 15, 1849.

CAUSES OF DEATH.	Total.	Average of Five Autumns.
ALL CAUSES	1043	1162
SPECIFIED CAUSES	1040	1158
Zymotic (or Epidemic, Endemic, and Contagious) Diseases	197	307
SPORADIC DISEASES:		
Dropsy, Cancer and other Diseases of uncertain or variable seat	36	49
Tubercular Diseases	155	178
Diseases of the brain, Spinal Marrow, Nerves, and Senses	131	125
Diseases of the Heart and Blood-vessels	39	40
Diseases of the Lungs, and of the other Organs of Respiration	227	214
Diseases of the Stomach, Liver, and other Organs of Digestion	50	65
Diseases of the Kidneys, &c.	10	11
Childbirth, Diseases of the Uterus, &c.	4	10

MEDICAL NEWS.

APOTHECARIES' HALL.—Names of Gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, Dec. 20. 1849:—William Arthur, St. Ives, Huntingdon; George Thomas William Mugliston, West Ham; John Horner, Lincoln; William James Moore, Hales Owen, Shropshire; William Darroch Pennington Swain, Westmoreland; John Humphry, Deal, Kent; Theodore Edward Ladd, Manchester; Henry Miles Cockerton, Rochford, Essex; Jackson Goodenough, Kent, Hampton.

NAVAL APPOINTMENTS.—Assistant Surgeon J. A. Corbett, of the Pluto, serving on the coast of Africa, to be Surgeon; Assisting Surgeon James Fisher, M.D., serving in the Powerful, on the Mediterranean Station, to be Surgeon. Alexander Armstrong, M.D., (1849,) Surgeon, and Henry Piers, (1842, Assist.-Surgeon to the Investigator; David L. Morgan, (1846,) Assist.-Surgeon to the Poictiers, 72 depot ship in ordinary, Chatham.

OBITUARY.—On the 18th inst., at Ripon, Alfred Smith, Esq., Surgeon, aged 42.

PROFESSOR OPOLZER, formerly of Prague, and then of the University of Leipzig, has returned to Austria as surgeon to the Emperor. He is also to direct clinical study at the University of Vienna. For the first time the official announcement has been made in the *Gazette*, with "Herr" placed before the name." Hitherto Austrian etiquette has not allowed such prefix to similar appointments.

PROFESSOR BALASSA, of Pesth, the well-known teacher, who was imprisoned by order of General Haynau, has been set at liberty, and has resumed his Con'cal Le'tu'es.

INDIAN NEWS.—Dr. J. Burnes, K. H. Physician-General, is about to retire from the service. The masonic lodges of the Presidency, have subscribed a sum for the establishment of medals in his honour at the Byculla Schools and Grant College, Bombay, and at the Montrose Academy, Scotland, where he was educated.

DELIRIUM TREMENS.—At the trial of the younger Monkhouse, for attempting to murder his father, one of the surgeons said he attended the prisoner of a delirium tremens fifteen years ago. As the younger Monkhouse was stated in the indictment to be twenty-eight years of age, the attack of delirium tremens must have occurred when he was thirteen—a rather early age for that disease.

LEEDS INFIRMARY.—Mr. Beckwith, the late Secretary to this Institution, has been sentenced to seven years' transportation for embezzling upwards of 1000*l*. from the funds of the Infirmary.

THE CHOLERA AND THE SLAVE-TRADE.—It is said that the cholera has destroyed a great many slaves at the Havannah, and that, in consequence, a number of well-manned and well armed slavers have been fitted out for the African coast to supply the places of those thus destroyed.

CRETINISM.—From a Report which has been presented to the King of Sardinia we gather, that more than 7000 of his subjects are afflicted with cretinism. It exists in twenty-two provinces of the kingdom.

HUGO v. FRANCIS.—This was an action tried in the Crediton County Court, to recover a charge of 2*l*. 10s. for surgical attendance on the defendant, and for sundry boxes of ointment supplied to her. It appeared that the defendant, an elderly lady of considerable property, having a bad leg, was informed that the plaintiff's father had cured a poor woman of a bad leg by a certain ointment. She accordingly sent him for a box of the same, which he very properly refused to supply unless he previously saw the case. He, in consequence, was sent for, and furnished the ointment. He alleged, in his evidence, that he also sent four other boxes, and attended at different times during a twelvemonth, his charge being ultimately 2*l*. 10s., for which, payment being refused, after waiting several years, he took out a summons, describing himself therein as a surgeon-apothecary. On cross-examination it appeared that he held only the license of the Apothecaries' Company, and was not a member of the College of Surgeons. This, the counsel for the defendant contended, must quash the case, as Mr. Hugo had described himself as both; if he were only an apothecary, he said, he could not charge for attendance. For the defence it was asserted that only two boxes of ointment were supplied, and that Mr. Hugo only visited the defendant once. Two medical men stated, on oath, that the proper charge for each box was from 1s. 6d. to 2s. The Judge said that he could not decide that Mr. Hugo was entitled to charge for attendance, but he thought Miss Francis might be

mistaken in the number of boxes of ointment she had had. His judgment was, that Miss Francis pay for five boxes of ointment at 2s. per box, amounting to 10s. It follows from this, that the law of the County Courts differs greatly from that of the Court of Queen's Bench. In the proceedings instituted by Mr. Handey, of the Waterloo-road, against a refractory patient, whose name we at the moment forget, the principle was established that general practitioners, duly qualified, as Mr. Hugo undoubtedly is, were justified in charging for visits and could recover such charges, although medicines were sent at the same time, and moderate charges made for them. The recent case of Vickers v. Skipton also proves the same. That was a case of fracture of the jaw, and the surgeon recovered more than 10s. a visit, besides his charge for medicines. The statement that Mr. Hugo's not holding the diploma of the College of Surgeons disentitled him to charge for attendance, is absurd, to say the least for it. Every qualified medical man is entitled to charge for his attendance. A verdict for 30s., being at the rate of 5s. a visit, in addition to 10s. for the boxes of ointment, would have better met the justice of the case. It is probable, that, if Mr. Hugo were to move for a new trial on these grounds, he would get one, and ultimately increased damages.

THE following has been circulated by the Council of the Provincial Medical Association among its members:—

"In compliance with the resolution passed at the Annual Meeting, held at Worcester, the annexed questions have been carefully framed, and it is earnestly requested by the Council, that the members of the Provincial Medical and Surgical Association will assist in this laudable purpose, by forwarding as full and complete a series of answers as possible, to Mr. Hunt, 26, Bedford-square, London, who has kindly undertaken the inquiry.

"CHARLES HASTINGS,
"President of the Council.

"QUESTIONS.

"1. During the prevalence of the epidemic, has your own neighbourhood, town, or district, been *exempted* from the visitation? If so, can you mention any local circumstances which may account for the exemption? Was the district healthy during the visitation of the cholera about the year 1832, and did circumstances then exist which may be supposed to have protected it?

"2. If the cholera (a) *has* appeared in your district, how many cases have you seen? How many of these have been fatal?

"3. *When* did the disease break out, and *how long* did it prevail? Please to state, generally, whether many persons were simultaneously attacked, or other wise; and whether it commenced contemporaneously in more than one *site* in the same town or district, or whether it appeared to spread from one point only. Were there any peculiar circumstances observable in its local character, or in the course or direction of its advance, which may throw any light upon the important question, whether the disease be of a *contagious* (b) nature or otherwise?

"4. Have you invariably been able to trace the disease to *local impurity of the atmosphere*, or have you seen it attack persons living in a pure air, apart from graveyards and other sources of putrefaction, in well-drained and well ventilated dwellings? In cases of the latter description, if any have been observed, has there been any intercourse with the sick, which may tend to establish the doctrine of *contagion*, or the reverse.

"5. Did the cholera ever appear in your neighbourhood *with or without* the general and contemporaneous appearance of the *milder forms* of disease—diarrhœa, bilious cholera, &c.? Has dysentery or typhus been prevalent or otherwise?

"6. Were its ravages indiscriminate as to personal vigour, age, sex, station, occupation, &c; or might the attacks be traced to some *predisposing personal cause*,—as weak bowels, intemperance, debility, fear, errors in diet, uncleanly or sedentary habits, or impaired health from any cause?

"7. Were 'premonitary' symptoms of general occurrence, or did the disease frequently appear suddenly in the malignant form with violent cramps, vomiting and purging, 'rice-water' dejections, and rapid collapse?

"8. Did the symptoms differ from those generally observed, and frequently described? Had the disease any peculiar type, either of mildness or malignity?

"9. Are you aware of any exempting circumstances of any description which have uniformly protected certain individuals from the disease,—such as trades, habits, diet, &c., not inclusive of local habitation?

"10. Can you throw any light on the *physical origin* of remote cause of the recent or former visitation? Are you able to say, from your own observation, that the general symptoms and history of both are similar? Have you instituted any researches into the density, humidity, temperature, or electro-magnetic phenomena of the atmosphere? Have you observed the progress of the cholera to be arrested by storms, wind, or rain?

"11. Have you made any *post-mortem* examinations of fatal cases of cholera, and with what result? Do you know of any circumstances which justify the immediate interment of the dead? Did you ever observe cholera patients show signs of organic life for hours or days after apparent death?

"12. Can you describe any method or principle of treatment which has proved successful in so large a number of cases of *cholera*, as to commend it to universal adoption? If so, has not the method frequently failed in other hands, and can you explain the cause of failure?

"13. What mode of *treating* the epidemic *diarrhœa* and premonitory symptoms generally have you found most successful?

"14. Can you suggest any means of preventing or arresting the spread of the disease, in the event of any future outbreak?

"What is your opinion as to the propriety of removing the inhabitants, who have not taken the disease, from the infected dwellings to houses of refuge, in situations where the presumed causes of the disease are not in operation?"

(a) It is proposed, to avoid confusion of terms, to restrict the term *cholera* to cases of vomiting, purging, cramp, and rice-water evacuations; the term, *bilious cholera*, to vomiting and purging of bile, with cramps; and the term, *diarrhœa*, to profuse alvine discharges, without either vomiting or cramps.

"(b) A house or district may be *infected*, so as to spread a disease not strictly *contagious*. Respondents are therefore requested to confine the latter term to evidence of communication by personal approach or contact.

TREATMENT OF CHOLERA AT ST. BARTHOLOMEW'S HOSPITAL.—The first admission of cholera patients into this Institution commenced on the 17th of June last, and terminated on the 6th of October. During this time, 478 cases were treated by the three physicians and the apothecary, viz.:—253 males, and 225 females. The deaths were 199.

	Patients.	Died.
There were under the care of Dr. Hue	145	63
Ditto .. .. Dr. Roupell	170	63
Ditto .. .. Dr. Burrows	163	73
	478	199

The mode of treatment was as follows:—Immediately, on admission, the patient was placed in a hot-bath, and, as soon as removed, wrapped in hot blankets; friction was then perseveringly applied, suitable medicines administered, and the urgent thirst alleviated with "ice cold water." Most of the cases, when admitted, exhibited the disease in its most virulent form.

PAROCHIAL ILLIBERALITY.—We have often had occasion to condemn Boards of Guardians for their parsimony; but the following instance is so disgraceful, that we can hardly give credit to the report. It appears, that a poor woman named Louisa Eames, nursed two cholera cases for thirteen days and seven nights, for which she made the charge of 10s. being at the rate of 6d. for each twelve hours. Her attention was described by the surgeon as unremitting, and yet these save-all Guardians, instead of paying her 2s. 6d. for each twelve hours, as they ought to have done, after considerable deliberation, cut down her claim to 7s. 6d. To the credit of the Clerk of the Board, and two of the members, one a clergyman, they advocated the payment of an additional 10s. to her bill. Surely when the attention of the Poor-law Commissioner has been directed to this matter, he will overrule the decision of the guardians; if not, the parishioners themselves ought to take up the matter, and, moreover, should expel those recusant members of the Board, who value such service at so paltry a rate. In private life, we believe, there is not a member of any board of guardians who would not be ashamed to offer a nurse less than 5s. a day under such circumstances. Eames made a monstrously low demand,—6d. a day; to cut that down to 4½d. was atrociously mean. Perhaps they call this doing their duty to their constituents.

TO CORRESPONDENTS.

Letters "On Certain Effects of an Inveterate Habit of Smoking," by Mr. Levison, of Brighton; on "the Cholera at Penzance," by Mr. Couch; from X. Y., on "the Commissioners in Lunacy"; Dr. Thompson, of Tyrone; Mr. Startin on "Glycerine;" Dr. Roe, of Plymouth; M.D., Lond., on "Professor Jamieson's late Lecture at Aberdeen,"—are in print. A press of matter must be our excuse for delaying their publication.

"Mr. A. McClure, of H.M.S. 'Indefatigable,'" informs us, that he had prepared a reply to Mr. Chubb's letter in our last; but, understanding that in our present Number we should probably publish a communication from Dr. Millar, surgeon of the Royal Marines, on the same subject, he begs to delay it until he has had the opportunity of replying to both at the same time, and thus not needlessly to occupy our columns.

We regret that we cannot in the present Number comply with the request of our valued friend at Birmingham. We will do so next week.

"Mr. Wells, of Crewkerne," requests we will insert, in an early Number of our Journal, "a list of the different prize subjects in medicine and surgery, now offered for competition by the different medical societies, &c., with a short sketch of the condition under which they are to be competed for." The suggestion is good, and we will endeavour to comply with the request of our respected correspondent.

"Mr. Hullmandell" has forwarded his Razor-strop *for review*. It has already been favourably noticed by Dr. Ure, Mr. Lewis Thompson, of Lambeth, Mr. Erasmus Wilson, Mr. Crofton Croker, of the Admiralty, and Monsieur Roux, of the French Embassy. We will send it to our roughest-bearded contributor, and publish his report.

"Anti-Humbug."—We think, "enough is as good as a feast."

Will Mr. Lancaster kindly repeat his question.

"Mr. J. A. Coffey," inventor of the Esculapian Still and Condenser, must make us acquainted with his invention, and shew us its *professional* advantages, before we can undertake to introduce it to our readers.

"Viator" asks information concerning the appointment of surgeon to an emigrant vessel, and the duties which devolve upon a medical man when appointed. No passenger ship having fifty persons on board, if the length of the voyage exceed twelve weeks, or whatever the length of the voyage when a hundred persons are on board, can go to sea without having a duly qualified Physician, Surgeon, or Apothecary on board, and rated on the ship's articles. It is necessary that the medical practitioner be approved by the emigration officer at the port of clearance. No passenger-ship bound to North America, having a hundred persons on board, can proceed on the voyage without a medical officer. 2. The owner of the vessel must provide a medicine-chest, with a proper supply of medicine, instruments, and other things necessary for diseases and accidents, incident to sea voyages; such chests to be examined and approved by a medical practitioner appointed by the emigration officer at the port of clearance. 3. The surgeon has authority to enforce all rules and regulations for the preservation of the health of the passengers.

"A Young Navy Surgeon" asks our opinion in reference to the gaseous emanations from the bilge-water of ships. There is no doubt that the gases, whether offensive or not, which escape from foul holds, conduce greatly to generate disease. In the Eclair, though the holds were thought to be perfectly clean, they were found subsequently to have a collection of mud three inches deep, upon that portion of her bottom occupied by the boilers and machinery. When the holds of the Growler were opened at Woolwich, after her return from Africa, two men who slept over the hatchway were seized with a most malignant fever, which proved fatal in a few days. Foul holds are something like foul sewers.

"Provincial" wishes to know the best solvent of arsenous acid. We believe hydrochloric acid, which takes up a considerable quantity, especially when heated.

"Dental" asks us the most frequent causes of necrosis of the teeth. Mechanical violence or inflammation of the alveoli; it may also be produced by salivation and fever.

"Leonard B." inquires the best method of saturating water with sulphuretted hydrogen gas. Distilled water should be used at a low temperature, and the gas rapidly passed into it. Two stoppered bottles should be employed, being one-third full of water. The gas is then transmitted into one till it is completely filled with it, the atmospheric air being displaced, then transfer the gas-delivering tube to the second bottle, and immediately close the mouth of the other, and shake it so as to bring the gas in contact with the water. During this time the second bottle will be filled with the sulphuretted hydrogen, and the tube conveying it being again transferred to the other, this bottle just filled is agitated with its contents till absorption is completed. The process is carried on till no more gas is absorbed by the water. The saturated water is then put into small bottles, which should be completely filled, well stopped, and kept with their mouths inverted, in a vessel of cold water.

"Pharmacien."—Mucilage is much better than an alkali for making an emulsion with castor-oil or copaiba; but an alkali is better with oil of almonds. It is said that a small portion of borax greatly improves an emulsion. We would not, however, recommend the addition of this salt.
